Python Scripting for Spatial Data Processing.

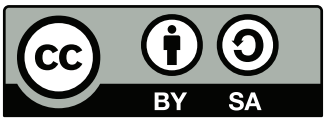
Pete Bunting and Daniel Clewley

Teaching notes on the MSc's in Remote Sensing and GIS.

March 22, 2013

Aberystwyth University

Institute of Geography and Earth Sciences.



Acknowledgements

The authors would like to acknowledge to the supports of others but specifically (and in no particular order) Prof. Richard Lucas, Sam Gillingham (developer of RIOS and the image viewer) and Neil Flood (developer of RIOS) for their support and time.

Authors

Peter Bunting

Dr Pete Bunting joined the Institute of Geography and Earth Sciences (IGES), Aberystwyth University, in September 2004 for his Ph.D. where upon completion in the summer of 2007 he received a lectureship in remote sensing and GIS. Prior to joining the department, Peter received a BEng(Hons) in software engineering from the department of Computer Science at Aberystwyth University. Pete also spent a year working for Landcare Research in New Zealand before rejoining IGES in 2012 as a senior lecturer in remote sensing.

Daniel Clewley

Dr Dan Clewley joined IGES in 2006 undertaking an MSc in Remote Sensing and GIS, following his MSc Dan undertook a Ph.D. entitled Retrieval of Forest Biomass and Structure from Radar Data using Backscatter Modelling and Inversion under the supervision of Prof. Lucas and Dr. Bunting. Prior to joining the department Dan completed his BSc(Hons) in Physics within Aberystwyth University. Dan is currently a post-doc researcher at the University of Southern California.

Chapter 1

Introduction

1.1 Background

1.1.1 What is Python?

Python is a high level scripting language which is interpreted, interactive and object-oriented. A key attribute of python is its clear and understandable syntax which should allow you to quickly get up to speed and develop useful application, while the syntax is similar enough to lower level languages, for example C/C++ and Java, to provide a background from which you can grow your expertise. Python is also a so called memory managed language, meaning that you the developer are not directly in control of the memory usage within your application, making development much simpler. That is not saying that memory usage does not need to be considered and you, the developer, cannot influence the memory footprint of your scripts but these details are out of the scope of this course. Python is cross-platform with support for Windows, Linux, Mac OS X and most other UNIX platforms. In addition, many libraries (e.g., purpose built and external C++ libraries) are available to python and it has become a very popular language for many applications, including on the internet and within remote sensing and GIS.

1.1.2 What can it be used for?

Python can be used for almost any task from simple file operations and text manipulation to image processing. It may also be used to extend the functionality of other, larger applications.

1.1.3 A word of warning

There are number of different versions of python and these are not always compatible. For these worksheets we will be using version 2.X (at the time of writing the latest version is 2.7.3), although versions of 3.X are available these are currently not widely supported but support is growing.

1.2 Example of Python in use

1.2.1 Software in Python

Many applications have been built in python and a quick search of the web will reveal the extent of this range. Commonly, applications solely developed in python are web applications, run from within a web server (e.g., Apache; `http://httpd.apache.org` with `http://www.modpython.org`) but Desktop applications and data processing software such as 'viewer' (`https://bitbucket.org/chchrsc/viewer`) and RIOS (`https://bitbucket.org/chchrsc/rios`) have also been developed.

In large standalone applications python is often used to facilitate the development of plugins or extensions to application. Examples of python used in this form include ArcMap and SPSS.

For a list of applications supporting or written in python refer to the following website `http://en.wikipedia.org/wiki/Python_software`.

1.3 Python Libraries

Many libraries are available to python. Libraries are collections of functions which can be called from your script(s). Python provides extensive libraries (`http://docs.python.org/lib/lib.html`) but third parties have also developed additional libraries to provide specific functionality (e.g., plotting). A list of available libraries is available from `http://wiki.python.org/moin/UsefulModules` and by following the links provides on the page.

The following sites provide links to libraries and packages specific to remote sensing and GIS, many of which are open source with freely available software packages and libraries for use with python.

- `http://freegis.org`
- `http://opensourcegis.org`
- `http://www.osgeo.org`

1.4 Installing Python

For this tutorial Python alongside the libraries GDAL (`http://www.gdal.org`), numpy (`http://www.numpy.org`), scipy (`http://www.scipy.org`), RIOS (`https://bitbucket.org/chchrsc/rios`) and matplotlib (`http://matplotlib.sourceforge.net`) are required. Python, alongside these packages, can be installed on almost any platform. For Windows a python package which includes all the libraries other than RIOS required for this worksheet is available, for free, as a simple download from `http://www.pythonxy.com`. To install this package download the installation file and run selecting a full installation.

For further details of the installation process please see the project website `http://www.pythonxy.com`.

PythonXY is also available for Linux (`https://code.google.com/p/pythonxy-linux`) but all these packages are commonly available for the Linux platform through the distributions package management systems.

For Mac OSX the KyngChaos Wiki `http://www.kyngchaos.com/software/frameworks` makes various binary packages available for installing GDAL etc. and the enThought `http://www.enthought.com` python distribution also includes many of the tools you require.

1.5 Text Editors

To write your Python scripts a text editor is required. A simple text editor such as Microsoft's Notepad will do but it is recommended that you use a syntax aware editor that will colour, and in some cases format, your code automatically. There are many text editors available for each operating system and it is up to you to choose one to use, although recommendations have been made below.

1.5.1 Windows

The recommend editor is Spyder which installed within the python(x,y) package. From within Spyder you can directly run your python scripts (using the run button), additionally it will alert you to errors within your scripts before you run them. Alternatively, the notepad++ (`http://notepad-plus.sourceforge.net`) text editor can also be used. Notepad++ is a free to use open source text editor and can therefore be downloaded and installed onto any Windows PC. If you use this editor it is recommended you change the settings for python to use spaces instead of tabs using the following steps:

1. Go to Setting – Preferences
2. Select 'Language Menu / Tab Settings'
3. Under 'Tab Settings' for python tick 'Replace by space'

1.5.2 Linux

Under Linux either the command line editor ne (nice editor), vi or its graphic interface equivalent gvim is recommend but kdeveloper, gedit and many others

are also good choices.

1.5.3 Mac OSX

Under Mac OSX either BBEdit, SubEthaEdit or TextMate are recommended, while the freely available TextWrangler is also a good choice. The command line editors ne and vi are also available under OS X.

1.5.4 Going between Windows and UNIX

If you are writing your scripts on Windows and transferring them to a UNIX/Linux machine to be executed (e.g., a High Performance Computing (HPC) environment) then you need to be careful with the line ending (the invisible symbol defining the end of a line within a file) as these are different between the various operating systems. Using notepad++ line ending can be defined as UNIX and this is recommended where scripts are being composed under Windows.

Alternatively, if RSGISLib is installed then the command flip can be used to convert the line ending, the example below converts to UNIX line endings.

```
flip -u InputFile.py
```

1.6 Starting Python

Python may be started by opening a command window and typing:

```
python
```

(Alternatively select python(x,y) – Command Prompts – Python interpreter from the windows start menu).

This opens python in interactive mode. It is possible to perform some basic maths try:

```
>>> 1 + 1
2
```

To exit type:

```
>>>exit()
```

To perform more complex tasks in python often a large number of commands are required, it is therefore more convenient to create a text file containing the commands, referred to as a 'script'

1.6.1 Indentation

There are several basic rules and syntax which you need to know to develop scripts within python. The first of which is code layout. To provide the structure of the script Python uses indentation. Indentation can be in the form of tabs or spaces but which ever is used needs to be consistent throughout the script. The most common and recommend is to use 4 spaces for each indentation. The example given below shows an if-else statement where you can see that after the if part the statement which is executed if the if-statement is true is indented from rest of the script as with the corresponding else part of the statement. You will see this indentation as you go through the examples and it is important that you follow the indentation shown in the examples or your scripts will not execute.

```
1 if␣x␣==␣1:
2 ␣␣␣␣x␣=␣x␣+␣1
3 else:
4 ␣␣␣␣x␣=␣x␣-␣1
```

1.6.2 Keywords

As with all scripting and programming languages python has a set of keywords, which have special meanings to the compiler or interpreter when the code is executed. As with all python code, these keywords are case sensitive i.e., 'else' is a keyword but 'Else' is not. A list of pythons keywords is given below:

Table 1.1: Keywords within the Python language

and	as	assert	break
class	continue	def	del
elif	else	exec	except
finally	for	from	global
if	import	in	is
lambda	not	or	pass
print	raise	return	try
while	with	yield	

1.6.3 File Naming

It is important that you use sensible and identifiable names for all the files you generate throughout these tutorial worksheets otherwise you will not be able to identify the script at a later date. Additionally, it is highly recommended that you do not included spaces in file names or in the directory path you use to store the files generated during this tutorial.

1.6.4 Case Sensitivity

Something else to remember when using python, is that the language is case sensitivity therefore if a name is in lowercase then it needs to remain in lowercase everywhere it is used.

For example:

```
VariableName is not the same as variablename
```

1.6.5 File paths in examples

In the examples provided (in the text) file paths are given as ‘./PythonCourse/TutorialX/File.xxx’. When writing these scripts out for yourself you will need to update these paths to the location on your machine where the files are located (e.g., /home/pete.bunting or C:\). Please note that it is recommended that you do not have any spaces within your file paths. In the example (answer) scripts provided no file path has been

written and you will therefore need to either save input and output files in the same directory as the script or provide the path to the file. Please note that under Windows you need to insert a double slash (i.e., \\) within the file path as a single slash is an escape character (e.g., \n for new line) within strings.

1.6.6 Independent Development of Scripts

There is a significant step to be made from working your way through notes and examples, such as those provided in this tutorial, and independently developing your own scripts from scratch. Our recommendation for this, and when undertaking the exercises from this tutorial, is to take it slowly and think through the steps you need to undertake to perform the operation(s) you need.

I would commonly first 'write' the script using comments or on paper breaking the process down into the major steps required. For example, if I were asked to write a script to uncompress a directory of files into another directory I might write the following outline, where I use indentation to indicate where a process is part of the parent:

```
1  # Get input directory (containing the compressed files)
2
3  # Get output directory (where the files, once uncompressed, will be placed).
4
5  # Retrieve list of all files (to be uncompressed) in the input directory.
6
7  # Iterator through input files, uncompressing each in turn.
8          # Get single file from list
9          # create command line command for the current file
10         # execute command
```

By writing the process out in this form it makes translating this into python much simpler as you only need to think of how to do small individual elements in python and not how to do the whole process in one step.

1.6.7 Getting Help

Python provides a very useful help system through the command line. To get access to the help run python from the terminal

```
> python
```

Then import the library want to get help on

```
>>> import math
```

and then run the help tool on the whole module

```
>>> import math
>>> help(math)
```

or on individual classes or functions within the module

```
>>> import osgeo.gdal
>>> help(math.cos)
```

To exit the help system just press the 'q' key on the keyboard.

Chapter 2

The Basics

2.1 Hello World Script

To create your first python script, create a new text file using your preferred text editor and enter the text below:

```
1  #! /usr/bin/env python
2
3  ########################################
4  # A simple Hello World Script
5  # Author: <YOUR NAME>
6  # Emai: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 print 'Hello World'
```

Save your script to file (e.g., helloworld.py) and then run it either using a command prompt (Windows) or Terminal (UNIX), using the following command:

```
> python helloworld.py
Hello World
```

To get a command prompt under Windows type 'cmd' from the run dialog box in the start menu (Start – run), further hints for using the command prompt are given below. Under OS X, terminal is located in within the 'Utilities' folder in 'Applications'. If you are using Spyder to create your Python scripts you can run by clicking the run button.

Hints for using the Windows command line
'cd' allows you to change directory, e.g.,

```
cd directory1\directory2
```

'dir' allows you to list the contents of a directory, e.g.,

```
dir
```

To change drives, type the drive letter followed by a colon, e.g.,

```
D:
```

If a file path has spaces, you need to use quote, e.g, to change directory:

```
cd "Directory with spaces in name\another directory\"
```

2.2 Comments

In the above script there is a heading detailing the script function, author, and version. These lines are preceded by a hash (#), this tells the interpreter they are comments and are not part of the code. Any line starting with a hash is a comment. Comments are used to annotate the code, all examples in this tutorial use comments to describe the code. It is recommended you use comments in your own code.

2.3 Variables

The key building blocks within all programming languages are variables. Variables allow data to be stored either temperately for use in a single operation or throughout the whole program (global variables). Within python the variable data type does not need to be specified and will be defined by the first assignment. Therefore, if the first assignment to a variable is an integer (i.e., whole number) then that variable will be an integer for the remained of the program. Examples defining variables are provided below:

```
name = 'Pete' # String
age = 25 # Integer
height = 6.2 # Float
```

2.3.1 Numbers

There are three types of numbers within python:

Integers are the most basic form of number, contain only whole numbers where calculation are automatically rounded to provide whole number answers.

Decimal or floating point numbers provide support for storing all those number which do not form a whole number.

Complex provide support for complex numbers and are defined as $a + bj$ where a is the real part and b the imaginary part, e.g., $4.5 + 2.5j$ or $4.5 - 2.5j$ or $-4.5 + 2.5j$

The syntax for defining variables to store these data types is always the same as python resolves the suitable type for the variable. Python allows a mathematical operations to be applied to numbers, listed in Table reftab:maths

2.3.2 Boolean

The boolean data type is the simplest and just stores a true or false value, an example of the syntax is given below:

Table 2.1: The mathematical functions available within python.

Function	Operation
x + y	x plus y
x - y	x minus y
x * y	x multiplied by y
x / y	x divided by y
x ** y	x to the power of y
int(obj)	convert string to int
long(obj)	convert string to long
float(obj)	convert string to float
complex(obj)	convert string to complex
complex(real, imag)	create complex from real and imaginary components
abs(num)	returns absolute value
pow(num1, num2)	raises num1 to num2 power
round(float, ndig=0)	rounds float to ndig places

```
moveForwards = True
moveBackwards = False
```

2.3.3 Text (Strings)

To store text the string data type is used. Although not a base data type like a float or int a string can be used in the same way. The difference lies in the functions available to manipulate a string are similar to those of an object. A comprehensive list of functions is available for a string is given in the python documentation `http://docs.python.org/lib/string-methods.html`.

To access these functions the string modules needs to be imported as shown in the example below. Copy this example out and save it as StringExamples.py. When you run this script observe the change in the printed output and using the python documentation to identify what each of the functions lstrip(), rstrip() and strip() do.

```
1 #! /usr/bin/env python
2
3 ########################################
4 # Example with strings
```

```
5  # Author: <YOUR NAME>
6  # Emai: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 import string
12
13 stringVariable = '       Hello World      '
14
15 print '\'' +  stringVariable + '\''
16
17 stringVariable_lstrip = stringVariable.lstrip()
18 print 'lstrip: \'' +  stringVariable_lstrip + '\''
19
20 stringVariable_rstrip = stringVariable.rstrip()
21 print 'rstrip: \'' +  stringVariable_rstrip + '\''
22
23 stringVariable_strip = stringVariable.strip()
24 print 'strip: \'' +  stringVariable_strip + '\''
```

2.3.4 Example using Variables

An example script illustrating the use of variables is provided below. It is recommend you copy this script and execute making sure you understand each line. In addition, try making the following changes to the script:

1. Adding your own questions.
2. Including the persons name within the questions.
3. Remove the negative marking.

```
1  #! /usr/bin/env python
2
3  ########################################
4  # A simple script illustrating the use of
5  # variables.
6  # Author: <YOUR NAME>
```

```
7  # Emai: <YOUR EMAIL>
8  # Date: DD/MM/YYYY
9  # Version: 1.0
10 ########################################
11
12 score = 0 # A variable to store the ongoing score
13
14 # print is used to 'print' the text to the command line
15 print '################################################'
16 print 'Sample Python program which asks the user a few ' \
17       'simple questions.'
18 print '################################################'
19
20 # raw_input is used to retrieve user input from the
21 # command line
22 name = raw_input('What is your name?\n')
23
24 print 'Hello ' + name + '. You will be now asked a series' \
25 ' of questions please answer \'y\' for YES and \'n\' for ' \
26 'NO unless otherwise stated.'
27
28 print 'Question 1:'
29 answer = raw_input('ALOS PALSAR is a L band spaceborne SAR.\n')
30 if answer == 'y': # test whether the value returned was equal to y
31     print 'Well done'
32     score = score + 1 # Add 1 to the score
33 else: # if not then the anser must be incorrect
34     print 'Bad Luck'
35     score = score - 1 # Remove 1 from the score
36
37 print 'Question 2:'
38 answer = raw_input('CASI provides hyperspectral data in ' \
39 'the Blue to NIR part of the spectrum.\n')
40 if answer == 'y':
41     print 'Well done'
42     score = score + 1
43 else:
44     print 'Bad Luck'
45     score = score - 1
46
47 print 'Question 3:'
```

```
48 answer = raw_input('HyMap also only provides data in the ' \
49 'Blue to NIR part of the spectrum.\n')
50 if answer == 'y':
51     print 'Bad Luck'
52     score = score - 1
53 else:
54     print 'Well done'
55     score = score + 1
56
57 print 'Question 4:'
58 answer = raw_input('Landsat is a spaceborne sensor.\n')
59 if answer == 'y':
60     print 'Well done'
61     score = score + 1
62 else:
63     print 'Bad Luck'
64     score = score - 1
65
66 print 'Question 5:'
67 answer = raw_input('ADS-40 is a high resolution aerial ' \
68 'sensor capturing RGB-NIR wavelengths.\n')
69 if answer == 'y':
70     print 'Well done'
71     score = score + 1
72 else:
73     print 'Bad Luck'
74     score = score - 1
75
76 print 'Question 6:'
77 answer = raw_input('eCognition is an object oriented ' \
78 'image analysis software package.\n')
79 if answer == 'y':
80     print 'Well done'
81     score = score + 1
82 else:
83     print 'Bad Luck'
84     score = score - 1
85
86 print 'Question 7:'
87 answer = raw_input('Adobe Photoshop provides the same ' \
88 'functionality as eCognition.\n')
```

```
89  if answer == 'y':
90      print 'Bad Luck'
91      score = score - 1
92  else:
93      print 'Well done'
94      score = score + 1
95
96  print 'Question 8:'
97  answer = raw_input('Python can be executed within ' \
98  'the a java virtual machine.\n')
99  if answer == 'y':
100     print 'Well done'
101     score = score + 1
102 else:
103     print 'Bad Luck'
104     score = score - 1
105
106 print 'Question 9:'
107 answer = raw_input('Python is a scripting language ' \
108 'not a programming language.\n')
109 if answer == 'y':
110     print 'Well done'
111     score = score + 1
112 else:
113     print 'Bad Luck'
114     score = score - 1
115
116 print 'Question 10:'
117 answer = raw_input('Aberystwyth is within Mid Wales.\n')
118 if answer == 'y':
119     print 'Well done'
120     score = score + 1
121 else:
122     print 'Bad Luck'
123     score = score - 1
124
125 # Finally print out the users final score.
126 print name + ' you got a score of ' + str(score)
```

2.4 Lists

Each of the data types outlined above only store a single value at anyone time, to store multiple values in a single variable a sequence data type is required. Python offers the List class, which allows any data type to be stored in a sequence and even supports the storage of objects of different types within one list. The string data type is a sequence data type and therefore the same operations are available.

List are very flexible structures and support a number of ways to create, append and remove content from the list, as shown below. Items in the list are numbered consecutively from 0-n, where n is one less than the length of the list.

Additional functions are available for List data types (e.g., len(aList), aList.sort(), aList.reverse()) and these are described in `http://docs.python.org/lib/typesseq.html` and `http://docs.python.org/lib/typesseq-mutable.html`.

