Part I.

Installation and Basic Use

1. About Galacticus

Galacticus is a semi-analytic model of galaxy formation. It solves equations describing how galaxies evolve in a merging hierarchy of dark matter halos in a cold dark matter universe. Galacticus has much in common with other semi-analytic models, such as the range of physical processes included and the type of quantities that it can predict.

In designing Galacticus our main goal was to make the code flexible, modular and easily extensible. Much greater priority was placed on making the code easy to use and modify than on making it fast. We believe that a modular and extensible nature is crucial as galaxy formation is an evolving science. In particular, key design features are:

Extensible methods for all functions: Essentially all functions within Galacticus are designed to be extensible following an Object Oriented methodology, meaning that you can write your own version and insert it into Galacticus easily. For example, suppose you want to use an improved functional form for the cold dark matter (CDM) halo mass function. You would simply write a new `haloMassFunction` class that computes this mass function, decorate it with a short directive (see §16.1) which explains to the build system how to insert connect this class into Galacticus. A recompile of the code will then incorporate your new function.

Extensible components for tree nodes: The basic structure in Galacticus is a merger tree, which consists of a linked tree of nodes which have various properties. Galacticus works by evolving the nodes forwards in time subject to a collection of differential equations and other rules. Each node can contains an arbitrary number of *components*. A component may be a dark matter halo, a galactic disk, a black hole etc. Each component may have an arbitrary number of *properties* (some of which may be evolving, others of which can be fixed). Galacticus makes it easy to add additional components. For example, suppose you wanted to add a "stellar halo" components (consisting of stars stripped from satellite galaxies). To do this, you would write a module which specifies the following for this component:

- Properties (their names, types, and ranks);
- Functions describing the differential equations which govern the evolution of the properties;
- Functions describing how the component responds to various events (e.g. the node becoming a satellite, a galaxy-galaxy merger, etc.);
- "Pipes" which allow for flows of mass/energy/etc. from one component to another.

Short directives embedded in this module explain to the Galacticus build system how to incorporate the new component. A recompile will then build your new component into Galacticus. Typically, a new component can be created quickly by copying an existing one and modifying it as necessary. Furthermore, multiple implementations of a component are allowed. For example, Galacticus contains a component which tracks the scale length of the dark matter halo. You could add a new component which additionally tracks the axis ratios of the (now triaxial) halo. A simple input parameter then allows you to select which implementation will be used in a given run.

Centralized ODE solver: Galacticus evolves nodes in merger trees by calling an ODE solver which integrates forwards in time to solve for the evolution of the properties of each component in a node. This means that you do not need to provide explicit solutions for ODEs (in many cases such

solutions are not available anyway) and timestepping is automatically handled to achieve a specified level of precision. The ODE solver allows for the evolution to be interrupted. A component may trigger an interrupt at any time and may do so for a number of reasons. A typical use is to actually create a component within a given node—for example when gas first begins to cool and inflow in a node the disk component must be created. Other uses include interrupting evolution when a merging event occurs.

1.0.1. Getting Galacticus

Downloads and installation instructions can be found at https://bitbucket.org/galacticusdev/galacticus/wiki/Home.

2. Running Galacticus

2.1. Configuration File

The file `galacticusConfig.xml`, is present, is used to configure Galacticus and provide useful information. It should have the following structure:

```
<config>
  <contact>
    <name>My Name</name>
    <email>me@ivory.towers.edu</email>
  </contact>
  <email>
    <host>
      <name>myComputerHostName</name>
      <method>smtp</method>
      <host>smtp-server.ivory.towers.edu</host>
      <user>myUserName</user>
      <passwordFrom>kdewallet</passwordFrom>
    </host>
    <host>
      <name>default</name>
      <method>sendmail</method>
    </host>
  </email>
</config>
```

The name and e-mail address in the `contact` section will be stored in any Galacticus models run—this helps track the provenance of the model. The `email` section determines how e-mail will be sent. Within this section, you can place one or more `host` elements, the `name` element of which specifies the host name of the computer to which these rules apply (the `default` host is used if no other match is found). For each host, the `method` element specifies how e-mail should be sent, either by `sendmail` or via `smtp`. For SMTP transport (which currently supports SSL connections only), you must specify the `host` SMTP server, `user` name. The `passwordFrom` element specifies how the password for the SMTP log in should be obtained. If set to `input` then the user will be prompted for the password as needed. Alternatively, if you use the KDE desktop and the KDEWallet password manager, setting `passwordFrom` to `kdewallet` will cause the password to be stored in the KDE wallet and retrieved from there subsequently.

2.2. Parameter Files

Galacticus requires a file of parameters to be given as a command line argument. The parameter file is an XML file (which makes it easy to manipulate and construct these files from within many languages, e.g. Perl) with the following structure:

```
 <parameters>
```

```
  <version>0.9.4</version>
  <formatVersion>2</formatVersion>
  <parameter1Name value= "parameter1Value" />
  <parameter2Name>
    <value>parameter2Value</value>
  </parameter2Name>
  <parameter3Name value= "parameter3Value" >
     <subParameter1Name value= "subParameter1Value" />
     <subParameter2Name value= "subParameter2Value" />
     .
     .
     .
  </parameter3Name>
  .
  .
  .
  <parameter4Name value= "parameter4Value" id="myRefParam" >
     <subParameter1Name value= "subParameter1Value" />
     <subParameter2Name value= "subParameter2Value" />
     .
     .
     .
  </parameter3Name>
  .
  .
  .
  <parameter4Name idRef="myRefParam"/>
  .
  .
  .
</parameters>
```

Each named element must have a `value` attribute (preferred), or else contains a value element, which contains desired value respectively. The value can be a number, word(s) or an array of space-separated numbers or words. Parameters are used to control the values of numerical parameters and also to select methods and other options. If a parameter is not specified in the file a default value (hard coded into Galacticus) will be used instead. The default values have been chosen to produce a realistic model of galaxy formation, but may change as Galacticus evolves. Parameters may have sub-parameters embedded within them, as in the example above.

Sub-parameters are used in object composition within Galacticus. For example, the following would specify that linear growth of cosmological large scale structure should be modeled using the `simple` method:

```
<linearGrowthMethod value="simple">
  <cosmologyParametersMethod value="simple">
    <HubbleConstant   value="70.0" />
    <OmegaMatter      value="0.31"  />
    <OmegaDarkEnergy  value="0.69"  />
    <OmegaBaryon      value="0.045"/>
    <temperatureCMB   value="2.725"/>
  </cosmologyParametersMethod>
```

```
    <cosmologyFunctionsMethod value="matterLambda"/>
  </linearGrowthMethod>
```

The linear growth function object requires knowledge about the cosmological parameters and model. In the above, we specify this explicitly by including a definition of the cosmological parameter object and cosmological functions object that our linear growth function object should use. Note that the cosmological functions object also requires knowledge of the cosmological parameters. When the `cosmologyFunctionsMethod` object is built from the above definition it will first check for a cosmological parameters object defined in its own subparameters. Since it does not find one in this instance it will check for a cosmological parameters definition in its parent object (the `linearGrowthMethod` element) and, in this case, will use that definition. If no definition were to be found in any parent element, a default set of cosmological parameters would be used instead[1].

Parameters can also be defined with an "`id`" attribute. Such parameters are targets for pointers elsewhere in the file, and as such are inactive (i.e. they will be ignored by Galacticus except as targets for pointers). A pointer to a target is created by specifying an element with the same parameter name and an "`idRef`" element with a value equal to that of the `id` element of the target. The pointer then acts as a regular parameter, adopting the value and subparameters of the target. Targets can be targetted by multiple pointers. This allows for a single object to be shared between multiple other objects.

The optional `version` element specifies which version of Galacticus this parameter file is intended for. The optional `formatVersion` element specifies the parameter file version number (the current standard for parameter files is version 2). While optional, these elements can be useful when migrating parameter files between versions of Galacticus (see §6.5).