2.4.1 List Examples

```
1  #! /usr/bin/env python
2
3  ########################################
4  # Example with lists
5  # Author: <YOUR NAME>
6  # Emai: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 # Create List:
12 aList = list()
13 anotherList = [1, 2, 3, 4]
14 emptyList = []
15
16 print aList
17 print anotherList
18 print emptyList
19
```

```
20 # Adding data into a List
21 aList.append('Pete')
22 aList.append('Dan')
23 print aList
24
25 # Updating data in the List
26 anotherList[2] = 'three'
27 anotherList[0] = 'one'
28 print anotherList
29
30 # Accessing data in the List
31 print aList[0]
32 print anotherList[0:2]
33 print anotherList[2:3]
34
35 # Removing data from the List
36 del anotherList[1]
37 print anotherList
38
39 aList.remove('Pete')
40 print aList
```

2.4.2 n-dimensional list

Additionally, n-dimensional lists can be created by inserting lists into a list, a simple example of a 2-d structure is given below. This type of structure can be used to store images (e.g., the example given below would form a grey scale image) and additions list dimensions could be added for additional image bands.

```
1 #! /usr/bin/env python
2
3 ########################################
4 # Example with n-lists
5 # Author: <YOUR NAME>
6 # Emai: <YOUR EMAIL>
7 # Date: DD/MM/YYYY
8 # Version: 1.0
9 ########################################
```

```
10
11 # Create List:
12 aList = [
13 [1,1,1,1,1,1,1,1,1,1,1,1,1,1],
14 [1,1,0,0,1,1,1,1,1,0,0,1,1,1],
15 [1,1,0,0,1,1,1,1,1,0,0,1,1,1],
16 [1,1,1,1,1,1,1,1,1,1,1,1,1,1],
17 [1,1,1,1,1,1,0,1,1,1,1,1,1,1],
18 [1,1,1,1,1,1,0,1,1,1,1,1,1,1],
19 [1,1,1,1,1,0,0,0,1,1,1,1,1,1],
20 [1,0,1,1,1,1,1,1,1,1,1,1,0,1],
21 [1,0,1,1,1,1,1,1,1,1,1,1,0,1],
22 [1,1,0,0,0,0,0,0,0,0,0,0,1,1],
23 [1,1,1,1,1,1,1,1,1,1,1,1,1,1]
24 ]
25
26 print aList
```

2.5 IF-ELSE Statements

As already illustrated in the earlier quiz example the ability to make a decision is key to any software. The basic construct for decision making in most programming and scripting languages are if-else statements. Python uses the following syntax for if-else statements.

```
if <logic statement>:
    do this if true
else:
    do this

if <logic statement>:
    do this if true
elif <logic statement>:
    do this if true
elif <logic statement>:
    do this if true
else
    do this
```

Logic statements result in a true or false value being returned where if a value of true is returned the contents of the if statement will be executed and remaining parts of the statement will be ignored. If a false value is returned then the if part of the statement will be ignored and the next logic statement will be analysis until either one returns a true value or an else statement is reached.

2.5.1 Logic Statements

Table 2.2 outlines the main logic statements used within python in addition to these statements functions which return a boolean value can also be used to for decision making, although these will be described in later worksheets.

Table 2.2: Logic statements available within python

Function	Operation	Example
==	equals	expr1 == expr2
¿	greater than	expr1 ¿ expr2
¡	less than	expr1 ¡ expr2
¿=	greater than and equal to	expr1 ¿= expr2
¡=	less than and equal to	expr1 ¡= expr2
not	logical not	not expr
and	logical and	expr1 and expr2
or	logical or	expr1 or expr2
is	is the same object	expr1 is expr2

2.6 Looping

In addition to the if-else statements for decision making loops provide another key component to writing any program or script. Python offers two forms of loops, while and for. Each can be used interchangeably given the developers preference and available information. Both types are outlined below.

2.6.1 while Loop

The basic syntax of the while loop is very simple (shown below) where a logic statement is used to terminate the loop, when false is returned.

```
while <logic statement> :
    statements
```

Therefore, during the loop a variable in the logic statement needs to be altered allowing the loop to terminate. Below provides an example of a while loop to count from 0 to 10.

```
1  #! /usr/bin/env python
2
3  ########################################
4  # A simple example of a while loop
5  # Author: <YOUR NAME>
6  # Emai: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 count = 0
12 while count <= 10:
13     print count
14     count = count + 1
```

2.6.2 for Loop

A for loop provides similar functionality to that of a while loop but it provides the counter for termination. The syntax of the for loop is provided below:

```
1 for <iter_variable> in <iterable>:
2     statements
```

The common application of a for loop is for the iteration of a list and an example if this is given below:

```
1  #! /usr/bin/env python
2
```

```
3  ########################################
4  # A simple example of a for loop
5  # Author: <YOUR NAME>
6  # Emai: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 aList = ['Pete', 'Richard', 'Johanna', 'Philippa', 'Sam', 'Dan', 'Alex']
12
13 for name in aList:
14         print 'Current name is: ' + name
```

A more advance example is given below where two for loops are used to iterate through a list of lists.

```
1  #! /usr/bin/env python
2
3  ########################################
4  # Example with for loop and n-lists
5  # Author: <YOUR NAME>
6  # Emai: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 # Create List:
12 aList = [
13 [1,1,1,1,1,1,1,1,1,1,1,1,1,1,1],
14 [1,1,0,0,1,1,1,1,1,0,0,1,1,1],
15 [1,1,0,0,1,1,1,1,1,0,0,1,1,1],
16 [1,1,1,1,1,1,1,1,1,1,1,1,1,1,1],
17 [1,1,1,1,1,1,0,1,1,1,1,1,1,1],
18 [1,1,1,1,1,1,0,1,1,1,1,1,1,1],
19 [1,1,1,1,1,0,0,0,1,1,1,1,1,1],
20 [1,0,1,1,1,1,1,1,1,1,1,1,0,1],
21 [1,0,1,1,1,1,1,1,1,1,1,1,0,1],
22 [1,1,0,0,0,0,0,0,0,0,0,0,1,1],
23 [1,1,1,1,1,1,1,1,1,1,1,1,1,1]
24 ]
```

```
25
26 for cList in aList:
27         for number in cList:
28                 print number,
29         print
```

2.7 Exercises

During this tutorial you should have followed through each of the examples and experimented with the code to understand each of components outlined. To test your understanding of all the material, you will now be asked to complete a series of tasks:

1. Update the quiz so the questions and answers are stored in lists which are iterated through as the script is executed.
2. Create a script that loops through the smiling face 2-d list of lists flipping it so the face is up side down.

2.8 Further Reading

- An Introduction to Python, G. van Rossum, F.L. Drake, Jr. Network Theory ISBN 0-95-416176-9 (Also available online - `http://docs.python.org/2/tutorial/`) - Chapters 4 and 5.
- Spyder Documentation – `http://packages.python.org/spyder/`
- Python Documentation – `http://www.python.org/doc/`
- Core Python Programming (Second Edition), W.J. Chun. Prentice Hall ISBN 0-13-226993-7
- How to think Like a Computer Scientist: Python Edition – `http://www.greenteapress.com/thinkpython/`

Chapter 3

Text Processing

3.1 Read a Text File

An example of a script to read a text file is given below, copy this example out and use the numbers.txt file to test your script. Note, that the numbers.txt file needs to be within the same directory as your python script.

```
1  #! /usr/bin/env python
2
3  ########################################
4  # A simple example reading in a text file
5  # two versions of the script are provided
6  # to illustrate that there is not just one
7  # correct solution to a problem.
8  # Author: <YOUR NAME>
9  # Email: <YOUR EMAIL>
10 # Date: DD/MM/YYYY
11 # Version: 1.0
12 ########################################
13
14 import string
15
16 # 1) Splits the text file into individual characters
17 # to identify the commas and parsing the individual
18 # tokens.
```

```
19 numbers = list()
20 dataFile = open('numbers.txt', 'r')
21
22 for eachLine in dataFile:
23     #print eachLine
24     tmpStr = ''
25     for char in eachLine:
26         #print char
27         if char.isdigit():
28             tmpStr += char
29         elif char == ',' and tmpStr != '':
30             numbers.append(int(tmpStr))
31             tmpStr = ''
32     if tmpStr.isdigit():
33         numbers.append(int(tmpStr))
34
35 print numbers
36 dataFile.close()
37
38 # 2) Uses the string function split to line from the file
39 # into a list of substrings
40 numbers = list()
41 dataFile = open('numbers.txt', 'r')
42
43 for eachLine in dataFile:
44     #print eachLine
45     substrs = eachLine.split(',',eachLine.count(','))
46     #print substrs
47     for strVar in substrs:
48         if strVar.isdigit():
49             numbers.append(int(strVar))
50
51 print numbers
52 dataFile.close()
```

As you can see reading a text file from within python is a simple process. The first step is to open the file for reading, option r is used as the file is only going to be read, the other options are available in Table reftab:fileopenning. If the file is a text file then the contents can then be read a line at a time, if a binary file (e.g., tiff or doc) then reading is more complicated and not covered in this tutorial.

Table 3.1: Options when opening a file.

File Mode	Operations
r	Open for read
w	Open for write (truncate)
a	Open for write (append)
r+	Open for read/write
w+	Open for read/write (truncate)
a+	Open for read/write (append)
rb	Open for binary read
wb	Open for binary write (truncate)
ab	Open for binary write (append)
rb+	Open for read/write
wb+	Open for read/write (truncate)
ab+	Open for read/write (append)

Now your need to adapt the one of the methods given in the script above to allow numbers and words to be split into separate lists. To do this you will need to use the isalpha() function alongside the isdigit() function. Adapt the numbers.txt file to match the input shown below and then run your script and you should receive the output shown below:

Input:

```
1,
2,pete,
3,
4,dan,5,
6,7,8,richard,10,11,12,13
```

Output:

```
>python simplereadsplit.py
[1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 13]
['pete', 'dan', 'richard']
```

3.2 Write to a Text File

Writing to a text file is similar to reading from the file. When opening the file two choices are available either to append or truncate the file. Appending to the file leaves any content already within the file untouched while truncating the file removes any content already within the file. An example of writing a list to a file with each list item on a new line is given below.

```
#! /usr/bin/env python

########################################
# A simple script parsing numbers of
# words from a comma seperated text file
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
########################################

aList = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10,
'one', 'two', 'three', 'four', 'five',
'six', 'seven', 'eight', 'nine', 'ten']

dataFile = open('writetest.txt', 'w')

for eachitem in aList:
    dataFile.write(str(eachitem)+'\n')

dataFile.close()
```

3.3 Programming Styles

There are two main programming styles, both of which are supported by python, and these are procedural and object oriented programming. Procedural programming preceded object oriented programming and procedural scripts provide lists of commands which are run through sequentially.

Object oriented programming differs from procedural programming in that the program is split into a series of objects, usually representing really world objects or functionality, generally referred to as a 'class'. Objects support the concepts of inheritance where functionality can be used in many sub-objects. For example, a Person class maybe written with functions such as eat, drink, beat heart etc. and specialist sub-objects may then be created with Person as a super-object, for example child, adult, male and female. These objects all require the functionality of Person but it is inefficient to duplicate the functionality they share individual rather then group this functionality into the Person class.

This course will concentrate on basic object oriented programming but below are the basic python file outlines for both procedural and object oriented scripts.

3.3.1 Procedural Programming – File Outline

When creating a procedural python script each of your files will have the same basic format outlined below:

```
1  #! /usr/bin/env python
2
3  ########################################
4  # Comment explaining scripts purpose
5  # Author: <Author Name>
6  # Email: <Author's Email>
7  # Date: <Date Last Editor>
8  # Version: <Version Number>
9  ########################################
10
11 # IMPORTS
12 # e.g., import os
13
14 # SCRIPT
15 print "Hello World"
16
17 # End of File
```

3.3.2 Object Orientated Programming – File Outline

When creating an object oriented script each python file you create will have the same basic format outlined below:

```
#! /usr/bin/env python

########################################
# Comment explaining scripts purpose
# Author: <Author Name>
# Emai: <Author's Email>
# Date: <Date Last Editor>
# Version: <Version Number>
########################################

# IMPORTS
import os

# CLASS EXPRESSION - In this case class name is Person
class Person (object): # Object is the superclass

    # CLASS ATTRIBUTES
    name = ''

    # INITIALISE THE CLASS (OFTEN EMPTY)
    def __init__(self):
        self.name = 'Dan'

    # METHOD TO PRINT PERSON NAME
    def printName(self):
        print 'Name: ' + self.name

    # METHOD TO SET PERSON NAME
    def setName(self, inputName):
        self.name = inputName

    # METHOD TO GET PERSON NAME
    def getName(self):
        return self.name

```

```
36      # METHOD TO EXECUTE CLASS
37      def run(self):
38          self.printName()
39          self.setName('Pete')
40          self.printName()
41
42  # IF EXECUTED FROM THE COMMAND LINE
43  if __name__ == '__main__':
44      obj = Person()
45      obj.run()
46
47  # End of File
```

3.4 Object Oriented Script

For simple scripts like those demonstrated so far simple procedural scripts are all that have been required. When creating more complex scripts the introduction of more structured and reusable designs are preferable. To support this design Python supports object oriented program design.

3.4.1 Object Oriented Script for Text File Processing

To illustrate the difference in implementation an example is given and explained below. The example reads a comma separated text file (randfloats.txt) of random floating point numbers from which the mean and standard deviation is calculated. Create a new python script and copy the script below:

```
1  #! /usr/bin/env python
2
3  ########################################
4  # An python class to parse a comma
5  # separates text file to calculate
6  # the mean and standard deviation
7  # of the inputted floating point
8  # numbers.
```

```
9  # Author: <YOUR NAME>
10 # Email: <YOUR EMAIL>
11 # Date: DD/MM/YYYY
12 # Version: 1.0
13 ########################################
14
15 # import the squareroot function from python math
16 from math import sqrt
17
18 # Define a new class called CalcMeanStdDev
19 class CalcMeanStdDev (object):
20
21     # Define a function which parses a comma
22     # separated file - you should understand
23     # the contents of this script from the
24     # previous examples.
25     # Note: the file is passed into the
26     # function.
27     def parseCommaFile(self, file):
28         floatingNumbers = list()
29         for eachLine in file:
30             substrs = eachLine.split(',',eachLine.count(','))
31             for strVar in substrs:
32                 floatingNumbers.append(float(strVar))
33         return floatingNumbers
34
35     # Define a function to calculate the mean
36     # value from a list of numbers.
37     # Note. The list of numbers is passed into
38     # the function.
39     def calcMean(self, numbers):
40         # A variable to sum all the numbers
41         sum = 0.0
42         # Iterate through the numbers list
43         for number in numbers:
44             # add each number to the sum
45             sum += number
46         # Divide the sum by the number of
47         # values within the numbers list
48         # (i.e., its length)
49         mean = sum/len(numbers)
```

```
50          # return the mean value calculated
51          return mean
52
53      # Define a function which calculates the
54      # standard deviation of a list of numbers
55      # Note. The list of numbers is passed into
56      # the function alongside a previously
57      # calculated mean value for the list.
58      def calcStdDev(self, numbers, mean):
59          # Varible for total deviation
60          deviation = 0.0
61          # Variable for a single deviation
62          singleDev = 0.0
63          # Iterate through the list of numbers.
64          for number in numbers:
65              # Calculate a single Deviation
66              singleDev = number-mean
67              # Add the squared single deviation to
68              # to the on going total.
69              deviation += (singleDev**2)
70          # Calcate the standard devaition
71          stddev = sqrt(deviation/(len(numbers)-1))
72          # return the standard deviation
73          return stddev
74
75      # The main thread of processing. A function
76      # which defines the order of processing.
77      # Note. The filename is passed in.
78      def run(self, filename):
79          # Open the input file
80          inFile = open(filename, 'r')
81          # Parse the file to retrieve a list of
82          # numbers
83          numbers = self.parseCommaFile(inFile)
84
85          # Calculate the mean value of the list
86          mean = self.calcMean(numbers)
87          # Calculate the standard deviation of the
88          # list.
89          stddev = self.calcStdDev(numbers, mean)
90
```

```
91          # Print the results to screen
92          print 'Mean: ' + str(mean)
93          print 'Stddev: ' + str(stddev)
94
95          # Close the input file
96          inFile.close()
97
98  # When python is executed python executes
99  # the code with the lowest indentation first.
100 #
101 # We can identify when python is executed from
102 # the command line using the following if statment.
103 #
104 # When executed we want the run() function to be
105 # executed therefore we create a CalcMeanStdDev
106 # object and call run on that object - passing
107 # in the file name of the file to be processed.
108 if __name__ == '__main__':
109     obj = CalcMeanStdDev()
110     obj.run('randfloats.txt') # Update with full file path.
```

NOTE:

`__name__`

and

`__main__`

each have TWO underscores either side (i.e., _ _).

Although, an object oriented design has been introduced making the above code, potentially, more reusable the design does not separate more general functionality from the application. To do this the code will be split into two files the first, named MyMaths.py, will contain the mathematical operations calcMean and calcStdDev while the second, named FileSummary, contains the functions run, which controls the flow of the script, and parseCommaFile(). The code for these files is given below but first try and split the code into the two files yourself.

```
1  #! /usr/bin/env python
2
```

```
3  ########################################
4  # An python class to hold maths operations
5  # Author: <YOUR NAME>
6  # Email: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 from math import sqrt
12
13 class MyMathsClass (object):
14
15     def calcMean(self, numbers):
16         sum = 0.0
17         for number in numbers:
18             sum += number
19         mean = sum/len(numbers)
20         return mean
21
22     def calcStdDev(self, numbers, mean):
23         deviation = 0.0
24         singleDev = 0.0
25         for number in numbers:
26             singleDev = number-mean
27             deviation += (singleDev**2)
28         stddev = sqrt(deviation/(len(numbers)-1))
29         return stddev
30
31
```

```
1  #! /usr/bin/env python
2
3  ########################################
4  # An python class to parse a comma
5  # separates text file to calculate
6  # the mean and standard deviation
7  # of the inputted floating point
8  # numbers.
9  # Author: <YOUR NAME>
10 # Email: <YOUR EMAIL>
```

```
11 # Date: DD/MM/YYYY
12 # Version: 1.0
13 ########################################
14
15 # To import the class you have created
16 # you need to define the file within
17 # which the class is held. In this
18 # case MyMaths.py and the name of the
19 # class to be imported (i.e., MyMathsClass)
20 from MyMaths import MyMathsClass
21
22 class FileSummary (object):
23
24     def parseCommaFile(self, file):
25         floatingNumbers = list()
26         for eachLine in file:
27             substrs = eachLine.split(',',eachLine.count(','))
28             for strVar in substrs:
29                 floatingNumbers.append(float(strVar))
30         return floatingNumbers
31
32     def run(self, filename):
33         inFile = open(filename, 'r')
34         numbers = self.parseCommaFile(inFile)
35
36         mathsObj = MyMathsClass()
37         mean = mathsObj.calcMean(numbers)
38         stddev = mathsObj.calcStdDev(numbers, mean)
39
40         print 'Mean: ' + str(mean)
41         print 'Stddev: ' + str(stddev)
42
43
44 if __name__ == '__main__':
45     obj = FileSummary()
46     obj.run('randfloats.txt')
47
```

To allow the script to be used as a command line tool the path to the file needs be passed into the script at runtime therefore the following changes are made to

the FileSummary script:

```
#! /usr/bin/env python

########################################
# An python class to parse a comma
# separates text file to calculate
# the mean and standard deviation
# of the inputted floating point
# numbers.
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
########################################

from MyMaths import MyMathsClass
# To allow command line options to be
# retrieved the sys python library needs
# to be imported
import sys

class FileSummary (object):

    def parseCommaFile(self, file):
        floatingNumbers = list()
        for eachLine in file:
            substrs = eachLine.split(',',eachLine.count(','))
            for strVar in substrs:
                floatingNumbers.append(float(strVar))
        return floatingNumbers

    def run(self):
        # To retrieve the command line arguments
        # the sys.argv[X] is used where X refers to
        # the argument. The argument number starts
        # at 1 and is the index of a list.
        filename = sys.argv[1]
        inFile = open(filename, 'r')
        numbers = self.parseCommaFile(inFile)

```

```
40          mathsObj = MyMathsClass()
41          mean = mathsObj.calcMean(numbers)
42          stddev = mathsObj.calcStdDev(numbers, mean)
43
44          print 'Mean: ' + str(mean)
45          print 'Stddev: ' + str(stddev)
46
47  if __name__ == '__main__':
48      obj = FileSummary()
49      obj.run()
50
```

To read the new script the following command needs to be run from the command prompt:

```
python fileSummary_commandline.py randfloats.txt
```

3.5 Exercise

Calculate the mean and standard deviation from only the first column of data

Hint:

You will need to replace:

```
substrs = eachLine.split(',',eachLine.count(','))
for strVar in substrs:
    floatingNumbers.append(float(strVar))
```

With:

```
substrs = eachLine.split(',',eachLine.count(','))
# Select the column the data is stored in
column1 = substrs[0]
floatingNumbers.append(float(column1))
```

Chapter 4

File System – Finding files

4.1 Introduction

A common task for which python is used is to batch process a task or series of tasks. To do this the files to be processed need to be identified from within the file system. Therefore, in this tutorial you will learn to implement code to undertake this operation.

To start this type out the code below into a new file (save it as IterateFiles.py).

```
1  #! /usr/bin/env python
2
3  ########################################
4  # A class that iterates through a directory
5  # or directory structure and prints out theatre
6  # identified files.
7  # Author: <YOUR NAME>
8  # Email: <YOUR EMAIL>
9  # Date: DD/MM/YYYY
10 # Version: 1.0
11 ########################################
12
13 import os.path
14 import sys
15
```

```
16 class IterateFiles (object):
17
18     # A function which iterates through the directory
19     def findFiles(self, directory):
20         # check whether the current directory exits
21         if os.path.exists(directory):
22             # check whether the given directory is a directory
23             if os.path.isdir(directory):
24                 # list all the files within the directory
25                 dirFileList = os.listdir(directory)
26                 # Loop through the individual files within the directory
27                 for filename in dirFileList:
28                     # Check whether file is directory or file
29                     if(os.path.isdir(os.path.join(directory,filename))):
30                         print os.path.join(directory,filename) + \
31                         ' is a directory and therefore ignored!'
32                     elif(os.path.isfile(os.path.join(directory,filename))):
33                         print os.path.join(directory,filename)
34                     else:
35                         print filename + ' is NOT a file or directory!'
36             else:
37                 print directory + ' is not a directory!'
38         else:
39             print directory + ' does not exist!'
40
41
42
43     def run(self):
44         # Set the folder to search
45         searchFolder = './PythonCourse' # Update path...
46         self.findFiles(searchFolder)
47
48
49 if __name__ == '__main__':
50     obj = IterateFiles()
51     obj.run()
```

Using the online python documentation read through the section on the file system:

`http://docs.python.org/library/filesys.html`

http://docs.python.org/library/os.path.html

This documentation will allow you to understand the functionality which is available for manipulating the file system.

4.2 Recursion

The next stage is to add allow the function recursively go through the directory structure. To do this add the function below to your script above:

```
#! /usr/bin/env python

########################################
# A class that iterates through a directory
# or directory structure and prints out theatre
# identified files.
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
########################################

import os.path
import sys

class IterateFiles (object):

    # A function which iterates through the directory
    def findFilesRecurse(self, directory):
        # check whether the current directory exits
        if os.path.exists(directory):
            # check whether the given directory is a directory
            if os.path.isdir(directory):
                # list all the files within the directory
                dirFileList = os.listdir(directory)
                # Loop through the individual files within the directory
                for filename in dirFileList:
                    # Check whether file is directory or file
```

```
29                      if(os.path.isdir(os.path.join(directory,filename))):
30                          # If a directory is found recall this function.
31                          self.findFilesRecurse(os.path.join(directory,filename))
32                      elif(os.path.isfile(os.path.join(directory,filename))):
33                          print os.path.join(directory,filename)
34                      else:
35                          print filename + ' is NOT a file or directory!'
36              else:
37                  print directory + ' is not a directory!'
38          else:
39              print directory + ' does not exist!'
40
41      def run(self):
42          # Set the folder to search
43          searchFolder = './PythonCourse' # Update path...
44          self.findFilesRecurse(searchFolder)
45
46  if __name__ == '__main__':
47      obj = IterateFiles()
48      obj.run()
```

Now call this function instead of the findFiles. Think and observe what effect a function which calls itself will have on the order in which the file are found.

4.3 Checking file Extension

The next step is to include the function checkFileExtension to your class and create two new functions which only print out the files with the file extension of interest. This should be done for both the recursive and non-recursive functions above.

```
1  #! /usr/bin/env python
2
3  ########################################
4  # A class that iterates through a directory
5  # or directory structure and prints out theatre
6  # identified files.
```

```
7  # Author: <YOUR NAME>
8  # Email: <YOUR EMAIL>
9  # Date: DD/MM/YYYY
10 # Version: 1.0
11 ########################################
12
13 import os.path
14 import sys
15
16 class IterateFiles (object):
17
18     # A function which checks a file extension and returns
19     def checkFileExtension(self, filename, extension):
20         # Boolean variable to be returned by the function
21         foundExtension = False;
22         # Split the filename into two parts (name + ext)
23         filenamesplit = os.path.splitext(filename)
24         # Get the file extension into a varaiable
25         fileExtension = filenamesplit[1].strip()
26         # Decide whether extensions are equal
27         if(fileExtension == extension):
28             foundExtension = True
29         # Return result
30         return foundExtension
31
32     # A function which iterates through the directory and checks file extensions
33     def findFilesExtRecurse(self, directory, extension):
34         # check whether the current directory exits
35         if os.path.exists(directory):
36             # check whether the given directory is a directory
37             if os.path.isdir(directory):
38                 # list all the files within the directory
39                 dirFileList = os.listdir(directory)
40                 # Loop through the individual files within the directory
41                 for filename in dirFileList:
42                     # Check whether file is directory or file
43                     if(os.path.isdir(os.path.join(directory,filename))):
44                         # If a directory is found recall this function.
45                         self.findFilesRecurse(os.path.join(directory,filename))
46                     elif(os.path.isfile(os.path.join(directory,filename))):
47                         if(self.checkFileExtension(filename, extension)):
```

```
48                              print os.path.join(directory,filename)
49                      else:
50                          print filename + ' is NOT a file or directory!'
51              else:
52                  print directory + ' is not a directory!'
53          else:
54              print directory + ' does not exist!'
55
56
57      # A function which iterates through the directory and checks file extensions
58      def findFilesExt(self, directory, extension):
59          # check whether the current directory exits
60          if os.path.exists(directory):
61              # check whether the given directory is a directory
62              if os.path.isdir(directory):
63                  # list all the files within the directory
64                  dirFileList = os.listdir(directory)
65                  # Loop through the individual files within the directory
66                  for filename in dirFileList:
67                      # Check whether file is directory or file
68                      if(os.path.isdir(os.path.join(directory,filename))):
69                          print os.path.join(directory,filename) + \
70                          ' is a directory and therefore ignored!'
71                      elif(os.path.isfile(os.path.join(directory,filename))):
72                          if(self.checkFileExtension(filename, extension)):
73                              print os.path.join(directory,filename)
74                      else:
75                          print filename + ' is NOT a file or directory!'
76              else:
77                  print directory + ' is not a directory!'
78          else:
79              print directory + ' does not exist!'
80
81      def run(self):
82          # Set the folder to search
83          searchFolder = './PythonCourse' # Update path...
84          self.findFilesExt(searchFolder)
85
86  if __name__ == '__main__':
87      obj = IterateFiles()
88      obj.run()
```

4.4 Exercises

1. Rather than print the file paths to screen add them to a list and return them from the function. This would be useful for applications where the files to be process need to be known up front and creates a more generic piece of python which can be called from other scripts.
2. Using the return list add code to loop through the returned list and print out the file information in the following comma separated format.

```
[FILE NAME], [EXTENSION], [PATH], [DRIVE LETTER (On Windows)], [MODIFICATION TIME]
```

Chapter 5

Plotting - Matplotlib

5.1 Introduction

Many open source libraries are available from within python. These significantly increase the available functionality, decreasing your development time. One such library is matplotlib (`http://matplotlib.sourceforge.net`), which provides a plotting library with a similar interface to those available within Matlab. The matplotlib website provides a detailed tutorial and documentation for all the different options available within the library but this worksheet provides some examples of the common plot types and a more complex example continuing on from previous examples.

5.2 Simple Script

Below is your first script using the matplotlib library. The script demonstrates the plotting of a mathematical function, in this case a sine function. The plot function requires two lists of numbers to be provided, which provides the x and y locations of the points which go to create the displayed function. The axis can be labelled using the xlabel() and ylabel() functions while the title is set using the title() function. Finally, the show() function is used to reveal the interface

displaying the plot.

```
#! /usr/bin/env python

########################################
# A simple python script to display a
# sine function
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
########################################

# import the matplotlib libraries
from pylab import *

# Create a list with values from
# 0 to 3 with 0.01 intervals
t = arange(0.0, 3, 0.01)
# Calculate the sin curve for
# the values within t
s = sin(pi*t)

# Plot the values in s and t
plot(t, s)
xlabel('X Axis')
ylabel('Y Axis')
title('Simple Plot')
# save plot to disk.
savefig('simpleplot.pdf', dpi=200, format='PDF')
```

5.3 Bar Chart

The creation of a bar chart is equally simply where two lists are provided, the first contains the locations on the X axis at which the bars start and the second the heights of the bars. The width of the bars can also be specified and their colour. More options are available in the documentation (`http://matplotlib.`

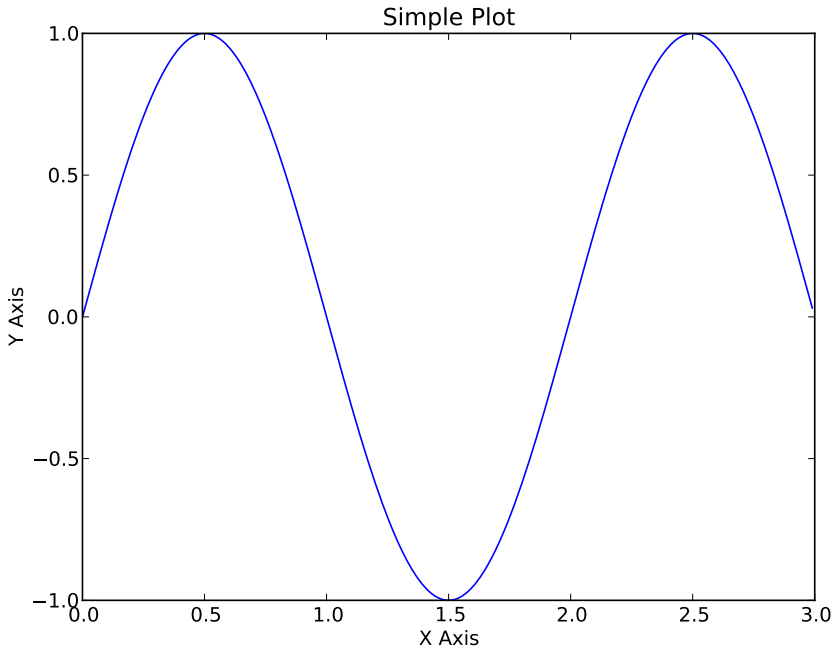

Figure 5.1: A simple plot using matplotlib.

sourceforge.net/matplotlib.pylab.html#-bar)

```
#! /usr/bin/env python

########################################
# A simple python script to display a
# bar chart.
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
########################################

from pylab import *

# Values for the Y axis (i.e., height of bars)
height = [5, 6, 7, 8, 12, 13, 9, 5, 7, 4, 3, 1]
# Values for the x axis
x = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
```

```
18
19 # create plot with colour grey
20 bar(x, height, width=1, color='gray')
21 # save plot to disk.
22 savefig('simplebar.pdf', dpi=200, format='PDF')
```

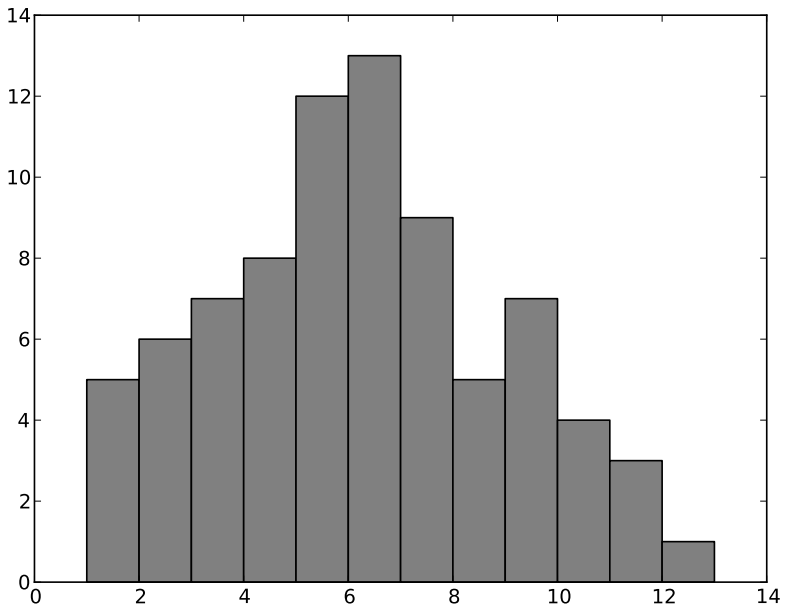

Figure 5.2: A simple bar chart using matplotlib.

5.4 Pie Chart

A pie chart is similar to the previous scripts where a list of the fractions making up the pie chart is given alongside a list of labels and if required a list of fractions to explode the pie chart. Other options including colour and shadow are available and outlined in the documentation (`http://matplotlib.sourceforge.net/matplotlib.pylab.html#-pie`) This script also demonstrates the use of the savefig() function allowing the plot to be saved to file rather than simply displayed on screen.

```
#! /usr/bin/env python

########################################
# A simple python script to display a
# pie chart.
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
########################################

from pylab import *

frac = [25, 33, 17, 10, 15]
labels = ['25', '33', '17', '10', '15']
explode = [0, 0.25, 0, 0, 0]

# Create pie chart
pie(frac, explode, labels, shadow=True)
# Give it a title
title('A Sample Pie Chart')
# save the plot to a PDF file
savefig('pichart.pdf', dpi=200, format='PDF')
```

5.5 Scatter Plot

The following script demonstrates the production of a scatter plot (`http://matplotlib.sourceforge.net/matplotlib.pylab.html#-scatter`) where the lists x and y provide the locations of the points in the X and Y axis and Z provides the third dimension used to colour the points.

```
#! /usr/bin/env python

########################################
# A simple python script to display a
# scatter plot.
# Author: <YOUR NAME>
```

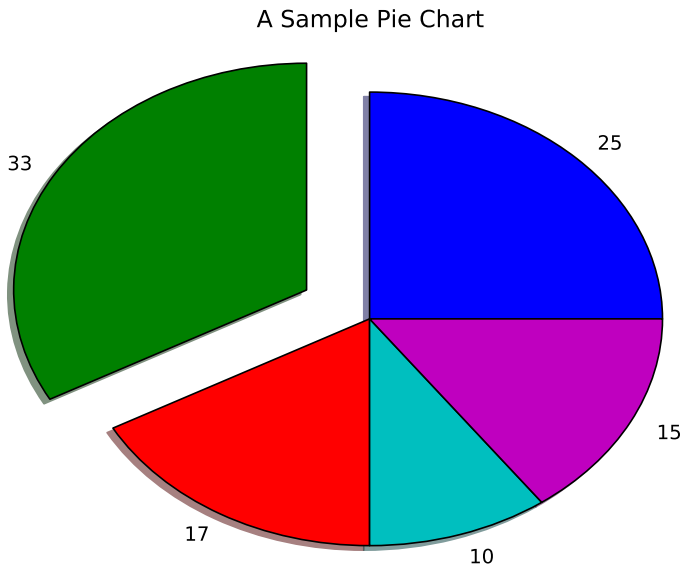

Figure 5.3: A simple pie chart using matplotlib.

```
7  # Email: <YOUR EMAIL>
8  # Date: DD/MM/YYYY
9  # Version: 1.0
10 ########################################
11
12 from pylab import *
13 # Import a random number generator
14 from random import random
15
16 x = []
17 y = []
18 z = []
19
20 # Create data values for X, Y, Z axis'
21 for i in range(5000):
22     x.append(random() * 100)
23     y.append(random() * 100)
24     z.append(x[i]-y[i])
25
```

```
26 # Create figure
27 figure()
28 # Create scatter plot where the plots are coloured using the
29 # Z values.
30 scatter(x, y, c=z, marker='o', cmap=cm.jet, vmin=-100, vmax=100)
31 # Display colour bar
32 colorbar()
33 # Make axis' tight to the data
34 axis('tight')
35 xlabel('X Axis')
36 ylabel('Y Axis')
37 title('Simple Scatter Plot')
38 # save plot to disk.
39 savefig('simplescatter.pdf', dpi=200, format='PDF')
```

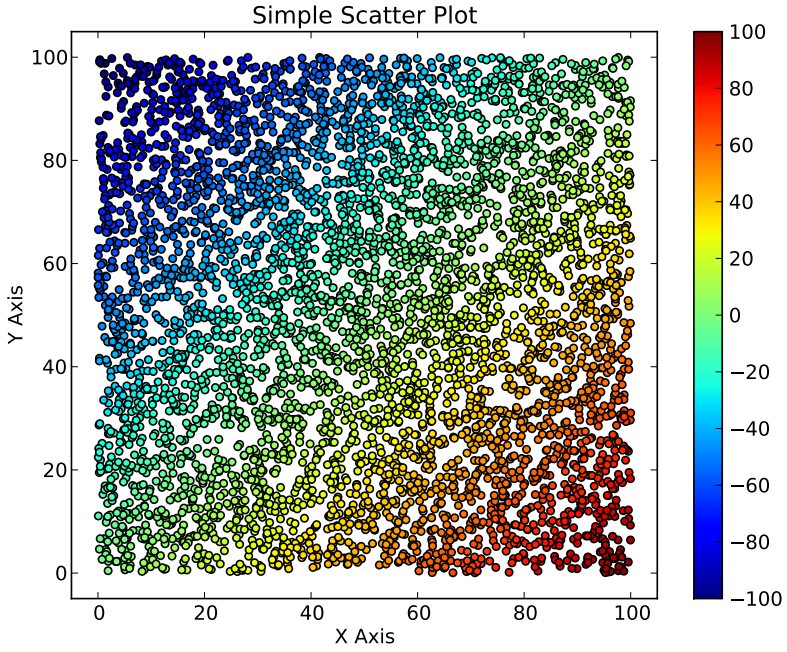

Figure 5.4: A simple scatter plot using matplotlib.