All parameter values (both those specified in this file and those set to default) used during a Galacticus run are output to the `Parameters` group within the Galacticus output file. The script `scripts/aux/Extract_Parameter_File.pl` will, if given a Galacticus output file, extract the parameters from it and output them into an XML file suitable for re-input into Galacticus. If parameters are present in the parameter file which do not match any known parameter in Galacticus then a warning message, listing all unknown parameters, will be given when Galacticus is run. Note that this will *not* prevent Galacticus from running—sometimes it is convenient to include parameters which are not used by Galacticus, but which might be used by some other code.

2.2.1. Validating Parameter Files

A script, `scripts/aux/validateParameters.pl`, is provided to validate parameter files and thereby ensure that they are consistent with Galacticus's expectations and requirements. To use simply execute:

```
scripts/aux/validateParameters.pl myParameters.xml
```

No output (and an exit value of 0) indicates a valid parameter file. Invalid parameter files will result in an exit value other than 0 and will produce error messages that should help to track down the problem with the file.

2.2.2. Generating Parameter Files

Some scripts are provided which assist in the generation of parameter files. These are located in the `scripts/parameters/` folder and are detailed below:

[1] This approach allows a direct connection to be made between the structure of the input parameter XML file and the internal object hierarchy used by Galacticus, allowing very fine-grained control over the composition of Galacticus functionality. In particular it permits easy construction of objects which work by modifying results from other objects, such as the `schneider2015` model for dark matter halo concentrations (§12.11.3).

`cosmologicalParametersMonteCarlo.pl` This script will generate a set of cosmological parameters drawn at random from the WMAP-9 constraints Hinshaw et al. [2012]. It uses the covariance matrix (currently defined in `data/Cosmological_Parameters_WMAP-9.xml`) to produce correlated random variables[2]. The generated parameters are printed to standard output as Galacticus-compatible XML.

2.3. Running Galacticus

Galacticus is running using

```
Galacticus.exe [<parameterFile>]
```

where `parameterFile` is the name of the file containing a list of parameter values for Galacticus. Galacticus will display messages indicating its progress as it runs (the verbosity can be controlled with the `verbosityLevel` parameter). Usually, the Galacticus executable should be invoked from the directory in which it was built. However, you can choose to set the environment variable `GALACTICUS_ROOT_V091` to the full path to the build directory, in which case the Galacticus executable can be invoked from anywhere and will access all required files and scripts relative to this path. This can allow multiple users to all make use of the same Galacticus install.

2.3.1. Writing Data To a Temporary File

When running Galacticus on a compute cluster it is often advantageous to have output written to a local scratch disk during run time and only moved to networked storage after the run is complete. (Otherwise, Galacticus will perform many small writes to networked storage which can result in extremely slow run times.) To do this, simply set the parameter `[galacticusOutputScratchFileName]` to the full path of a file to write to on local scratch space. During the run, data will be written to this file. After the run is finished, Galacticus will move this file to its permanent location as specified by the parameter `[galacticusOutputFileName]`.

2.3.2. Restarting A Crashed Run

If Galacticus crashes, it can be useful to restart the calculation from just prior to the crash to speed the debugging process. Galacticus has functionality to store and retrieve the internal state of any modules and to recover this to permit such restarting. Currently, this is implemented with the `build` and `read` methods of merger tree construction, such that the internal state is stored prior to commencing the building or reading of each tree, thereby allowing a calculation to be restarted with the tree that crashed. More general store/retrieve behavior is planned for future releases.

To cause Galacticus to periodically store its internal state include the following input parameter:

```
<stateFileRoot value="galacticusState" />
```

This will cause the internal state to be stored to files `galacticusState.state` and `galacticusState.fgsl.state` prior to commencing building each merger tree. Should a tree crash then replace this input parameter with:

```
<stateRetrieveFileRoot           value="galacticusState" />
<mergerTreeBuildTreesBeginAtTree value="N"               />
```

[2]Note that this does not capture the full details of the correlations between parameters, since it uses just the covariance matrix. For a more accurate calculation the full Monte Carlo Markov Chains used in the WMAP-9 parameter fitting should be used instead.

where `N` is the number of the tree that crashed. This will cause calculations to begin with tree `N` and for the internal state to be recovered from the above mentioned files. The resulting tree and all galaxy formation calculations should therefore proceed just as in the original run (and so create the same crash condition).