5.6 Line Plot

A more complicated example is now given building on the previous tutorial where the data is read in from a text file before being plotted. In this case data was downloaded from the Environment Agency and converted from columns to rows. The dataset provides the five year average rainfall for the summer (June - August) and winter (December - February) from 1766 to 2006. Two examples of plotting this data are given where the first plots the two datasets onto the same axis (Figure 5.5) while the second plots them onto individual axis (Figure 5.6). Information on the use of the subplot() function can be found in the matplotlib documentation (`http://matplotlib.sourceforge.net/matplotlib.pylab.html#-subplot`).

```
1  ########################################
2  # A python script to read in a text file
3  # of rainfall data for summer and winter
4  # within the UK and display as a plot.
5  # Author: <YOUR NAME>
6  # Email: <YOUR EMAIL>
7  # Date: DD/MM/YYYY
8  # Version: 1.0
9  ########################################
10
11 from pylab import *
12 import os.path
13 import sys
14
15 class PlotRainfall (object):
16
17     # Parse the input file - Three columns year, summer, winter
18     def parseDataFile(self, dataFile, year, summer, winter):
19         line = 0
20         for eachLine in dataFile:
21             commaSplit = eachLine.split(',', eachLine.count(','))
22             first = True
23             for token in commaSplit:
24                 if first:
25                     first = False
26                 else:
```

```
27                      if line == 0:
28                          year.append(int(token))
29                      elif line == 1:
30                          summer.append(float(token))
31                      elif line == 2:
32                          winter.append(float(token))
33              line += 1
34
35      # Plot data onto the same axis'
36      def plotData(self, year, summer, winter, outFile):
37          figure()
38          plot(year, summer)
39          plot(year, winter)
40          legend(['Summer', 'Winter'])
41          xlabel('Year')
42          ylabel('Rainfall (5 Year Mean)')
43          title('Summer and Winter rainfall across the UK')
44          # save plot to disk.
45          savefig(outFile, dpi=200, format='PDF')
46
47      # Plot the data onto separate axis, using subplot.
48      def plotDataSeparate(self, year, summer, winter, outFile):
49          figure()
50          subplot(2,1,1)
51          plot(year, summer)
52          ylabel('Rainfall (5 Year Mean)')
53          title('Summer rainfall across the UK')
54          axis('tight')
55
56          subplot(2,1,2)
57          plot(year, winter)
58          xlabel('Year')
59          ylabel('Rainfall (5 Year Mean)')
60          title('Winter rainfall across the UK')
61          axis('tight')
62          # save plot to disk.
63          savefig(outFile, dpi=200, format='PDF')
64
65      def run(self):
66          filename = 'ukweatheraverage.csv'
67          if os.path.exists(filename):
```

```
68              year = list()
69              summer = list()
70              winter = list()
71              try:
72                  dataFile = open(filename, 'r')
73              except IOError, e:
74                  print '\nCould not open file:\n', e
75                  return
76              self.parseDataFile(dataFile, year, summer, winter)
77              dataFile.close()
78              self.plotData(year, summer, winter, "Rainfall_SinglePlot.pdf")
79              self.plotDataSeparate(year, summer, winter, "Rainfall_MultiplePlots.pdf")
80          else:
81              print 'File \'' + filename + '\' does not exist.'
82
83  if __name__ == '__main__':
84      obj = PlotRainfall()
85      obj.run()
```

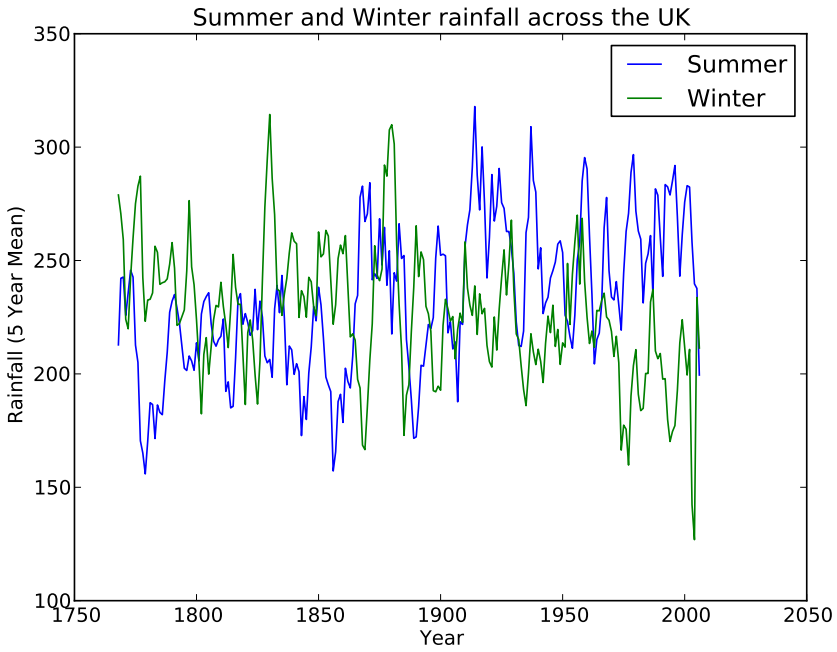

Figure 5.5: Rainfall data for summer and winter on the same axis'.

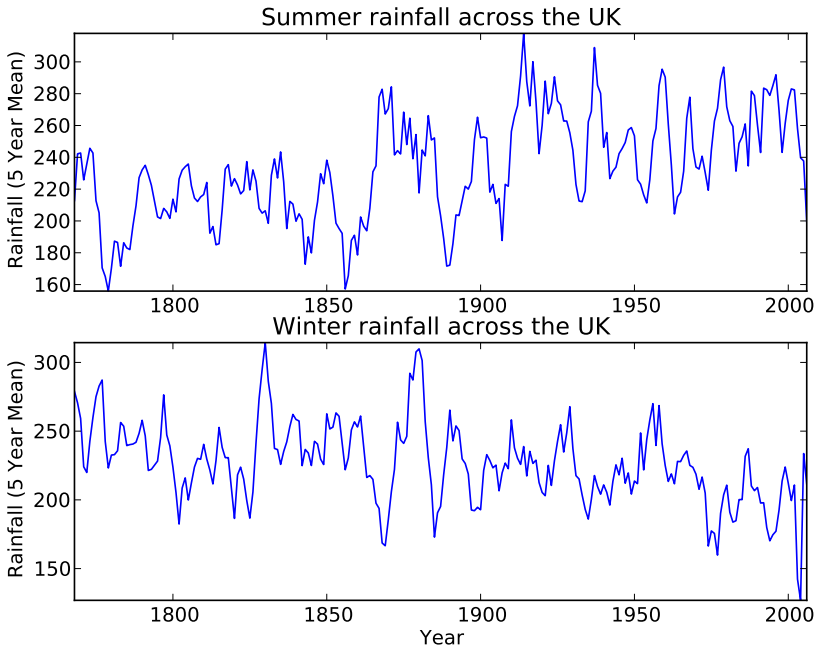

Figure 5.6: Rainfall data for summer and winter on different axis'.

5.7 Exercise:

Based on the available data is there a correlation between summer and winter rainfall? Use the lists read in of summer and winter rainfall and produce a scatterplot to answer this question.

Chapter 6

Statistics (SciPy / NumPy)

6.1 Introduction

NumPy is a library for storing and manipulating multi-dimensional arrays. NumPy arrays are similar to lists, however they have a lot more functionality and allow faster operations. SciPy is a library for maths and science using NumPy arrays and includes routines for statistics, optimisation and numerical integration. A comprehensive list is available from the SciPy website (`http://docs.scipy.org/doc/scipy/reference`). The combination of NumPy, SciPy and MatPlotLib provides similar functionality to that available in packages such as MatLab and Mathematica and allows for complex numerical analysis.

This tutorial will introduce some of the statistical functionality of NumPy / SciPy by calculating statistics from forest inventory data, read in from a text file. Linear regression will also be used to calculate derive relationships between parameters.

There are a number of ways to create NumPy arrays, one of the easiest (and the method that will be used in this tutorial) is to convert a python list to an array:

```
import numpy as np
pythonList = [1 , 4 , 2 , 5, 3]
numpyArray = np.array(pythonList)
```

6.2 Simple Statistics

Forest inventory data have been collected for a number of plots within Penglais woods (Aberystwyth, Wales). For each tree, the diameter, species height, crown size and position have been recorded. An example script is provided to read the diameters into a separate list for each species. The lists are then converted to NumPy arrays, from which statistics are calculated and written out to a text file.

```
#! /usr/bin/env python

########################################
# A script to calculate statistics from
# a text file using NumPy
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY

import numpy as np
import scipy as sp
# Import scipy stats functions we need
from scipy.stats import skew

class CalculateStatistics (object):

    def run(self):
        # Set up lists to hold input diameters
        # A seperate list is used for each species
        beechDiameter = list()
        ashDiameter = list()
        birchDiameter = list()
        oakDiameter = list()
        sycamoreDiameter = list()
        otherDiameter = list()

        # Open input and output files
        inFileName = 'PenglaisWoodsData.csv'
```

```
31          outFileName = 'PenglaisWoodsStats.csv'
32          inFile = open(inFileName, 'r')
33          outFile = open(outFileName,'w')
34
35          # Iterate through the input file and save diameter into
36          # lists, based on species
37          header = True
38          for eachLine in inFile:
39              if header: # Skip header row
40                  print 'Skipping header row'
41                  header = False
42              else:
43                  substrs = eachLine.split(',',eachLine.count(','))
44
45                  species = substrs[3]
46                  if substrs[4].isdigit: # Check diameter is a number
47                      diameter = float(substrs[4])
48
49                      if species == 'BEECH':
50                          beechDiameter.append(diameter)
51                      elif species == 'ASH':
52                          ashDiameter.append(diameter)
53                      elif species == 'BIRCH':
54                          birchDiameter.append(diameter)
55                      elif species == 'OAK':
56                          oakDiameter.append(diameter)
57                      elif species == 'SYC':
58                          sycamoreDiameter.append(diameter)
59                      else:
60                          otherDiameter.append(diameter)
61
62          # Convert input lists to NumPy arrays
63          beechDiameter = np.array(beechDiameter)
64          ashDiameter = np.array(ashDiameter)
65          birchDiameter = np.array(birchDiameter)
66          oakDiameter = np.array(oakDiameter)
67          sycamoreDiameter = np.array(sycamoreDiameter)
68          otherDiameter = np.array(otherDiameter)
69
70          # Write header line to output file
71          headerLine = 'species, meanDiameter, medianDiameter, stDevDiameter\n'
```

```
72          outFile.write(headerLine)
73
74          # Calculate statistics for each species and write to file
75          outLine = 'Beech,' + self.createStatsLine(beechDiameter) + '\n'
76          outFile.write(outLine)
77          outLine = 'Ash,' + self.createStatsLine(ashDiameter) + '\n'
78          outFile.write(outLine)
79          outLine = 'Birch,' + self.createStatsLine(birchDiameter) + '\n'
80          outFile.write(outLine)
81          outLine = 'Oak,' + self.createStatsLine(oakDiameter) + '\n'
82          outFile.write(outLine)
83          outLine = 'Sycamore,' + self.createStatsLine(sycamoreDiameter) + '\n'
84          outFile.write(outLine)
85          outLine = 'Other,' + self.createStatsLine(otherDiameter) + '\n'
86          outFile.write(outLine)
87
88          print 'Statistics written to: ' + outFileName
89
90
91      def createStatsLine(self, inArray):
92          # Calculate statsistics for NumPy array and return output line.
93          meanArray = np.mean(inArray)
94          medianArray = np.median(inArray)
95          stDevArray = np.std(inArray)
96          skewArray = skew(inArray)
97
98          # Create output line with stats
99          statsLine = str(meanArray) + ',' + str(medianArray) + ',' + str(stDevArray)
100         return statsLine
101
102 if __name__ == '__main__':
103     obj = CalculateStatistics()
104     obj.run()
```

Note in tutorial three, functions were written to calculate the mean and standard deviation a list, in this tutorial the same result is accomplished using the built in functionality of NumPy.

6.2.1 Exercises

1. Based on the example script also calculate mean, median and standard deviation for tree heights and add to the output file.
2. Look at other statistics functions available in SciPy and calculate for height and density.

6.3 Calculate Biomass

One of the features of NumPy arrays is the ability to perform mathematical operation on all elements of an array.

For example, for NumPy array a:

```
a = np.array([1,2,3,4])
```

Performing

```
b = 2 * a
```

Gives

```
b = array([2,4,6,8])
```

Some special versions of functions are available to work on arrays. To calculate the natural log of a single number log may be used, to perform the natural log of an array np.log may be used (where NumPy has been imported as np).

Tree volume may be calculated from height and stem diameter using:

$$\text{Volume} = a + bD^2h^{0.75} \tag{6.1}$$

Where D is diameter and h is height. The coefficients a and b vary according to species (see Table 6.1). From volume, it is possible to calculate biomass by multiplying by the specific gravity.

$$\text{Biomass} = \text{Volume} \times \text{SpecificGravity} \tag{6.2}$$

The specific gravity also varies by species, values for each species are given in Table 6.1.

Table 6.1: Coefficients for estimating volume and the specific gravity required for estimating the biomass by species.

Species	a-coefficient	b-coefficient	Specific gravity
Beech	0.014306	0.0000748	0.56
Ash	0.012107	0.0000777	0.54
Beech	0.009184	0.0000673	0.53
Oak	0.011724	0.0000765	0.56
Sycamore	0.012668	0.0000737	0.54

The following function takes two arrays containing height and density, and a string for species. From these biomass is calculated.

```
1  def calcBiomass(self, inDiameterArray, inHeightArray, inSpecies):
2          if inSpecies == 'BEECH':
3              a = 0.014306
4              b = 0.0000748
5              specificGravity = 0.56
6
7          # Calculate Volume
8          volume = a + ((b*(inDiameterArray / 100)**2) * (inHeightArray**0.75))
9          # Calculate biomass
10         biomass = volume * specificGravity
11         # Return biomass
12         return biomass
```

Note only the coefficients for 'BEECH' have been included therefore, if a different species is passed in, the program will produce an error (try to think about what the error would be). A neater way of dealing with the error would be to throw an exception if the species was not recognised. Exceptions form the basis of controlling errors in a number of programming languages (including C++ and Java) the simple concept is that as a program is running, if an error occurs an exception is thrown, at which point processing stops until the exception is caught and dealt with. If the

exception is never caught, then the software crashes and stops. Python provides the following syntax for exception programming,

```
try:
    < Perform operations during which
     an error is likely to occur >
except <ExceptionName>:
   < If error occurs do something
     appropriate >
```

where the code you wish to run is written inside the 'try' statement and the 'except' statement is executed only when a named exception (within the except statement) is produced within the 'try' block. It is good practise you use exceptions where possible as when used properly they provide more robust code which can provide more feedback to the user.

The function to calculate biomass may be rewritten to throw an exception if the species is not recognised.

```
1  def calcBiomass(self, inDiameterArray, inHeightArray, inSpecies):
2          if inSpecies == 'BEECH':
3              a = 0.014306
4              b = 0.0000748
5              specificGravity = 0.56
6          else: # Raise exception if species is not recognised
7              raise Exception('Species not recognised')
8
9          # Calculate Volume
10         volume = a + ((b*(inDiameterArray / 100)**2) * (inHeightArray**0.75))
11         # Calculate biomass
12         biomass = volume * specificGravity
13         # Return biomass
14         return biomass
```

The function below, calls 'calcBiomass' to calculate biomass for an array. From this mean, median and standard deviation are calculated and an output array is returned. By calling the function from within a 'try and except' block if the species is not recognised, it will not try to calculate stats and will return the string 'na' (not available) for all values in the output line.

```
def calcBiomassStatsLine(self, inDiameterArray, inHeightArray, inSpecies):
        # Calculates biomass, calculates stats from biomass and returns output line
        biomassStatsLine = ''
        try:
            # Calculate biomass
            biomass = self.calcBiomass(inDiameterArray, inHeightArray, inSpecies)
            # Calculate stats from biomass
            meanBiomass = np.mean(biomass)
            medianBiomass = np.median(biomass)
            stDevBiomass = np.std(biomass)

            # Create output line
            biomassStatsLine = str(meanBiomass) + ',' + str(medianBiomass) + ',' + \
str(stDevBiomass)

        except Exception:
            # Catch exception and write 'na' for all values
            biomassStatsLine = 'na,na,na'

        return biomassStatsLine
```

Therefore, the final script should result in the following:

```
#! /usr/bin/env python

########################################
# A script to calculate statistics from
# a text file using NumPy
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY

153         return biomassStatsLine
154 
155     def calcBiomass(self, inDiameterArray, inHeightArray, inSpecies):
156         if inSpecies == 'BEECH':
157             a = 0.014306
158             b = 0.0000748
159             specificGravity = 0.56
160         else: # Raise exception is species is not recognised
161             raise Exception('Species not recognised')
162 
163         # Calcualte volume
164         volume = a + ((b*(inDiameterArray)**2) * (inHeightArray**0.75))
165         # Calculate biomass
166         biomass = volume * specificGravity
167         # Return biomass
168         return biomass
169 
170 if __name__ == '__main__':
171     obj = CalculateStatistics()
172     obj.run()
```

6.3.1 Exercise

1. Add in the coefficients to calculate biomass for the other species
2. Write the statistics for biomass out to the text file. Remember to change the header line.

6.4 Linear Fitting

One of the built in feature of SciPy is the ability to perform fits. Using the linear regression function (linregress) it is possible to fit equations of the form:

$$y = ax + b \tag{6.3}$$

to two NumPy arrays (x and y) using:

```
(aCoeff,bCoeff,rVal,pVal,stdError) = linregress(x, y)
```

Where aCoeff and bCoeff are the coefficients rVal is the r value (r**2 gives R^2), pVal is the p value and stdError is the standard error.

It is possible to fit the following equation to the collected data expressing height as a function of diameter.

$$\text{height} = a \log(\text{diameter}) + b \tag{6.4}$$

To fit an equation of this form an array must be created containing log diameter . Linear regression may then be performed using:

```
linregress(np.log(inDiameterArray), inHeightArray)
```

To test the fit it may be plotted against the original data using MatPlotLib. The following code first performs the linear regression then creates a plot showing the fit against the original data.

```
1  def plotLinearRegression(self, inDiameterArray, inHeightArray, outPlotName):
2          # Perform fit
3          (aCoeff,bCoeff,rVal,pVal,stdError) = linregress(np.log(inDiameterArray), \
4                                                          inHeightArray)
5
6          # Use fits to predict height for a range of diameters
7          testDiameter = arange(min(inDiameterArray), max(inDiameterArray), 1)
8          predictHeight = (aCoeff * np.log(testDiameter)) + bCoeff
9
10         # Create a string, showing the form of the equation (with fitted coefficients)
```

```
        # and r squared value
        # Coefficients are rounded to two decimal places.
        equation = str(round(aCoeff,2)) + 'log(D) + ' + str(round(bCoeff,2)) + \
                   ' (r$^2$ = ' + str(round(rVal**2,2)) + ')'

        # Plot fit against origional data
        plot(inDiameterArray, inHeightArray,'.')
        plot(testDiameter, predictHeight)
        xlabel('Diameter (cm)')
        ylabel('Height (m)')
        legend(['measured data',equation])

        # Save plot
        savefig(outPlotName, dpi=200, format='PDF')
```

The coefficients and r^2 of the fit are displayed in the legend. To display the superscript '2' in the data it is possible to use LaTeX syntax. So r^2 is written as: r$\wedge$2$.

The function may be called using:

```
# Set output directory for plots
outDIR = './output/directory/'

self.plotLinearRegression(beechDiameter, beechHeight, outDIR + 'beech.pdf')
```

Produce a plot similar to the one shown in Figure 6.1 and save as a PDF.

The final script should result in the following:

```
#! /usr/bin/env python

########################################
# A script to calculate statistics from
# a text file using NumPy
# Author: <YOUR NAME>
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY

Chapter 7

Batch Processing Command Line Tools

7.1 Introduction

There are many command line tools and utilities available for all platforms (e.g., Windows, Linux, Mac OSX), these tools are extremely useful and range from simple tasks such as renaming a file to more complex tasks such as merging ESRI shapefiles. One problem with these tools is that if you have a large number of files, which need to be processed in the same way, it is time consuming and error prone to manual run the command for each file. Therefore, if we can write scripts to do this work for us then processing large number of individual files becomes a much simpler and quicker task.

For this worksheet you will need to have the command line tools which come with the GDAL/OGR (`http://www.gdal.org`) open source software library installed and available with your path. With the installation of python(x,y) the python libraries for GDAL/OGR have been installed but not the command line utilities which go along with these libraries. If you do not already have them installed therefore details on the GDAL website for your respective platform.

7.2 Merging ESRI Shapefiles

The first example illustrates how the 'ogr2ogr' command can be used to merge shapefiles and a how a python script can be used to turn this command into a batch process where a whole directory of shapefiles can be merged.

To perform this operation two commands are required. The first makes a copy of the first shapefile within the list of files into a new file, shown below:

```
> ogr2ogr <inputfile> <outputfile>
```

While the second command appends the contents of the inputted shapefile onto the end of an existing shapefile (i.e., the one just copied).

```
> ogr2ogr -update -append <inputfile> <outputfile> -nln <outputfilename>
```

For both these commands the shapefiles all need to be of the same type (point, polyline or polygon) and contain the same attributes. Therefore, your first exercise is to understand the use of the ogr2ogr command and try them from the command line with the data provided. *Hint*, running ogr2ogr without any options the help file will be displayed.

The second stage is to develop a python script to call the appropriate commands to perform the required operation, where the following processes will be required:

1. Get the user inputs.
2. List the contents of the input directory.
3. Iterate through the directory and run the required commands.

But the first step is to create the class structure in which the code will fit, this will be something similar to that shown below:

```
1 #! /usr/bin/env python
2
3 ########################################
4 # MergeSHPfiles.py
5 # A python script to merge shapefiles
6 # Author: <YOUR NAME>
```

```
# Email: <YOUR EMAIL>
# Date: DD/MM/YYYY
# Version: 1.0
#########################################

import os

class MergeSHPfiles (object):

    # A function which controls the rest of the script
    def run(self):
        # Define the input directory
        filePath = './TreeCrowns/'
        # Define the output file
        newSHPfile = 'Merged_shapefile.shp'

# The start of the code
if __name__ == '__main__':
    # Make an instance of the class
    obj = MergeSHPfiles()
    # Call the function run()
    obj.run()
```

The script will have the input directory and output file hard coded (as shown) within the run function. Therefore, you need to edit these file paths to the location you have the files saved. Please note that under Windows you need to insert a double slash (i.e.,
) within the file path as a single slash is an escape character (e.g.,
n for new line) within strings.

The next step is to check that the input directory exists and is a directory, to do this edit your run function as below.

```
# A function which controls the rest of the script
def run(self):
    # Define the input directory
    filePath = './TreeCrowns/'
    # Define the output file
    newSHPfile = 'Merged_shapefile.shp'
```

```
7
8       # Check input file path exists and is a directory
9       if not os.path.exists(filePath):
10          print 'Filepath does not exist'
11      elif not os.path.isdir(filePath):
12          print 'Filepath is not a directory!'
13      else:
14          # Merge the shapefiles within the filePath
15          self.mergeSHPfiles(filePath, newSHPfile)
```

Additionally, you need to add the function mergeSHPFiles, which is where the shapefiles will be merged.

```
# A function to control the merging of shapefiles
def mergeSHPfiles(self, filePath, newSHPfile):
```

To merge the shapefiles the first task is to get a list of all the shapefiles within a directory. To do this, use the code you developed in Tutorial 4 to list files within a directory and edit it such that the files are outputted to a list rather than printed to screen, as shown below.

```
1   # A function to test the file extension of a file
2   def checkFileExtension(self, filename, extension):
3       # Boolean variable to be returned by the function
4       foundExtension = False;
5       # Split the filename into two parts (name + ext)
6       filenamesplit = os.path.splitext(filename)
7       # Get the file extension into a varaiable
8       fileExtension = filenamesplit[1].strip()
9       # Decide whether extensions are equal
10      if(fileExtension == extension):
11          foundExtension = True
12      # Return result
13      return foundExtension
14
15
16  # A function which iterates through the directory and checks file extensions
17  def findFilesExt(self, directory, extension):
18      # Define a list to store output list of files
19      fileList = list()
20      # check whether the current directory exits
```

```
21      if os.path.exists(directory):
22          # check whether the given directory is a directory
23          if os.path.isdir(directory):
24              # list all the files within the directory
25              dirFileList = os.listdir(directory)
26              # Loop through the individual files within the directory
27              for filename in dirFileList:
28                  # Check whether file is directory or file
29                  if(os.path.isdir(os.path.join(directory,filename))):
30                      print os.path.join(directory,filename) + \
31                      ' is a directory and therefore ignored!'
32                  elif(os.path.isfile(os.path.join(directory,filename))):
33                      if(self.checkFileExtension(filename, extension)):
34                          fileList.append(os.path.join(directory,filename))
35                  else:
36                      print filename + ' is NOT a file or directory!'
37          else:
38              print directory + ' is not a directory!'
39      else:
40          print directory + ' does not exist!'
41      # Return the list of files
42      return fileList
```

Note, that you also need the function to check the file extension.

This can then be added to the mergeSHPfiles function with a list to iterate through the identified files.

```
1  # A function to control the merging of shapefiles
2  def mergeSHPfiles(self, filePath, newSHPfile):
3      # Get the list of files within the directory
4      # provided with the extension .shp
5      fileList = self.findFilesExt(filePath, '.shp')
6      # Iterate through the files.
7      for file in fileList:
8          print file
```

When iterating through the files the ogr2ogr commands to be executed to merge the shapefiles need to be built and executed therefore the following code needs to be added to your script.

```
# A function to control the merging of shapefiles
def mergeSHPfiles(self, filePath, newSHPfile):
    # Get the list of files within the directory
    # provided with the extension .shp
    fileList = self.findFilesExt(filePath, '.shp')
    # Variable used to identify the first file
    first = True
    # A string for the command to be built
    command = ''
    # Iterate through the files.
    for file in fileList:
        if first:
            # If the first file make a copy to create the output file
            command = 'ogr2ogr ' + newSHPfile + ' ' + file
            first = False
        else:
            # Otherwise append the current shapefile to the output file
            command = 'ogr2ogr -update -append ' + newSHPfile + ' '  + \
            file + ' -nln ' + \
            self.removeSHPExtension(self.removeFilePathUNIX(newSHPfile))
        # Execute the current command
        os.system(command)
```

You also require the additional functions to remove the shapefile extension (.shp) and the windows file path, creating the layer name which are given below.

```
# A function to remove a .shp extension from a file name
def removeSHPExtension(self, name):
    # The output file name
    outName = name
    # Find how many '.shp' strings are in the current file
    # name
    count = name.find('.shp', 0, len(name))
    # If there are no instances of .shp then -1 will be returned
    if not count == -1:
        # Replace all instances of .shp with empty string.
        outName = name.replace('.shp', '', name.count('.shp'))
    # Return output file name without .shp
    return outName
```

```
14
15  # A function to remove the file path a file
16  # (in this case a windows file path)
17  def removeFilePathWINS(self, name):
18      # Remove white space (i.e., spaces, tabs)
19      name = name.strip()
20      # Count the number of slashs
21      # A double slash is required because \ is a
22      # string escape charater.
23      count = name.count('\\')
24      # Split string into a list where slashs occurs
25      nameSegments = name.split('\\', count)
26      # Return the last item in the list
27      return nameSegments[count]
28
29  # A function to remove the file path a file
30  def removeFilePathUNIX(self, name):
31      # Remove white space (i.e., spaces, tabs)
32      name = name.strip()
33      # Count the number of slashs
34      count = name.count('/')
35      # Split string into a list where slashs occurs
36      nameSegments = name.split('/', count)
37      # Return the last item in the list
38      return nameSegments[count]
```

If you wanted to use this script on UNIX (i.e., Linux or Mac OS X) you would need to use the removeFilePathUNIX as shown while for windows change the code to use the removeFilePathWINS function such that the double escaped slashes are used.

You script should now be complete so execute it on the data provided, within the TreeCrowns directory. Take time to understand the lines of code which have been provided and make sure your script works.

133         else:
134             # Merge the shapefiles within the filePath
135             self.mergeSHPfiles(filePath, newSHPfile)
136 
137 # The start of the code
138 if __name__ == '__main__':
139     # Make an instance of the class
140     obj = MergeSHPfiles()
141     # Call the function run()
142     obj.run()
```

7.3 Convert Images to GeoTIFF using GDAL.

The next example will require you to use the script developed above as the basis for a new script using the command below to convert a directory of images to GeoTIFF using the command given:

```
gdal_translate -of <OutputFormat> <InputFile> <OutputFile>
```

A useful step is to first run the command from the command line manually to make sure you understand how this command is working.

The two main things you need to think about are:

1. What file extension will the input files have? This should be user selectable alongside the file paths.
2. What output file name should be provided? The script should generate this.

Four test images have been provided in ENVI format within the directory ENVI_Images, you can use these for testing your script. If you are struggling then an example script with a solution to this task has been provided within the code directory.

7.3.1 Passing Inputs from the Command Line into your script

It is often convenient to provide the inputs the scripts requires (e.g., input and output file locations) as arguments to the script rather than needing to the edit the script each time a different set of parameters are required (i.e., changing the files paths in the scripts above). This is easy within python and just requires the following changes to your run function (in this case for the merge shapefiles script).

```
# A function which controls the rest of the script
def run(self):
    # Get the number of arguments
    numArgs = len(sys.argv)
    # Check there are only 2 input argument (i.e., the input file
    # and output base).
    # Note that argument 0 (i.e., sys.argv[0]) is the name
    # of the script currently running.
    if numArgs == 3:
        # Retrieve the input directory
        filePath = sys.argv[1]
        # Retrieve the output file
        newSHPfile = sys.argv[2]

        # Check input file path exists and is a directory
        if not os.path.exists(filePath):
            print 'Filepath does not exist'
        elif not os.path.isdir(filePath):
            print 'Filepath is not a directory!'
        else:
            # Merge the shapefiles within the filePath
            self.mergeSHPfiles(filePath, newSHPfile)
    else:
        print "ERROR. Command should have the form:"
        print "python MergeSHPfiles_cmd.py <Input File Path> <Output File>"
```

In addition, to these changes you need to import the system library into your script to access these arguments.

```
# Import the sys package from within the
# standard library
import sys
```

Please note that the list of user provided inputs starts at index 1 and not 0. If you call sys.argv[0] then the name of the script being executed will be returned. When retrieving values from the user in this form it is highly advisable to check whether the inputs provided are valid and that all required inputs have been provided.

Create a copy of the script you created earlier and edit the run function to be as shown above, making note of the lines which require editing.

7.4 Exercises

1. Using ogr2ogr develop a script that will convert the attribute table of a shapefile to a CSV file which can be opened within Microsoft Excel. Note, that the outputted CSV will be put into a separate directory.
2. Create a script which calls the gdal_translate command and converts all the images within a directory to a byte data type (i.e., with a range of 0 to 255).

Chapter 8

Image Processing using GDAL and RIOS

8.1 Reading and Updating Header Information

Image files used within spatial data processing (i.e., remote sensing and GIS) require the addition of a spatial header to the files which provides the origin (usually from the top left corner of the image), the pixel resolution of the image and a definition of the coordinate system and projection of the dataset. Additionally, most formats also allow a rotation to be defined. Using these fields the geographic position on the Earth's surface can be defined for each pixel within the scene.

Images can also contain other information in the header of the file including no data values, image statistics and band names/descriptions.

8.1.1 Reading Image Headers

The GDAL software library provides a python interface to the C++ library, such that when the python functions are called is it the C++ implementation which is executed. These model has significant advantages for operations such as reading and writing to and from image files as in pure python these operations would be slow but they as very fast within C++. Although, python is an easier language

for people to learn and use, therefore allows software to be more quickly developed so combing C++ and python in this way is a very productive way for software to be developed.

Argparser

Up until this point we have read parameters from the system by just using the sys.argv list where the user is required to enter the values in a given pre-defined order. The problem with this is that it is not very helpful to the user as no help is provided or error messages given if the wrong parameters are entered. For command line tools it is generally accepted that when providing command line options they will use switches such as -i or –input where the user specifies with a switch what the input they are providing is.

Fortunately, python provides a library to simplify the implementation of this type of interface. An example of this is shown below, where first the argparse library is imported. The parser is then created and the arguments added to the parser so the parser knows what to expect from the user. Finally, the parser is called to parse the arguments. Examples will be shown in all the following scripts.

```
1  # Import the python Argument parser
2  import argparse
3
4  # Create the parser
5  parser = argparse.ArgumentParser()
6  # Define the argument for specifying the input file.
7  parser.add_argument("-i", "--input", type=str, help="Specify the input image file.")
8  # Define the argument for specifying the output file.
9  parser.add_argument("-o", "--output", type=str, help="Specify the output text file.")
10 # Call the parser to parse the arguments.
11 args = parser.parse_args()
```

8.1.2 Read image header example.

The follow example demonstrates how to import the GDAL library into python and to read the image header information and print it to the console - similar to the functionality within the gdalinfo command. Read the comments within the code and ensure you understand the steps involved.

```
#!/usr/bin/env python

# Import the GDAL python library
import osgeo.gdal as gdal
# Import the python Argument parser
import argparse
# Import the System library
import sys

# Define a function to read and print the images
# header information.
def printImageHeader(inputFile):
    # Open the dataset in Read Only mode
    dataset = gdal.Open(inputFile, gdal.GA_ReadOnly)
    # Check that the dataset has correctly opened
    if not dataset is None:
        # Print out the image file path.
        print inputFile
        # Print out the number of image bands.
        print "The image has ", dataset.RasterCount, " bands."
        # Loop through all the image bands and print out the band name
        for n in range(dataset.RasterCount):
            print "\t", n+1, ":\t", dataset.GetRasterBand(n+1).GetDescription(), "\t"

        # Print out the image size in pixels
        print "Image Size [", dataset.RasterXSize, ",", dataset.RasterYSize, "]"

        # Get the geographic header
        # geotransform[0] = TL X Coordinate
        # geotransform[1] = X Pixel Resolution
        # geotransform[2] = X Rotation
        # geotransform[3] = TL Y Coordinate
        # geotransform[4] = Y Rotation
```

```
34          # geotransform[5] = Y Pixel Resolution
35          geotransform = dataset.GetGeoTransform()
36          # Check that the tranformation has been correctly read.
37          if not geotransform is None:
38              # Print out the Origin, Pixel Size and Rotation.
39              print 'Origin = (',geotransform[0], ',',geotransform[3],')'
40              print 'Pixel Size = (',geotransform[1], ',',geotransform[5],')'
41              print 'Rotation = (',geotransform[2], ',',geotransform[4],')'
42          else:
43              # Provide an error message is the transform has not been
44              # correctly read.
45              print "Could not find a geotransform for image file ", inputFile
46      else:
47          # Provide an error message if the input image file
48          # could not be opened.
49          print "Could not open the input image file: ", inputFile
50
51
52  # This is the first part of the script to
53  # be executed.
54  if __name__ == '__main__':
55      # Create the command line options
56      # parser.
57      parser = argparse.ArgumentParser()
58      # Define the argument for specifying the input file.
59      parser.add_argument("-i", "--input", type=str,
60                          help="Specify the input image file.")
61      # Call the parser to parse the arguments.
62      args = parser.parse_args()
63
64      # Check that the input parameter has been specified.
65      if args.input == None:
66          # Print an error message if not and exit.
67          print "Error: No input image file provided."
68          sys.exit()
69      # Otherwise, run the function to print out the image header information.
70      printImageHeader(args.input)
```

Running the script

Run the script as you have done others within these worksheets and as shown below, you need to provide the full path to the image file or copy the image file into the same directory as your script. This should result in an output like the one shown below:

```
> python ReadImageHeader.py -i LSTOA_Tanz_2000Wet.img
LSTOA_Tanz_2000Wet.img
The image has  6  bands.
        1 :        Band 1
        2 :        Band 2
        3 :        Band 3
        4 :        Band 4
        5 :        Band 5
        6 :        Band 6
Image Size [ 1776 , 1871 ]
Origin = ( 35.2128071515 , -3.05897460167 )
Pixel Size = ( 0.000271352299023 , -0.000271352299023 )
Rotation = ( 0.0 , 0.0 )
```

8.1.3 No Data Values

GDAL also allows us to edit the image header values, therefore the following example provides an example of how to edit the no data value for image band. Note that when opening the image file the gdal.GA_Update option is used rather than gdal.GA_ReadOnly.

A no data value is useful for defining regions of the image which are not valid (i.e., outside of the image boundaries) and can be ignored during processing.

Running the script

For the file provided (LSTOA_Tanz_2000Wet.img) the no data value for all the bands should be 0. Therefore, run the following command:

```
> python setnodata.py -i LSTOA_Tanz_2000Wet.img -n 0.0
Setting No data (0.0) for band 1
Setting No data (0.0) for band 2
Setting No data (0.0) for band 3
Setting No data (0.0) for band 4
Setting No data (0.0) for band 5
Setting No data (0.0) for band 6
```

To check that command successfully edited the input file use the gdalinfo command, as shown below:

```
gdalinfo -norat LSTOA_Tanz_2000Wet.img
```

```
#!/usr/bin/env python

# Import the GDAL python library
import osgeo.gdal as gdal
# Import the python Argument parser
import argparse
# Import the System library
import sys

# A function to set the no data value
# for each image band.
def setNoData(inputFile, noDataVal):
    # Open the image file, in update mode
    # so that the image can be edited.
    dataset = gdal.Open(inputFile, gdal.GA_Update)
    # Check that the image  has been opened.
    if not dataset is None:
        # Iterate throught he image bands
        # Note. i starts at 0 while the
        # band count in GDAL starts at 1.
        for i in range(dataset.RasterCount):
            # Print information to the user on what is
            # being set.
            print "Setting No data (" + str(noDataVal) + ") for band " + str(i+1)
            # Get the image band
            # the i+1 is because GDAL bands
```

```
27              # start with 1.
28              band = dataset.GetRasterBand(i+1)
29              # Set the no data value.
30              band.SetNoDataValue(noDataVal)
31      else:
32          # Print an error message if the file
33          # could not be opened.
34          print "Could not open the input image file: ", inputFile
35
36  # This is the first part of the script to
37  # be executed.
38  if __name__ == '__main__':
39      # Create the command line options
40      # parser.
41      parser = argparse.ArgumentParser()
42      # Define the argument for specifying the input file.
43      parser.add_argument("-i", "--input", type=str,
44                          help="Specify the input image file.")
45      # Define the argument for specifying the no data value.
46      parser.add_argument("-n", "--nodata", type=float, default=0,
47                          help="Specify the no data value to be set.")
48      # Call the parser to parse the arguments.
49      args = parser.parse_args()
50
51      # Check that the input parameter has been specified.
52      if args.input == None:
53          # Print an error message if not and exit.
54          print "Error: not input image file provided."
55          sys.exit()
56      # Otherwise, run the function to set the no
57      # data value.
58      setNoData(args.input, args.nodata)
```

8.1.4 Band Name

Band names are useful for a user to understand a data set more easily. Therefore, naming the image bands, such as Blue, Green, Red, NIR and SWIR, is very useful. The following example illustrates how to edit the band name description

using GDAL.

```
#!/usr/bin/env python

# Import the GDAL python library
import osgeo.gdal as gdal
# Import the python Argument parser
import argparse
# Import the System library
import sys

# A function to set the no data value
# for each image band.
def setBandName(inputFile, band, name):
    # Open the image file, in update mode
    # so that the image can be edited.
    dataset = gdal.Open(inputFile, gdal.GA_Update)
    # Check that the image  has been opened.
    if not dataset is None:
        # Get the image band
        imgBand = dataset.GetRasterBand(band)
        # Check the image band was available.
        if not imgBand is None:
            # Set the image band name.
            imgBand.SetDescription(name)
        else:
            # Print out an error message.
            print "Could not open the image band: ", band
    else:
        # Print an error message if the file
        # could not be opened.
        print "Could not open the input image file: ", inputFile

# This is the first part of the script to
# be executed.
if __name__ == '__main__':
    # Create the command line options
    # parser.
    parser = argparse.ArgumentParser()
    # Define the argument for specifying the input file.
    parser.add_argument("-i", "--input", type=str,
```

```
40                      help="Specify the input image file.")
41      # Define the argument for specifying image band.
42      parser.add_argument("-b", "--band", type=int,
43                      help="Specify image band.")
44      # Define the argument for specifying band name.
45      parser.add_argument("-n", "--name", type=str,
46                      help="Specify the band name.")
47      # Call the parser to parse the arguments.
48      args = parser.parse_args()
49
50      # Check that the input parameter has been specified.
51      if args.input == None:
52          # Print an error message if not and exit.
53          print "Error: No input image file provided."
54          sys.exit()
55
56      # Check that the band parameter has been specified.
57      if args.band == None:
58          # Print an error message if not and exit.
59          print "Error: the band was not specified."
60          sys.exit()
61
62      # Check that the name parameter has been specified.
63      if args.name == None:
64          # Print an error message if not and exit.
65          print "Error: the band name was not specified."
66          sys.exit()
67
68      # Otherwise, run the function to set the band
69      # name.
70      setBandName(args.input, args.band, args.name)
```

Running the script

The file provided (LSTOA_Tanz_2000Wet.img) just has some default band names defined (i.e., Band 1) but use you script to change them to something more useful. Therefore, run the following commands:

```
python setbandname.py -i LSTOA_Tanz_2000Wet.img -b 1 -n Blue
python setbandname.py -i LSTOA_Tanz_2000Wet.img -b 2 -n Green
python setbandname.py -i LSTOA_Tanz_2000Wet.img -b 3 -n Red
python setbandname.py -i LSTOA_Tanz_2000Wet.img -b 4 -n NIR
python setbandname.py -i LSTOA_Tanz_2000Wet.img -b 5 -n SWIR1
python setbandname.py -i LSTOA_Tanz_2000Wet.img -b 6 -n SWIR2
```

Use you script for reading the image header values and printing them to the screen to find out whether it worked.