OpenMP

When running a model in parallel using OpenMP, a separate state file will be written for each thread, with the thread number appended to the end of each state file name. For debugging purposes, it is suggested that a crashed OpenMP run be restarted using just a single thread. To do this, change the appended thread number on the state files corresponding to the thread which crashed to 0 such that they will be used by the single thread when the run is restarted.

2.3.3. Running Grids of Models

You can easily write your own scripts to generate parameter files and run Galacticus on these files. An example of such a script is `scripts/aux/launch.pl`. This script will loop over a sequence of parameter values, generate appropriate parameter files, run Galacticus using those parameters and analyze the results. This script currently supports running of Galacticus on a local machine, via a PBS queue (as multiple jobs or a single job), or on a Condor cluster. To run the script simply enter:

```
./scripts/aux/launch.pl <runFile>
```

This will launch a single instance of the script. Multiple instances can be launched and will share the work load (i.e. they will not attempt to run a model which another instance is already running or has finished). If multiple instances are to be launched on multiple machines a command line option to `launch.pl` can be used to ensure that they do not duplicate work. Adding `-instance 2:4` for example will tell the script to run only the second model from each block of four models it finds. Launching for `launch.pl` scripts on four different machines with `-instance 1:4`, `-instance 2:4`, `-instance 3:4` and `-instance 4:4` will then divide the models between those machines.

The `runFile` is an XML file with the following structure:

```
<parameterGrid>
 <modelRootDirectory>models.new</modelRootDirectory>
 <baseParameters>newBestParametersQuick.xml</baseParameters>
 <compressModels>no</compressModels>
 <splitModels>4</splitModels>

 <launchMethod>pbs</launchMethod>

  <local>
   <threadCount>3</threadCount>
   <ompThreads>4</ompThreads>
  </local>

 <condor>
  <galacticusDirectory>/home/condor/Galacticus/v0.9.3</galacticusDirectory>
  <universe>vanilla</universe>
  <environment>LD_LIBRARY_PATH=/usr/lib:/usr/lib64:/usr/local/lib</environment>
  <requirement>Memory &gt;= 1000 &amp;&amp; Memory &lt; 2000</requirement>
  <transferFile>{PWD}/myFile.data</transferFile>
```

```
 <wholeMachine>true</wholeMachine>
 <postSubmitSleepDuration>5</postSubmitSleepDuration>
 <jobWaitSleepDuration>10</jobWaitSleepDuration>
</condor>

<pbs>
 <scratchPath>/scratch/me</scratchPath>
 <wallTime>48:00:00</wallTime>
 <memory>3gb</memory>
 <ompThreads>8</ompThreads>
 <queue>standard</queue>
 <maxJobsInQueue>10</maxJobsInQueue>
 <mpiLaunch>yes</mpiLaunch>
 <mpiRun>/opt/openmpi/bin/mpirun</mpiRun>
 <environment>LD_LIBRARY_PATH=/home/me/software/Galacticus/Tools/lib64:$LD_LIBRARY_PATH</environment>
 <postSubmitSleepDuration>10</postSubmitSleepDuration>
 <jobWaitSleepDuration>60</jobWaitSleepDuration>
</pbs>

<monolithicPBS>
 <mpiLaunch>yes</mpiLaunch>
 <nodes>1</nodes>
 <threadsPerNode>12</threadsPerNode>
 <ompThreads>6</ompThreads>
 <jobWaitSleepDuration>60</jobWaitSleepDuration>
 <analyze>no</analyze>
 <environment>LD_LIBRARY_PATH=/home/me/software/Galacticus/Tools/lib64:$LD_LIBRARY_PATH</environment>
 <includePath>/my/include/path</includePath>
 <libraryPath>/opt/sgi/mpt/mpt-2.04/lib</libraryPath>
 <shell>csh</shell>
 <pbsCommand>source /usr/share/modules/init/csh</pbsCommand>
 <pbsCommand>module load mpi-sgi/2.04_64</pbsCommand>
</monolithicPBS>

<parameters>
 <label>modelLabel</label>
 <stabilityThresholdStellar value="1.1"/>
 <stabilityThresholdStellar value="0.9"/>
</parameters>

<parameters>
 <starFormationFeedbackDisksMethod value="powerLaw">
  <exponent value="2.5"/>
  <exponent value="3.0"/>
 </starFormationFeedbackDisksMethod>
 <starFormationFeedbackDisksMethod value="creasey2012"/>
</parameters>

<parameters>
```

```
  <imfSelectionMethod value="fixed">
    <imfSelectionFixed value="Chabrier" parameterLevel="top"/>
    <imfSelectionFixed value="Salpeter" parameterLevel="top"/>
  </imfSelectionMethod>
  <imfSelectionMethod value="diskSpheroid">
    <imfSelectionDisk     value="Chabrier"  parameterLevel="top"/>
    <imfSelectionSpheroid value="Kennicutt" parameterLevel="top"/>
  </imfSelectionMethod>
 </parameters>

 <parameters>
   <coolingFunctionMethod value="summation">
     <coolingFunctionMethod value="atomicCIECloudy"             iterable="no"/>
     <coolingFunctionMethod value="CMBCompton"                  iterable="no"/>
     <coolingFunctionMethod value="molecularHydrogenGalliPalla" iterable="no"/>
   </coolingFunctionMethod>
 </parameters>

</parameterGrid>
```

Each `parameters` block contains a list of parameters following the format used in standard Galacticus parameter files, with the difference that each parameter can appear multiple times, each time with a different `value` attribute, as is the case for `stabilityThresholdStellar` in the first `parameters` element in the above. A model will be run for all possible combinations of these values. For nested parameters with multiple values, all possible values of these parameters will be looped over when, and only when, the appropriate value of the containing parameter is being used. For example, in the second `parameters` element in the above example, models will be run with subparameter `[exponent]=2.5` and `3.5` for the `starFormationFeedbackDisksMethod` element only when `[starFormationFeedbackDisksMethod]=powerLaw` and not when `[starFormationFeedbackDisksMethod]=creasey2012`. It is also possible to specify that subparameter should be promoted to the top-level of the parameter file. In the third `parameters` element in the above example, `imfSelectionFixed` will take on values of `Chabrier` and `Salpeter` only when `imfSelectionMethod=fixed`, and the `imfSelectionFixed` element will be promoted from a subparameter of `imfSelectionMethod` to the top-level of the parameter file due to the presence of the `parameterLevel="top"` attribute. Finally in some cases a parameter which appears multiple times is not to be iterated over. In the fourth `parameters` element in the above example, this is the case for the `coolingFunctionMethod` subparameters. The addition of an `iterable="no"` attribute specifies that these parameters are not to be iterated over, but simply left as they are.

Some variables, which are expanded at run time, are available. These include:

`%%galacticusOutputPath%%` This will be expanded to the output path of a model. Useful for specifying paths for any additional output.

By default, each model is output into a sequentially numbered directory within the `./models` directory. By default, these directories have the prefix `galacticus`. This can be changed by including a `label` element inside a `parameters` block, in which case the content of the `label` element will be used as the prefix. This root directory can be modfified by the optional `modelRootDirectory` element. Additionally, a set of base parameters can be read from a file specified by the `baseParameters` file—these will be read before each model is run and before any variations in parameters for the specific model are applied. As such, it defines the default model around which parameter variations occur. Additional options that may be present in the file (as elements within the `parameterGrid` element) are:

`doAnalysis` If set to "no" then no analysis scripts will be run on completed models, otherwise, they will be. Optionally, the analysis script to run can be specified via the `analysisScript` element (see §2.3.4);

`emailReport` If set to "yes" a report will be e-mailed to the address specified in `galacticusOptions.xml` when a model fails. Otherwise, the report will be written to standard output instead.

`compressModels` If "no" then models are not compressed after being run. Otherwise, the contents of the model output directory will be compressed using `bzip2`.

`splitModels` If set to an integer larger than 1, each Galacticus model will be split into that number of jobs, and those jobs will be launched (using the selected method) independently. Once finished, the outputs from these split models will be merged back into a single model. This allows, for example, effectively distributing a single Galacticus model over multiple nodes of a PBS cluster.