8.1.5 GDAL Meta-Data

GDAL supports the concept of meta-data on both the image bands and the whole image. The meta-data allows any other data to be stored within the image file as a string.

The following example shows how to read the meta-data values and to list all the meta-data variables available on both the image bands and the image.

```
1  #!/usr/bin/env python
2
3  # Import the GDAL python library
4  import osgeo.gdal as gdal
5  # Import the python Argument parser
6  import argparse
7  # Import the System library
8  import sys
9
10 # A function to read a meta-data item
11 # from a image band
12 def readBandMetaData(inputFile, band, name):
13     # Open the dataset in Read Only mode
14     dataset = gdal.Open(inputFile, gdal.GA_ReadOnly)
15     # Check that the image  has been opened.
16     if not dataset is None:
17         # Get the image band
18         imgBand = dataset.GetRasterBand(band)
19         # Check the image band was available.
```

```
20          if not imgBand is None:
21              # Get the meta-data value specified.
22              metaData = imgBand.GetMetadataItem(name)
23              # Check that it is present
24              if metaData == None:
25                  # If not present, print error.
26                  print "Could not find \'", name, "\' item."
27              else:
28                  # Else print out the metaData value.
29                  print name, " = \'", metaData, "\'"
30          else:
31              # Print out an error message.
32              print "Could not open the image band: ", band
33      else:
34          # Print an error message if the file
35          # could not be opened.
36          print "Could not open the input image file: ", inputFile
37
38  # A function to read a meta-data item
39  # from a image
40  def readImageMetaData(inputFile, name):
41      # Open the dataset in Read Only mode
42      dataset = gdal.Open(inputFile, gdal.GA_ReadOnly)
43      # Check that the image  has been opened.
44      if not dataset is None:
45          # Get the meta-data value specified.
46          metaData = dataset.GetMetadataItem(name)
47          # Check that it is present
48          if metaData == None:
49              # If not present, print error.
50              print "Could not find \'", name, "\' item."
51          else:
52              # Else print out the metaData value.
53              print name, " = \'", metaData, "\'"
54      else:
55          # Print an error message if the file
56          # could not be opened.
57          print "Could not open the input image file: ", inputFile
58
59  # A function to read a meta-data item
60  # from a image band
```

```
61 def listBandMetaData(inputFile, band):
62     # Open the dataset in Read Only mode
63     dataset = gdal.Open(inputFile, gdal.GA_ReadOnly)
64     # Check that the image  has been opened.
65     if not dataset is None:
66         # Get the image band
67         imgBand = dataset.GetRasterBand(band)
68         # Check the image band was available.
69         if not imgBand is None:
70             # Get the meta-data dictionary
71             metaData = imgBand.GetMetadata_Dict()
72             # Check it has entries.
73             if len(metaData) == 0:
74                 # If it has no entries return
75                 # error message.
76                 print "There is no image meta-data."
77             else:
78                 # Otherwise, print out the
79                 # meta-data.
80                 # Loop through each entry.
81                 for metaItem in metaData:
82                     print metaItem
83         else:
84             # Print out an error message.
85             print "Could not open the image band: ", band
86     else:
87         # Print an error message if the file
88         # could not be opened.
89         print "Could not open the input image file: ", inputFile
90 
91 # A function to read a meta-data item
92 # from a image
93 def listImageMetaData(inputFile):
94     # Open the dataset in Read Only mode
95     dataset = gdal.Open(inputFile, gdal.GA_ReadOnly)
96     # Check that the image  has been opened.
97     if not dataset is None:
98         # Get the meta-data dictionary
99         metaData = dataset.GetMetadata_Dict()
100         # Check it has entries.
101         if len(metaData) == 0:
```

```
102             # If it has no entries return
103             # error message.
104             print "There is no image meta-data."
105         else:
106             # Otherwise, print out the
107             # meta-data.
108             # Loop through each entry.
109             for metaItem in metaData:
110                 print metaItem
111     else:
112         # Print an error message if the file
113         # could not be opened.
114         print "Could not open the input image file: ", inputFile
115 
116 # This is the first part of the script to
117 # be executed.
118 if __name__ == '__main__':
119     # Create the command line options
120     # parser.
121     parser = argparse.ArgumentParser()
122     # Define the argument for specifying the input file.
123     parser.add_argument("-i", "--input", type=str,
124                         help="Specify the input image file.")
125     # Define the argument for specifying image band.
126     parser.add_argument("-b", "--band", type=int, default=0,
127                         help="Specify image band.")
128     # Define the argument for specifying meta-data name.
129     parser.add_argument("-n", "--name", type=str,
130                         help="Specify the meta-data name.")
131     # Define the argument for specifying whether the
132     # meta-data field should be just listed.
133     parser.add_argument("-l", "--list", action="store_true", default=False,
134                         help="Specify that meta data items should be listed.")
135     # Call the parser to parse the arguments.
136     args = parser.parse_args()
137 
138     # Check that the input parameter has been specified.
139     if args.input == None:
140         # Print an error message if not and exit.
141         print "Error: No input image file provided."
142         sys.exit()
```

```
143
144     # Check that the name parameter has been specified.
145     # If it has been specified then run functions to
146     # read band meta-data.
147     if not args.name == None:
148         # Check whether the image band has been specified.
149         # the default was set at 0 (to indicate that it)
150         # hasn't been specified as GDAL band count starts
151         # at 1. This also means the user cannot type in
152         # a value of 0 and get an error.
153         if args.band == 0:
154             # Run the function to print out the image meta-data value.
155             readImageMetaData(args.input, args.name)
156         else:
157             # Otherwise, run the function to print out the band meta-data value.
158             readBandMetaData(args.input, args.band, args.name)
159     elif args.list:
160         if args.band == 0:
161             # Run the function to list image meta-data.
162             listImageMetaData(args.input)
163         else:
164             # Otherwise, run the function to list band meta-data.
165             listBandMetaData(args.input, args.band)
166     else:
167         # Print an error message if not and exit.
168         print "Error: the meta-data name or list option" + \
169               " need to be specified was not specified."
170         sys.exit()
```

Running the script

This script has a number of options. Have a play with these options on the image provided, an example shown below.

```
python ReadGDALMetaData.py -h
python ReadGDALMetaData.py -i LSTOA_Tanz_2000Wet.img  -l
python ReadGDALMetaData.py -i LSTOA_Tanz_2000Wet.img  -b 1 -l
python ReadGDALMetaData.py -i LSTOA_Tanz_2000Wet.img  -b 1 -n LAYER_TYPE
python ReadGDALMetaData.py -i LSTOA_Tanz_2000Wet.img  -b 3 -n STATISTICS_MEAN
```

8.2 Raster Input / Output Simplification (RIOS) Library

The raster input and output (I/O) simplification (RIOS) library is a set of python modules which makes it easier to write raster processing code in Python. Built on top of GDAL, it handles the details of opening and closing files, checking alignment of projections and raster grid, stepping through the raster in small blocks, etc., allowing the programmer to concentrate on implementing the solution to the problem rather than on how to access the raster data and detail with the spatial header.

Also, GDAL provides access to the image data through python RIOS makes it much more user friendly and easier to use. RIOS is available for as a free download from `https://bitbucket.org/chchrsc/rios/overview`

8.2.1 Getting Help – Reminder

Python provides a very useful help system through the command line. To get access to the help run python from the terminal

```
> python
```

Then import the library want to get help on

```
>>> import osgeo.gdal
```

and then run the help tool on the whole module

```
>>> import osgeo.gdal
>>> help(osgeo.gdal)
```

or on individual classes within the module

```
>>> import osgeo.gdal
>>> help(osgeo.gdal.Dataset)
```

To exit the help system just press the 'q' key on the keyboard.

8.2.2 Band Maths

Being able to apply equations to combine image bands, images or scale single bands is a key tool for remote sensing, for example to calibrate Landsat to radiance. The following examples demonstrate how to do this within the RIOS framework.

8.2.3 Multiply by a constant

The first example just multiples all the image bands by a constant (provided by the user). The first part of the code reads the users parameters (input file, output file and scale factor). To use the applier interface within RIOS you need to first setup the input and output file associations and then any other options required, in this case the constant for multiplication. Also, the controls object should be defined to set any other parameters

All processing within RIOS is undertaken on blocks, by default 200×200 pixels in size. To process the block a applier function needs to be defined (e.g., mutliplyByValue) where the inputs and outputs are passed to the function (these are the pixel values) and the other arguments object previously defined. The pixel values are represented as a numpy array, the dimensions are (n, y, x) where n is the number of image bands, y is the number of rows and x the number of columns in the block.

Because numpy will iterate through the array for us to multiply the whole array by a constant (e.g., 2) then we can just need the syntax shown below, which makes it very simple.

```
1 #!/usr/bin/env python
2
3 # Import the python Argument parser
4 import argparse
5 # Import the RIOS applier interface
6 from rios import applier
```

```
7  from rios import cuiprogress
8
9  # Define the applier function
10 def mutliplyByValue(info, inputs, outputs, otherargs):
11     # Multiple the image1 by the scale factor
12     outputs.outimage = inputs.image1 * otherargs.scale
13
14 # This is the first part of the script to
15 # be executed.
16 if __name__ == '__main__':
17     # Create the command line options
18     # parser.
19     parser = argparse.ArgumentParser()
20     # Define the argument for specifying the input file.
21     parser.add_argument("-i", "--input", type=str,
22                         help="Specify the input image file.")
23     # Define the argument for specifying the output file.
24     parser.add_argument("-o", "--output", type=str,
25                         help="Specify the output image file.")
26     # Define the argument for multiply the image by.
27     parser.add_argument("-m", "--multiply", default=1.0, type=float,
28                         help="Multiple the image by.")
29     # Call the parser to parse the arguments.
30     args = parser.parse_args()
31
32     # Check that the input parameter has been specified.
33     if args.input == None:
34         # Print an error message if not and exit.
35         print "Error: No input image file provided."
36         sys.exit()
37
38     # Check that the output parameter has been specified.
39     if args.output == None:
40         # Print an error message if not and exit.
41         print "Error: No output image file provided."
42         sys.exit()
43
44     # Create input files file names associations
45     infiles = applier.FilenameAssociations()
46     # Set image1 to the input image specified
47     infiles.image1 = args.input
```

```
48      # Create output files file names associations
49      outfiles = applier.FilenameAssociations()
50      # Set outImage to the output image specified
51      outfiles.outimage = args.output
52      # Create other arguments object
53      otherargs = applier.OtherInputs()
54      # Define the scale arguments
55      otherargs.scale = args.multiply
56      # Create a controls objects
57      aControls = applier.ApplierControls()
58      # Set the progress object.
59      aControls.progress = cuiprogress.CUIProgressBar()
60
61      # Apply the multiply function.
62      applier.apply(mutliplyByValue,
63                    infiles,
64                    outfiles,
65                    otherargs,
66                    controls=aControls)
67
```

Run the Script

Run the script using the following command, the input image is a Landsat scene and all the pixel values will be multiplied by 2.

```
python MultiplyRIOSExample.py -i LSTOA_Tanz_2000Wet.img \
       -o LSTOA_Tanz_2000Wet_Multiby2.img -m 2
```

8.2.4 Calculate NDVI

To use the image bands independently to calculate a new value, usually indices such as the NDVI

$$\text{NDVI} = \frac{\text{NIR} + \text{RED}}{\text{NIR} - \text{RED}} \tag{8.1}$$

requires that the bands are referenced independently within the input data. Using numpy to calculate the index, as shown below, results in a single output block with the dimensions of the block but does not have the third dimension (i.e., the band) which is required for RIOS to identify how to create the output image. Therefore, as you will see in the example below an extra dimension needs to be added before outputting the data to the file. Within the example given the input pixel values are converted to floating point values (rather than whatever they were inputted as from the input) because the output will be a floating point number (i.e., an NDVI have a range of -1 to 1).

```
#!/usr/bin/env python

# Import the python Argument parser
import argparse
# Import the RIOS applier interface
from rios import applier
from rios import cuiprogress
#
import numpy

# Define the applier function
def mutliplyByValue(info, inputs, outputs, otherargs):
    # Convert the input data to Float32
    # This is because the output is a float due to the
    # divide within the NDVI calculation.
    inputs.image1 = inputs.image1.astype (numpy.float32)
    # Calculate the NDVI for the block.
    # Note. Numpy will deal with the image iterating
    #       to all the individual pixels values.
    #       within python this is very important
    #       as python loops are slow.
    out = ((inputs.image1[otherargs.nirband]-
           inputs.image1[otherargs.redband])
           /
          (inputs.image1[otherargs.nirband]+
          inputs.image1[otherargs.redband]))
    # At an extra dimension to the output array.
    # The output array needs to have 3 dimensions
    # (No Bands, Y Pixels(Rows), X Pixels(Cols)
```

```
30      # In this case an extra dimension representing
31      # the single image band is required.
32      outputs.outimage = numpy.expand_dims(out, axis=0)
33
34  # This is the first part of the script to
35  # be executed.
36  if __name__ == '__main__':
37      # Create the command line options
38      # parser.
39      parser = argparse.ArgumentParser()
40      # Define the argument for specifying the input file.
41      parser.add_argument("-i", "--input", type=str,
42                          help="Specify the input image file.")
43      # Define the argument for specifying the output file.
44      parser.add_argument("-o", "--output", type=str,
45                          help="Specify the output image file.")
46      # Define the argument for specifying the red image band
47      parser.add_argument("-r", "--red", type=int,
48                          help="Specifiy red band.")
49      # Define the argument for specifying the NIR image band
50      parser.add_argument("-n", "--nir", type=int,
51                          help="Specifiy NIR band.")
52      # Call the parser to parse the arguments.
53      args = parser.parse_args()
54
55      # Check that the input parameter has been specified.
56      if args.input == None:
57          # Print an error message if not and exit.
58          print "Error: No input image file provided."
59          sys.exit()
60
61      # Check that the output parameter has been specified.
62      if args.output == None:
63          # Print an error message if not and exit.
64          print "Error: No output image file provided."
65          sys.exit()
66
67      # Create input files file names associations
68      infiles = applier.FilenameAssociations()
69      # Set image1 to the input image specified
70      infiles.image1 = args.input
```

```
71      # Create output files file names associations
72      outfiles = applier.FilenameAssociations()
73      # Set outImage to the output image specified
74      outfiles.outimage = args.output
75      # Create other arguments object
76      otherargs = applier.OtherInputs()
77      # Define the red band argument
78      otherargs.redband = args.red-1
79      # Define the NIR band argument
80      otherargs.nirband = args.nir-1
81      # Create a controls objects
82      aControls = applier.ApplierControls()
83      # Set the progress object.
84      aControls.progress = cuiprogress.CUIProgressBar()
85
86      # Apply the multiply function.
87      applier.apply(mutliplyByValue,
88                    infiles,
89                    outfiles,
90                    otherargs,
91                    controls=aControls)
92
```

Run the Script

Run the script using the following command, the input image is a Landsat scene so the red band is therefore band 3 and then NIR band is band 4.

```
python RIOSExampleNDVI.py -i LSTOA_Tanz_2000Wet.img \
       -o LSTOA_Tanz_2000Wet_NDVI.img -r 3 -n 4
```

8.2.5 Calculate NDVI Using Multiple Images

Where multiple input files are required, in this case the NIR and Red bands are represented by different image files, the input files need to be specified in the input files association as image1, image2 etc. and the pixel values within the applier

function are therefore referenced in the same way. Because, in this example the images only have a single image band the input images has the same dimensions as the output so no extra dimensions need to be added.

```
#!/usr/bin/env python

# Import the system library
import sys
# Import the python Argument parser
import argparse
# Import the RIOS applier interface
from rios import applier
# Import the RIOS progress feedback
from rios import cuiprogress
# Import the numpy library
import numpy

# Define the applier function
def mutliplyByValue(info, inputs, outputs):
    # Convert the input data to Float32
    # This is because the output is a float due to the
    # divide within the NDVI calculation.
    inputs.image1 = inputs.image1.astype (numpy.float32)
    inputs.image2 = inputs.image2.astype (numpy.float32)
    # Calculate the NDVI for the block.
    # Note. Numpy will deal with the image iterating
    #       to all the individual pixels values.
    #       within python this is very important
    #       as python loops are slow.
    outputs.outimage = ((inputs.image2-inputs.image1)
                        /
                        (inputs.image2+inputs.image1))

# This is the first part of the script to
# be executed.
if __name__ == '__main__':
    # Create the command line options
    # parser.
    parser = argparse.ArgumentParser()
    # Define the argument for specifying the output file.
```

```
37      parser.add_argument("-o", "--output", type=str,
38                          help="Specify the output image file.")
39      # Define the argument for specifying the red image band
40      parser.add_argument("-r", "--red", type=str,
41                          help="Specifiy red input image file.")
42      # Define the argument for specifying the NIR image band
43      parser.add_argument("-n", "--nir", type=str,
44                          help="Specifiy NIR input image file.")
45      # Call the parser to parse the arguments.
46      args = parser.parse_args()
47
48      # Check that the red input parameter has been specified.
49      if args.red == None:
50          # Print an error message if not and exit.
51          print "Error: No red input image file provided."
52          sys.exit()
53
54      # Check that the NIR input parameter has been specified.
55      if args.red == None:
56          # Print an error message if not and exit.
57          print "Error: No NIR input image file provided."
58          sys.exit()
59
60      # Check that the output parameter has been specified.
61      if args.output == None:
62          # Print an error message if not and exit.
63          print "Error: No output image file provided."
64          sys.exit()
65
66      # Create input files file names associations
67      infiles = applier.FilenameAssociations()
68      # Set images to the input image specified
69      infiles.image1 = args.red
70      infiles.image2 = args.nir
71      # Create output files file names associations
72      outfiles = applier.FilenameAssociations()
73      # Set outImage to the output image specified
74      outfiles.outimage = args.output
75      # Create a controls objects
76      aControls = applier.ApplierControls()
77      # Set the progress object.
```

```
78      aControls.progress = cuiprogress.CUIProgressBar()
79
80      # Apply the multiply function.
81      applier.apply(mutliplyByValue,
82                    infiles,
83                    outfiles,
84                    controls=aControls)
85
```

Run the Script

Run the script using the following command, the input image is a Landsat scene so the red band is therefore band 3 and then NIR band is band 4.

```
python RIOSExampleMultiFileNDVI.py -o LSTOA_Tanz_2000Wet_MultiIn_NDVI.img \
       -r LSTOA_Tanz_2000Wet_Red.img -n LSTOA_Tanz_2000Wet_NIR.img
```

8.3 Filtering Images

To filtering an image is done through a windowing operation where the windows of pixels, such as a 3×3 or 5×5 (it needs to be an odd number), are selected and a new value for the centre pixel is calculated using all the pixel values within the window. In this example a median filter will be used so the middle pixel value will be replaced with the median value of the window.