The method by which to launch jobs must be specified in the `launchMethod` element. Currently available options are:

`local` The models will be run on the local machine. Two additional options can be specified within a `local` XML block:

- `threadCount` The number of individual model threads to be launched.
- `ompThreads` The number of OpenMP threads to be used by each model.

`pbs` Jobs will be submitted to a `PBS` batch queue system. The following options are available and can be specified within a `pbs` XML block:

- `scratchPath` An optional path to which the model output will be written at run time. At the completion of each run, the data will be transferred to the usual output location. This is useful to avoid network I/O during run time;
- `wallTime` A limit on the wall time allowed for each model (optional);
- `memory` A limit on the memory allowed for each model (optional);
- `ompThreads` The number of OpenMP threads to use for each model (optional). This is used to request an appropriate number of processors per node;
- `queue` The name of the queue to submit the jobs to (optional);
- `maxJobsInQueue` The maximum number of jobs to place in the queue. Additional jobs will be held and submitted once the number of jobs in the queue drops below this value (optional);
- `mpiLaunch` If set to "`yes`" then the `mpirun` command will be used to launch a single copy of Galacticus (which may then spawn multiple OpenMP threads). If instead set to "`no`" then Galacticus is launch without the use of the `mpirun` command. Some systems will limit a code launched with `mpirun` to using just a single CPU (even if multiple OpenMP threads are spawned). In such cases, setting this option to "`no`" should permit multiple CPUs to be utilized.
- `mpiRun` The path to the `mpirun` executable (optional—if not present, `mpirun` must be in `PATH`);
- `environment` Any settings here are set in each PBS job in order to set appropriate environment variables on the machine where a job is executed;
- `analyze` If set to "`yes`" then analysis (if any) will be performed as part of the PBS job. Otherwise, analysis is performed by the submitting machine.
- `postSubmitSleepDuration` The time (in seconds) to wait after submitting each job. This prevents flooding the PBS queue manager with a large number of jobs in rapid succession.

`jobWaitSleepDuration` The time (in seconds) to sleep between successive checks of the PBS queue to see if any of the submitted jobs have finished.

`monolithicPBS` A single job will be submitted to a `PBS` batch queue system. This job will internally run multiple copies of Galacticus each with a different set of parameters. The following options are available and can be specified within a `monolithicPBS` XML block:

`nodes` The total number of nodes to use for the PBS job.

`threadsPerNode` The number of threads per node to use for the PBS job.

`ompThreads` The number of OpenMP threads to use for each model (optional). This is used to request an appropriate number of processors per node, and must be an factor of `threadsPerNode`;

`scratchPath` An optional path to which the model output will be written at run time. At the completion of each run, the data will be transferred to the usual output location. This is useful to avoid network I/O during run time;

`wallTime` A limit on the wall time allowed for each model (optional);

`memory` A limit on the memory allowed for each model (optional);

`queue` The name of the queue to submit the jobs to (optional);

`mpiRun` The path to the `mpirun` executable (optional—if not present, `mpirun` must be in `PATH`);

`environment` Any settings here are set in each PBS job in order to set appropriate environment variables on the machine where a job is executed;

`analyze` If set to "`yes`" then analysis (if any) will be performed as part of the PBS job. Otherwise, analysis is performed by the submitting machine.

`postSubmitSleepDuration` The time (in seconds) to wait after submitting each job. This prevents flooding the PBS queue manager with a large number of jobs in rapid succession.

`jobWaitSleepDuration` The time (in seconds) to sleep between successive checks of the PBS queue to see if any of the submitted jobs have finished.

`condor` Jobs will be submitted to a `Condor` cluster. The following options are available and can be specified within a `condor` XML block:

`galacticusDirectory` When a Galacticus job is submitted to a Condor cluster the Galacticus executable and the input parameter file are transferred to the machine where the job runs. Other files, such as data files, are not transferred. Therefore, they must be already present on any remote machine on which the job can run. This option specifies where a complete Galacticus installation can be found on the remote machine. If not present, it defaults to `/home/condor/Galacticus/v0.9.0`;

`universe` Specifies to which Condor universe jobs should be submitted. Allowed options are "vanilla" and "standard". If the standard universe is to be used then Galacticus must have been linked with `condor_compile`—the `Makefile` allows this if the relevant lines are uncommented;

`environment` Any settings here are passed to Condor's `environment` option in order to set appropriate environment variables on the machine where a job is executed;

`requirement` Any setting here is passed to Condor's `requirements` option to specify requirements for each job. Multiple `requirement` entries will be combined (using logical and).