Scipy (`http://www.scipy.org`) is another library of python functions, which is paired with numpy, and provides many useful functions we can use when processing the images or other datasets within python. The ndimage module (`http://docs.scipy.org/doc/scipy/reference/tutorial/ndimage.html`) provides many useful functions, which can be applied to images in the same way as the median filter has been used in the example below – I strongly recommend you look through the documentation of scipy to get an idea of the types of functions which are available.

```
#!/usr/bin/env python

import sys
# Import the python Argument parser
import argparse
# Import the scipy filters.
from scipy import ndimage
#Import the numpy library
import numpy
# Import the RIOS image reader
from rios.imagereader import ImageReader
# Import the RIOS image writer
from rios.imagewriter import ImageWriter

# Define the function to iterate through
# the image.
def applyMedianFilter(inputFile, outputFile, fSize):
    # Get half the filter size, overlap between blocks
    hSize = (fSize-1)/2
    # Create the image reader for the input file
    # and set the overlap to be half the image
    # filter size.
    reader = ImageReader(inputFile, overlap=hSize)
    # Define the image writer but cannot create
    # until within the loop as this need the
    # information within the info object.
    writer = None
    # Loop through all the image blocks within
    # the reader.
    for (info, block) in reader:
        # Create an output block of
        # the same size as the input
        out = numpy.zeros_like(block)
        # Iterate through the image bands
        for i in range(len(out)):
            # Use scipy to run a median filter
            # on the image band data. The image
            # bands are filtered in turn
            ndimage.median_filter(block[i],size=fSize,output=out[i])
        # If it is the first time through the loop
        # (i.e., writer has a value of None) then
```

```
42          # create the loop.
43          if writer is None:
44              # Create the writer for output image.
45              writer = ImageWriter(outputFile,
46                                   info=info,
47                                   firstblock=out,
48                                   drivername='HFA')
49          else:
50              # If the writer is created write the
51              # output block to the file.
52              writer.write(out)
53      # Close the writer and calculate
54      # the image statistics.
55      writer.close(calcStats=True)
56
57  # This is the first part of the script to
58  # be executed.
59  if __name__ == '__main__':
60      # Create the command line options
61      # parser.
62      parser = argparse.ArgumentParser()
63      # Define the argument for specifying the input file.
64      parser.add_argument("-i", "--input", type=str,
65                          help="Specify the input image file.")
66      # Define the argument for specifying the output file.
67      parser.add_argument("-o", "--output", type=str,
68                          help="Specify the output image file.")
69      # Define the argument for the size of the image filter.
70      parser.add_argument("-s", "--size", default=3, type=int,
71                          help="Filter size.")
72      # Call the parser to parse the arguments.
73      args = parser.parse_args()
74
75      # Check that the input parameter has been specified.
76      if args.input == None:
77          # Print an error message if not and exit.
78          print "Error: No input image file provided."
79          sys.exit()
80
81      # Check that the output parameter has been specified.
82      if args.output == None:
```

```
83          # Print an error message if not and exit.
84          print "Error: No output image file provided."
85          sys.exit()
86
87      # Call the function to execute a median filter
88      # on the input image.
89      applyMedianFilter(args.input, args.output, args.size)
90
```

Run the Script

```
python MedianFilterRIOSExample.py -i LSTOA_Tanz_2000Wet.img \
                                  -o LSTOA_Tanz_2000Wet_median7.img -s 7
```

After you have run this command open the images in the image viewer and flick between them to observe the change in the image, what do you notice?

8.4 Apply a rule based classification

Another option we have is to use the 'where' function within numpy to select pixel corresponding to certain criteria (i.e., pixels with an NDVI < 0.2 is not vegetation) and classify them accordingly where a pixel values are used to indicate the corresponding class (e.g., 1 = Forest, 2 = Water, 3 = Grass, etc). These images where pixel values are not continuous but categories are referred to as thematic images and there is a header value that can be set to indicate this type of image. Therefore, in the script below there is a function for setting the image band metadata field 'LAYER_TYPE' to be 'thematic'. Setting an image as thematic means that the nearest neighbour algorithm will be used when calculating pyramids and histograms needs to be binned with single whole values. It also means that a colour table (See Chapter 9) can also be added.

To build the rule base the output pixel values need to be created, here using the numpy function zeros (`http://docs.scipy.org/doc/numpy/reference/generated/numpy.zeros.html`). The function zeros creates a numpy array of the requested

shape (in this case the shape is taken from the inputted image) where all the pixels have a value of zero.

Using the 'where' function (`http://docs.scipy.org/doc/numpy/reference/generated/numpy.where.html`) a logic statement can be applied to an array or set of arrays (which must be of the same size) to select the pixels for which the statement is true. The where function returns an array of indexes which can be used to address another array (i.e., the output array) and set a suitable output value (i.e., the classification code).

```
#!/usr/bin/env python

# Import the system library
import sys
# Import the python Argument parser
import argparse
# Import the RIOS applier interface
from rios import applier
# Import the RIOS progress feedback
from rios import cuiprogress
# Import the numpy library
import numpy
# Import the GDAL library
from osgeo import gdal

# Define the applier function
def rulebaseClassifier(info, inputs, outputs):
    # Create an output array with the same dims
    # as a single band of the input file.
    out = numpy.zeros(inputs.image1[0].shape)
    # Use where statements to select the
    # pixels to be classified. Give them a
    # integer value (i.e., 1, 2, 3, 4) to
    # specify the class.
    out[numpy.where((inputs.image1[0] > 0.4 )&(inputs.image1[0] < 0.7))] = 1
    out[numpy.where(inputs.image1[0] < 0.1 )] = 2
    out[numpy.where((inputs.image1[0] > 0.1 )&(inputs.image1[0] < 0.4))] = 3
    out[numpy.where(inputs.image1[0] > 0.7 )] = 4
    # Expand the output array to include a single
    # image band and set as the output dataset.
```

```
31      outputs.outimage = numpy.expand_dims(out, axis=0)
32
33  # A function to define the image as thematic
34  def setThematic(imageFile):
35      # Use GDAL to open the dataset
36      ds = gdal.Open(imageFile, gdal.GA_Update)
37      # Iterate through the image bands
38      for bandnum in range(ds.RasterCount):
39          # Get the image band
40          band = ds.GetRasterBand(bandnum + 1)
41          # Define the meta-data for the LAYER_TYPE
42          band.SetMetadataItem('LAYER_TYPE', 'thematic')
43
44  # This is the first part of the script to
45  # be executed.
46  if __name__ == '__main__':
47      # Create the command line options
48      # parser.
49      parser = argparse.ArgumentParser()
50      # Define the argument for specifying the input file.
51      parser.add_argument("-i", "--input", type=str,
52                          help="Specify the input image file.")
53      # Define the argument for specifying the output file.
54      parser.add_argument("-o", "--output", type=str,
55                          help="Specify the output image file.")
56      # Call the parser to parse the arguments.
57      args = parser.parse_args()
58
59      # Check that the input parameter has been specified.
60      if args.input == None:
61          # Print an error message if not and exit.
62          print "Error: No input image file provided."
63          sys.exit()
64
65      # Check that the output parameter has been specified.
66      if args.output == None:
67          # Print an error message if not and exit.
68          print "Error: No output image file provided."
69          sys.exit()
70
71      # Create input files file names associations
```

```
    infiles = applier.FilenameAssociations()
    # Set image1 to the input image specified
    infiles.image1 = args.input
    # Create output files file names associations
    outfiles = applier.FilenameAssociations()
    # Set outImage to the output image specified
    outfiles.outimage = args.output
    # Create a controls objects
    aControls = applier.ApplierControls()
    # Specify that stats shouldn't be calc'd
    aControls.calcStats = False
    # Set the progress object.
    aControls.progress = cuiprogress.CUIProgressBar()

    # Apply the classifier function.
    applier.apply(rulebaseClassifier,
                  infiles,
                  outfiles,
                  controls=aControls)

    # Set the output file to be thematic
    setThematic(args.output)
```

Run the Script

Run the script with one of the NDVI layers you previously calculated. To see the result then it is recommended that a colour table is added (see next worksheet), the easiest way to do that is to use the gdalcalcstats command, as shown below.

```
python RuleBaseClassification.py -i LSTOA_Tanz_2000Wet_NDVI.img \
                                 -o LSTOA_Tanz_2000Wet_classification.img
# Run gdalcalcstats to add a random colour table
gdalcalcstats LSTOA_Tanz_2000Wet_classification.img
```

8.5 Exercises

1. Create rule based classification using multiple image bands.
2. Create a rule based classification using image bands from different input images.
3. Using the previous work sheet as a basis create a script which calls the gdalwarp command to resample an input image to the same pixel resolution as another image, where the header is read as shown in this work sheet.

Chapter 9

Raster Attribute Tables (RAT)

The RIOS software also allows raster attribute tables to be read and written through GDAL. Raster attribute tables (RAT) are similar the the attribute tables which are present on a vector (e.g., shapefile). Each row of the attribute table refers to a pixel value within the image (e.g., row 0 refers to all pixels with a value of 0). Therefore, RATs are used within thematic datasets were pixels values are integers and refer to a category, such as a class from a classification, or a spatial region, such as a segment from a segmentation. The columns of the RAT therefore refer to variables, which correspond to information associated with the spatial region cover by the image pixels of the clump(s) relating to the row within the attribute table.

9.1 Reading Columns

To access the RAT using RIOS, you need to import the rat module. The RAT module provides a simple interface for reading and writing columns. When a column is read it is returned as a numpy array where the size is $n \times 1$ (i.e., the number of rows in the attribute table).

As shown in the example below, a reading a column is just a single function call specifying the input image file and the column name.

```
#!/usr/bin/env python

# Import the system library
import sys
# Import the RIOS rat library.
from rios import rat
# Import the python Argument parser
import argparse

# A function for reading the RAT
def readRatCol(imageFile, colName):
    # Use RIOS to read the column name
    # The contents of the column are
    # printed to the console for the
    # user to see.
    print rat.readColumn(imageFile, colName)

# This is the first part of the script to
# be executed.
if __name__ == '__main__':
    # Create the command line options
    # parser.
    parser = argparse.ArgumentParser()
    # Define the argument for specifying the input file.
    parser.add_argument("-i", "--input", type=str,
                        help="Specify the input image file.")
    # Define the argument for specifying the column name.
    parser.add_argument("-n", "--name", type=str,
                        help="Specify the column name.")
    # Call the parser to parse the arguments.
    args = parser.parse_args()

    # Check that the input parameter has been specified.
    if args.input == None:
        # Print an error message if not and exit.
        print "Error: No input image file provided."
        sys.exit()
    # Check that the input parameter has been specified.
    if args.name == None:
        # Print an error message if not and exit.
        print "Error: No RAT column name provided."
```

```
42          sys.exit()
43
44      # Run the function read and print the
45      # RAT column.
46      readRatCol(args.input, args.name)
```

Run the Script

Run the script as follow, the example below prints the Histogram but use the viewer to see what other columns are within the attribute table.

```
python ReadRATColumn.py -i WV2_525N040W_2m_segments.kea -n Histogram
```

9.2 Writing Columns

Writing a column is also quite straight forward just requiring a $n \times 1$ numpy array with the the data to be written to the output file, the image file path and the name of the column to be written to.

9.2.1 Calculating New Columns

The first example reads a column from the input image and just multiples it by 2 and writes it to the image file as a new column.

```
1  #!/usr/bin/env python
2
3  # Import the system library
4  import sys
5  # Import the RIOS rat library.
6  from rios import rat
7  # Import the python Argument parser
8  import argparse
9
10 # The applier function to multiply the input
```

```
11  # column by 2.
12  def multiplyRATCol(imageFile, inColName, outColName):
13      # Read the input column
14      col = rat.readColumn(imageFile, inColName)
15      # Muliply the column by 2.
16      col = col * 2
17      # Write the output column to the file.
18      rat.writeColumn(imageFile, outColName, col)
19
20  # This is the first part of the script to
21  # be executed.
22  if __name__ == '__main__':
23      # Create the command line options
24      # parser.
25      parser = argparse.ArgumentParser()
26      # Define the argument for specifying the input file.
27      parser.add_argument("-i", "--input", type=str,
28                          help="Specify the input image file.")
29      # Define the argument for specifying the input column name.
30      parser.add_argument("-c", "--inname", type=str,
31                          help="Specify the input column name.")
32      # Define the argument for specifying the output column name.
33      parser.add_argument("-o", "--outname", type=str,
34                          help="Specify the output column name.")
35      # Call the parser to parse the arguments.
36      args = parser.parse_args()
37
38      # Check that the input parameter has been specified.
39      if args.input == None:
40          # Print an error message if not and exit.
41          print "Error: No input image file provided."
42          sys.exit()
43      # Check that the input parameter has been specified.
44      if args.inname == None:
45          # Print an error message if not and exit.
46          print "Error: No input RAT column name provided."
47          sys.exit()
48      # Check that the input parameter has been specified.
49      if args.outname == None:
50          # Print an error message if not and exit.
51          print "Error: No output RAT column name provided."
```

```
52          sys.exit()
53
54      # Otherwise, run the function to multiply the input column by 2.
55      multiplyRATCol(args.input, args.inname, args.outname)
```

Run the Script

Run the script as follows, in this simple case the histogram will be multiplied by 2 and saved as a new column.

```
python MultiplyColumn.py -i WV2_525N040W_2m_segments.kea -c Histogram -o HistoMulti2
```

9.2.2 Add Class Name

A useful column to have within the attribute table, where a classification has been undertaken, is class names. This allows a user to click on the image and rather than having to remember which codes correspond to which class they will be shown a class name.

To add class names to the attribute table a new column needs to be created, where the data type is set to be ASCII (string). To do this a copy of the histogram column is made where the new numpy array is empty, of type string and the same length at the histogram.

The following line using the ... syntax within the array index to specify all elements of the array, such that they are all set to a value of "NA".

Once the new column has been created then the class names can be simply defined through referencing the appropriate array index.

```
1  #!/usr/bin/env python
2
3  # Import the system library
4  import sys
5  # Import the RIOS rat library.
6  from rios import rat
```

```
7  # Import the python Argument parser
8  import argparse
9  # Import the numpy library
10 import numpy
11
12 # A function to add a colour table.
13 def addClassNames(imageFile):
14     histo = rat.readColumn(imageFile, "Histogram")
15     className = numpy.empty_like(histo, dtype=numpy.dtype('a255'))
16     className[...] = "NA"
17     className[0] = "Other Vegetation"
18     className[1] = "Low Woody Vegetation"
19     className[2] = "Water"
20     className[3] = "Sparse Vegetation"
21     className[4] = "Tall Woody Vegetation"
22     # Write the output column to the file.
23     rat.writeColumn(imageFile, "ClassNames", className)
24
25 # This is the first part of the script to
26 # be executed.
27 if __name__ == '__main__':
28     # Create the command line options
29     # parser.
30     parser = argparse.ArgumentParser()
31     # Define the argument for specifying the input file.
32     parser.add_argument("-i", "--input", type=str,
33                         help="Specify the input image file.")
34     # Call the parser to parse the arguments.
35     args = parser.parse_args()
36
37     # Check that the input parameter has been specified.
38     if args.input == None:
39         # Print an error message if not and exit.
40         print "Error: No input image file provided."
41         sys.exit()
42
43     # Run the add class names function
44     addClassNames(args.input)
```

Run the Script

Run the script as follows, use the classification you did at the end of worksheet 8.

```
python AddClassNames.py -i LSTOA_Tanz_2000Wet_classification.img
```

9.3 Adding a colour table

Another useful tool is being able to add a colour table to an image, such that classes are displayed in colours appropriate to make interpretation easier. To colour up the per pixel classification undertake at the end of the previous exercise and given class names using the previous scripts the following script is used to add a colour table.

The colour table is represented as an $n \times 5$ dimensional array, where n is the number of colours which are to be present within the colour table.

The 5 values associated with each colour are

1. Image Pixel Value
2. Red (0 – 255)
3. Green (0 – 255)
4. Blue (0 – 255)
5. Opacity (0 – 255)

Where an opacity of 0 means completely transparent and 255 means solid with no transparency (opacity is something also referred to as alpha or alpha channel).

```
1 #!/usr/bin/env python
2
3 # Import the system library
4 import sys
```

```
5  # Import the RIOS rat library.
6  from rios import rat
7  # Import the python Argument parser
8  import argparse
9  # Import the numpy library
10 import numpy
11
12 # A function to add a colour table.
13 def addColourTable(imageFile):
14     # Create a colour table (n,5) where
15     # n is the number of classes to be
16     # coloured. The data type must be
17     # of type integer.
18     ct = numpy.zeros([5,5], dtype=numpy.int)
19
20     # Set 0 to be Dark Mustard Yellow.
21     ct[0][0] = 0   # Pixel Val
22     ct[0][1] = 139 # Red
23     ct[0][2] = 139 # Green
24     ct[0][3] = 0   # Blue
25     ct[0][4] = 255 # Opacity
26
27     # Set 1 to be Dark Olive Green.
28     ct[1][0] = 1   # Pixel Val
29     ct[1][1] = 162 # Red
30     ct[1][2] = 205 # Green
31     ct[1][3] = 90  # Blue
32     ct[1][4] = 255 # Opacity
33
34     # Set 2 to be Royal Blue.
35     ct[2][0] = 2   # Pixel Val
36     ct[2][1] = 72  # Red
37     ct[2][2] = 118 # Green
38     ct[2][3] = 255 # Blue
39     ct[2][4] = 255 # Opacity
40
41     # Set 3 to be Dark Sea Green.
42     ct[3][0] = 3   # Pixel Val
43     ct[3][1] = 180 # Red
44     ct[3][2] = 238 # Green
45     ct[3][3] = 180 # Blue
```

```
46      ct[3][4] = 255 # Opacity
47
48      # Set 4 to be Forest Green.
49      ct[4][0] = 4    # Pixel Val
50      ct[4][1] = 34 # Red
51      ct[4][2] = 139 # Green
52      ct[4][3] = 34   # Blue
53      ct[4][4] = 255 # Opacity
54
55      rat.setColorTable(imageFile, ct)
56
57
58
59  # This is the first part of the script to
60  # be executed.
61  if __name__ == '__main__':
62      # Create the command line options
63      # parser.
64      parser = argparse.ArgumentParser()
65      # Define the argument for specifying the input file.
66      parser.add_argument("-i", "--input", type=str,
67                          help="Specify the input image file.")
68      # Call the parser to parse the arguments.
69      args = parser.parse_args()
70
71      # Check that the input parameter has been specified.
72      if args.input == None:
73          # Print an error message if not and exit.
74          print "Error: No input image file provided."
75          sys.exit()
76
77      # Run the add colour table function
78      addColourTable(args.input)
```

Run the Script

Run the script as follows, use the classification you did at the end of worksheet 8.

```
python AddClassNames.py -i LSTOA_Tanz_2000Wet_classification.img
```

To find the Red, Green and Blue (RGB) values to use with the colour table there are many websites available only that provide lists of these colours (e.g., `http://cloford.com/resources/colours/500col.htm`).

9.4 Using RATs for rule based classifications.

To use a RAT to undertake a rule based object oriented classification the first step is to create a set of image clumps (e.g., through segmentation see appendix A section A.3), then the rows of the attribute table need populating with information (e.g., see appendix A section A.4). Once these steps have been completed then a rule base using the numpy where statements can be created and executed, resulting in a similar process as the eCognition software.

9.4.1 Developing a rule base

This is a similar process to developing a rule based classification within eCognition, where the clumps are the segments/objects and the columns are the features, such as mean, standard deviation etc.

Using 'where' statements, similar to those used within the rule based classification of the image pixels, the clumps can be classified. The example, shown below, illustrates the classification of the Landcover classification system (LCCS) levels 1 to 3. Where the classes are represented by string names within the class names column within the attribute table.

The classification is undertaken using three dates of WorldView2 imagery captured over Cors Fochno, in Wales UK. A segmentation has been provided and the segments have been populated with mean reflectance values from the three WorldView2 images, the DTM minimum and maximum and the CHM height.

```
1 #!/usr/bin/env python
2
```

```
3  # Import the system library
4  import sys
5  # Import the rat modele from RIOS

233 
234     # Check that the input parameter has been specified.
235     if args.input == None:
236         # Print an error message if not and exit.
237         print "Error: No input image file provided."
238         sys.exit()
239 
240     # Run the classification
241     runClassification(args.input)
```

Run the Classification

To run the classification use the following command:

```
python LCCS_L13_Classification.py -i WV2_525N040W_2m_segments.kea
```

Colour the classification

Following the classification, the clusters need to be coloured and the script for this shown below. The previous example of adding a colour table is not suited to this case as colours are being applied to the individual segments based on their class allocation.

```
#!/usr/bin/env python

Chapter 10

Golden Plover Population Model

10.1 Introduction

The aim of this work sheet is to develop a populate model for a bird, called the Golden Plover.

10.2 Model Output

The model is required to output the total population of the birds for each year and the number of bird, eggs, fledgling and the number of fledglings which are a year old. Providing an option to export the results as a plot should also be provided.

10.3 Reading Parameters

To allow a user to parameterise the model a parameter card, such as the one shown below, needs to be provided.

```
numOfYears=20
initalAdultPairPop=15
winterSurvivalRate=0.66
averageEggsPerPair=3.64
averageFledgelingsPerPair=3.2
predatorControl=False
numOfFledgelings=14
numOfFledgelingsYearOld=8
fledgelingsSurvivePredatorsCtrl=0.75
fledgelingsSurvivePredatorsNoCtrl=0.18
```

```
#!/usr/bin/env python

# Import the system library
import sys
# Import the python Argument parser
import argparse
# Import the maths library
import math as math

# A class for the golden plover population model
class GoldenPloverPopModel (object):

    # A function to parse the input parameters file.
    def parseParameterFile(self, inputFile):
        # A string to store the input parameters to
        # be outputted in the output file.
        paramsStr = "## Input Parameters to the model.\n"
        # Open the input parameter file.
        parameterFile = open(inputFile, 'r')
        # Create a dictionary object to store the
        # input parameters.
        params = dict()

RSGISLib

A.1 Introduction to RSGISLib

The remote sensing and GIS software library (RSGISLib) was developed at Aberystwyth University by Pete Bunting and Daniel Clewley. Development started in April 2008 and has been actively maintained and added to ever since. For more information see `http://www.rsgislib.org`.

A.2 Using RSGISLib

RSGISLib has a command line user interface where the main commands you will be using are:

rsgisexe - the main command to execute scripts

rsgislibxmllist - a command to list all the available commands within the library

(there are over 300!!)

rsgislibcmdxml.py - a command to allow script templates to be populated with file paths and names.

rsgislibvarsxml.py - a command to input variable values into a template script.

A.2.1 The RSGISLib XML Interface

XML Basics

RSGISLib is parameterised through the use of an XML script. XML stands for Extensible Markup Language.

Extensible - XML is extensible. It lets you define your own tags, the order in which they occur, and how they should be processed or displayed. Another way to think about extensibility is to consider that XML allows all of us to extend our notion of what a document is: it can be a file that lives on a file server, or it can be a transient piece of data that flows between two computer systems.

Markup - The most recognizable feature of XML is its tags, or elements (to be more accurate).

Language - XML is a language that's very similar to HTML. It's much more flexible than HTML because it allows you to create your own custom tags. However, it's important to realize that XML is not just a language. XML is a meta-language: a language that allows us to create or define other languages. For example, with XML we can create other languages, such as RSS,

MathML (a mathematical markup language).

```
<parent_element>
    <some_information>
    </some_information>
    <some_information name="some data" value="some other data" />
</parent_element>
```

XML is made up of opening and closing elements, where the hierarchy of the elements provides meaning and structure to the information stored. Therefore, every element has an opening and closing element. This can be defined in two ways; firstly with two tags, where the opening tag is just enclosed with angled brackets ($< tag >$) and the closing tag contains a backslash and angled brackets $< /tag >$. Using this method further tags for data can be stored between the two tags, providing structure as shown above. The second method uses just a single tag with an ending backslash ($< tag/ >$). This second method is used when no data or further tags are to be defined below current element.

```
<element></element>
```

```
<element/>
```

Escape Characters

As with all computing languages there are certain characters which have specific meanings and therefore an escape character needs to be used if these characters are required within the input.

& - &

′ - '

" - "

< - <

> - >

= - =

```
<element attribute="&apos;hello&apos;"/>
    <element>
        1 is &lt; 100
   </element>
<element attribute="&quot;world&quot;"/>
```

Commenting

To add comments to XML code and temporally comment out parts of your XML script you need to use the XML commenting syntax as show below.

```
<!-- Some useful comment -->
<parent_element>
    <some_information>
    </some_information>
    <!-- This is some really useful information in this comment -->
    <some_information name="some data" value="some other data" />
</parent_element>
```

All parts of the document between the opening and closing comment tags will be ignored by the parser.

RSGISLib XML

For parameterisation of the rsgisexe application you will need to create an XML file in the correct format, which the RSGISLib executable understands, while adhering

to the rules of XML outlined above. The basis for the RSGISLib XML is to provide a list of commands. Therefore, the XML has the following structure:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!--
    Description:
        XML File for execution within RSGISLib
    Created by **ME** on Wed Nov 28 15:53:41 2012.
    Copyright (c) 2012 **Organisation**. All rights reserved.
-->

<rsgis:commands xmlns:rsgis="http://www.rsgislib.org/xml/">

  <!-- ENTER YOUR XML HERE -->
  <rsgis:command algor="name" option="algor_option" attr1="foo"
                                                    attr2="bar">
    <rsgis:data attribute="blob" />
  </rsgis:command>
  <rsgis:command algor="algor_name" option="algorithm_option"
                                                    attr="data"/>

</rsgis:commands>
```

Where all the input parameters are defined using element attributes and each algorithm and option have their own set of attributes to be specified. Within the XML file imported into rsgisexe multiple command elements can be specified and they will all be executed in the order specified in the XML file. Therefore, a sequence of events can be specified and executed without any further interaction.

A.3 Segmentation

The segmentation algorithm (**?**) is based on generating spectrally similar units with a minimum object size.

The algorithm consists of a number of steps

1. Select image bands and stack images
2. Stretch image data
3. Find unique cluster within feature space (KMeans)
4. Assign pixels to clusters
5. Clump the image
6. Eliminate small segments

The KMeans clusters takes just a single image where all the bands are used as input so if multiple images are required to be inputted then they need to be stacked and the bands which are to be used selected. As a Euclidean distance is used within the feature space the image is stretched such that all the pixel values are within the same range (i.e., 0–255).

A clustering algorithm is then used to identify the unique colours within the image, in this case a KMeans clustering is used but other clustering algorithms could also be used instead. The image pixels are then assigned to the clusters (classifying the image) and the image clumped to find the connected regions of the image.

The final step is an iterative elimination of the small segments, starting with the single pixels and going up to the maximum size of the segments specified by the user.

Therefore, there are two key parameters within the algorithm:

1. the number of cluster centres identified by the KMeans clustering
2. the minimum size of the segments

A.3.1 XML Code

```
<rsgis:command algor="imageutils" option="stretch" image="$FILEPATH"
               output="$PATH/$FILENAME_stretched.kea" ignorezeros="yes"
               stretch="LinearStdDev" stddev="2" format="KEA" />

<rsgis:command algor="imagecalc" option="bandmaths" output="$PATH/$FILENAME_mask.kea"
               format="KEA" expression="b1==0?0:1" >
        <rsgis:variable name="b1" image="$FILEPATH" band="1" />
</rsgis:command>

<rsgis:command algor="imageutils" option="mask"
               image="$PATH/$FILENAME_stretched.kea"
               mask="$PATH/$FILENAME_mask.kea"
               output="$PATH/$FILENAME_stretched_masked.kea"
               maskvalue="0" outputvalue="0" format="KEA" />

<rsgis:command algor="commandline" option="execute"
               command="rm $PATH/$FILENAME_mask.kea" />
<rsgis:command algor="commandline" option="execute"
               command="rm $PATH/$FILENAME_stretched.kea" />

<rsgis:command algor="imagecalc" option="kmeanscentres"
               image="$PATH/$FILENAME_stretched_masked.kea"
               output="$PATH/$FILENAME_clusters" numclusters="60" maxiterations="200"
```

```
24                 degreeofchange="0.25" subsample="1" initmethod="diagonal_range_attach" />
25
26 <rsgis:command algor="segmentation" option="labelsfromclusters"
27                 image="$PATH/$FILENAME_stretched_masked.kea"
28                 output="$PATH/$FILENAME_clusters.kea"
29                 clusters="$PATH/$FILENAME_clusters.gmtxt"
30                 ignorezeros="yes" format="KEA" proj="IMAGE" />
31
32 <rsgis:command algor="segmentation" option="elimsinglepxls"
33                 image="$PATH/$FILENAME_stretched_masked.kea"
34                 clumps="$PATH/$FILENAME_clusters.kea"
35                 temp="$PATH/$FILENAME_clusters_singlepxls_tmp.kea"
36                 output="$PATH/$FILENAME_clusters_nosinglepxls.kea"
37                 ignorezeros="yes" format="KEA" proj="IMAGE" />
38
39 <rsgis:command algor="commandline" option="execute"
40                 command="rm $PATH/$FILENAME_clusters.kea" />
41 <rsgis:command algor="commandline" option="execute"
42                 command="rm $PATH/$FILENAME_clusters_singlepxls_tmp.kea" />
43
44 <rsgis:command algor="segmentation" option="clump"
45                 image="$PATH/$FILENAME_clusters_nosinglepxls.kea"
46                 output="$PATH/$FILENAME_clumps.kea" nodata="0"
47                 format="KEA" inmemory="no" proj="IMAGE" />
48
49 <rsgis:command algor="commandline" option="execute"
50                 command="rm $PATH/$FILENAME_clusters_nosinglepxls.kea" />
51
52 <rsgis:command algor="segmentation" option="rmsmallclumpsstepwise"
53                 image="$PATH/$FILENAME_stretched_masked.kea"
54                 clumps="$PATH/$FILENAME_clumps.kea"
```

```
55                output="$PATH/$FILENAME_clumps_elim.kea"
56                minsize="50" maxspectraldist="200000"
57                format="KEA" inmemory="no" proj="IMAGE" />
58
59  <rsgis:command algor="commandline" option="execute"
60                command="rm $PATH/$FILENAME_stretched_masked.kea" />
61  <rsgis:command algor="commandline" option="execute"
62                command="rm $PATH/$FILENAME_clumps.kea" />
63
64  <rsgis:command algor="segmentation" option="relabelclumps"
65                image="$PATH/$FILENAME_clumps_elim.kea"
66                output="$PATH/$FILENAME_clumps_elim_final.kea"
67                format="KEA" inmemory="no" proj="IMAGE" />
68
69  <rsgis:command algor="commandline" option="execute"
70                command="rm $PATH/$FILENAME_clumps_elim.kea" />
71
72  <rsgis:command algor="segmentation" option="meanimg"
73                image="$FILEPATH" clumps="$PATH/$FILENAME_clumps_elim_final.kea"
74                output="$PATH/$FILENAME_clumps_elim_mean.kea"
75                format="KEA" inmemory="no" proj="IMAGE" />
76
77  <rsgis:command algor="imageutils" option="popimgstats"
78                image="$PATH/$FILENAME_clumps_elim_mean.kea" ignore="0" pyramids="yes" />
```

To use the script provided you need to use the rsgislibxml.py command which replaces the $FILEPATH with the file path of the input image (found by rsgislibxml.py within the input directory) $PATH with the provided directory path and $FILENAME with the name of the input file. An example of this command is given below:

```
rsgislibxml.py -i RunSegmentationTemplate.xml \
               -o Segmentation.xml -p ./Segments \
               -d ./Data/ -e .kea -r no -t single
```

Once the command above has been executed then the segmentation can be run using the rsgisexe command:

```
rsgisexe -x Segmentation.xml
```

The resulting segmentation will have produced 3 output files

1. *clusters.gmtxt – Cluster centres.
2. *clumps_elim_final.kea – Segment clumps.
3. *clumps_elim_mean.kea – Mean colour image using segments.

Following the segmentation the it is recommend that you make sure that the clumps file is defined as a thematic file, as demonstrated in the following piece of python:

```
#!/usr/bin/env python

import sys
from osgeo import gdal

ds = gdal.Open(sys.argv[1], gdal.GA_Update)
for bandnum in range(ds.RasterCount):
    band = ds.GetRasterBand(bandnum + 1)
    band.SetMetadataItem('LAYER_TYPE', 'thematic')
```

Finally, use the gdalcalcstats command to populate the image with an attribute table, histogram and colour table (set -ignore 0 as 0 is the background no data value).

```
setthematic.py L7ETM_530N035W_clumps_elim_final.kea
gdalcalcstats L7ETM_530N035W_clumps_elim_final.kea -ignore 0
```

A.4 Populating Segments

To populate the segments with statistics (i.e., Mean for each spectral band) there is a command with the rastergis part of the RSGISLib software. Examples of this are shown within the XML code below, note the text given for each band is the names of the output columns.

```
<?xml version="1.0" encoding="UTF-8" ?>
<!--
    Description:
        XML File for execution within RSGISLib
    Created by **ME** on Thu Mar 21 09:25:21 2013.
    Copyright (c) 2013 **Organisation**. All rights reserved.
-->

<rsgis:commands xmlns:rsgis="http://www.rsgislib.org/xml/">

    <rsgis:command algor="rastergis" option="popattributestats"
                   clumps="L7ETM_530N035W_Classification.kea"
                   input="L7ETM_530N035W_20100417_AtCor_osgb_masked.kea" >
        <rsgis:band band="1" mean="MayBlue" stddev="MaySDBlue" />
        <rsgis:band band="2" mean="MayGreen" stddev="MaySDGreen" />
        <rsgis:band band="3" mean="MayRed" stddev="MaySDRed" />
        <rsgis:band band="4" mean="MayNIR" stddev="MaySDNIR" />
        <rsgis:band band="5" mean="MaySWIR1" stddev="MaySDSWIR1" />
        <rsgis:band band="6" mean="MaySWIR2" stddev="MaySDSWIR2" />
    </rsgis:command>
```

```
21
22      <rsgis:command algor="rastergis" option="popattributestats"
23                     clumps="L7ETM_530N035W_Classification.kea"
24                     input="L7ETM_530N035W_20100620_AtCor_osgb_masked.kea" >
25          <rsgis:band band="1" mean="JuneBlue" stddev="JuneSDBlue" />
26          <rsgis:band band="2" mean="JuneGreen" stddev="JuneSDGreen" />
27          <rsgis:band band="3" mean="JuneRed" stddev="JuneSDRed" />
28          <rsgis:band band="4" mean="JuneNIR" stddev="JuneSDNIR" />
29          <rsgis:band band="5" mean="JuneSWIR1" stddev="JuneSDSWIR1" />
30          <rsgis:band band="6" mean="JuneSWIR2" stddev="JuneSDSWIR2" />
31      </rsgis:command>
32
33      <rsgis:command algor="rastergis" option="popattributestats"
34                     clumps="L7ETM_530N035W_Classification.kea"
35                     input="Nant_y_Arian_DEM_30m.kea" >
36          <rsgis:band band="1" min="MinDEM" mean="MaxDEM"
37                               mean="MeanDEM" stddev="StdDevDEM" />
38      </rsgis:command>
39
40  </rsgis:commands>
```

If you are going to use a indices and other derived information within your classification it is quite often a good idea to set up a python script to calculate those indices and write them back to the image rather than over complicating your classification script. An example of this is shown below.

```
1  #!/usr/bin/env python
2
3  import sys
4  from rios import rat
5  import numpy
```

```
6  import osgeo.gdal as gdal
7
8
9  #Input file.
10 fname = "L7ETM_530N035W_Classification.kea"
11 ratDataset = gdal.Open( fname, gdal.GA_Update )
12
13 print "Import Columns."
14 MayBlue = rat.readColumn(ratDataset, "MayBlue")
15 MayGreen = rat.readColumn(ratDataset, "MayGreen")
16 MayRed = rat.readColumn(ratDataset, "MayRed")
17 MayNIR = rat.readColumn(ratDataset, "MayNIR")
18 MaySWIR1 = rat.readColumn(ratDataset, "MaySWIR1")
19 MaySWIR2 = rat.readColumn(ratDataset, "MaySWIR2")
20
21 JuneBlue = rat.readColumn(ratDataset, "JuneBlue")
22 JuneGreen = rat.readColumn(ratDataset, "JuneGreen")
23 JuneRed = rat.readColumn(ratDataset, "JuneRed")
24 JuneNIR = rat.readColumn(ratDataset, "JuneNIR")
25 JuneSWIR1 = rat.readColumn(ratDataset, "JuneSWIR1")
26 JuneSWIR2 = rat.readColumn(ratDataset, "JuneSWIR2")
27
28 MeanDEM = rat.readColumn(ratDataset, "MeanDEM")
29
30 MayNIR.astype(numpy.float32)
31 MayRed.astype(numpy.float32)
32 JuneNIR.astype(numpy.float32)
33 JuneRed.astype(numpy.float32)
34 MayBlue.astype(numpy.float32)
35 JuneBlue.astype(numpy.float32)
36
```

```
37 print "Calculate Indices."
38 MayNDVI = (MayNIR - MayRed) / (MayNIR + MayRed)
39 JuneNDVI = (JuneNIR - JuneRed) / (JuneNIR + JuneRed)
40
41 MayWBI = MayBlue/MayNIR
42 JuneWBI = JuneBlue/JuneNIR
43
44 rat.writeColumn(ratDataset, "MayNDVI", MayNDVI)
45 rat.writeColumn(ratDataset, "JuneNDVI", JuneNDVI)
46 rat.writeColumn(ratDataset, "MayWBI", MayWBI)
47 rat.writeColumn(ratDataset, "JuneWBI", JuneWBI)
```