`transferFile` Any files listed here will be transferred the Condor worker (and so will be accessible from the path in which Galacticus is running). The macro `{PWD}` will be automatically expanded to the present working directory. Multiple `transferFile` entries can be given.

`wholeFile` Setting this option to `true` will add `+RequiresWholeMachine = True` to the Condor submit file. If Condor has been configured to allow jobs to take over a whole machine[3], this will cause jobs to do so. This is useful if you want to run OpenMP Galacticus on a Condor cluster.

`postSubmitSleepDuration` The time (in seconds) to wait after submitting each job. This prevents flooding the Condor queue manager with a large number of jobs in rapid succession.

`jobWaitSleepDuration` The time (in seconds) to sleep between successive checks of the Condor queue to see if any of the submitted jobs have finished.

In addition to the `galacticus.hdf5` output file, each model directory will contain a file `newParameters.xml` which contains the parameters used to run the model and `galacticus.log` which contains any output from Galacticus during the run.

If present, the file `galacticusConfig.xml`, described in §2.1, is parsed for configuration options. If the `contact` element is present, the listed name and e-mail address will be used to determine who should receive error reports should a model crash. The error report will contain the host name of the computer running the model, the location of the model output and the log file (which may be incomplete if output is being buffered). Additionally, any core file produced will be stored in the model directory for later perusal, and the state files (see §2.3.2) for the run can also be found in the model directory.

2.3.4. Analysis of Models

The `Run_Galacticus.pl` script will automatically run `scripts/analysis/Galacticus_Compute_Fit.pl` on each model to generate plots and fitting data unless `doAnalysis=no` is set in the `runFile` (see §2.3.3). This script, which can also be running manually using

```
./scripts/analysis/Galacticus_Compute_Fit.pl <galacticusFile> <outputDirectory> [<analysisFile>]
```

where `galacticusFile` is the name of the Galacticus output file to analyze and `outputDirectory` is the directory into which plots and fitting data should be placed, reads the file `<analysisFile>` (or `data/Galacticus_Compute_Fit_Analyses.xml` if `<analysisFile>` is not specified) which has the following structure:

```
<analyses>
 <analysis>
   <script>scripts/plotting/Plot_HI_Mass_Function.pl</script>
   <weight>1.0</weight>
 </analysis>
 <analysis>
   <script>scripts/plotting/Plot_K_Luminosity_Function.pl</script>
   <weight>1.0</weight>
 </analysis>
 .
 .
 .
</analyses>
```

Each `analysis` element contains the name of a script to run to perform some analysis and a weight to be given to the results of this analysis when combining results to get a net goodness of fit. Each script listed will be run and is expected to have accept arguments of the form:

[3] As described here for example.

```
My_Analysis_Script.pl <galacticusFile> <outputDirectory> <showFit>
```

where the `showFit` argument can be 0 or 1 and, if set to 1, the script should output an XML chunk to standard output giving details of its fitting analysis. This chunk should have the form:

```
<galacticusFit>
  <name>Description of this analysis</name>
  <chiSquared>24.5</chiSquared>
  <degreesOfFreedom>19</degreesOfFreedom>
  <fileName>Output_File_Name.pdf</fileName>
</galacticusFit>
```

where `chiSquared` and `degreesOfFreedom` are the fitting results. All such data returned from fitting scripts will be collated by `Galacticus_Compute_Fit.pl`, augmented with the weight value and the net goodness of fit determined. All of this information is then output to `galacticusFits.xml` in the selected output directory.

Performing Other Analysis

If `<doAnalysis >=yes` and `<analysisFile>` is set to something other than an XML file it is assumed that this is an analysis script that should be run directly. The script will be executed with the output directory for the Galacticus model as the first and only argument.

2.3.5. Processing Individual Merger Trees In Parallel

By default, Galacticus utilizes the available parallel threads to process multiple merger trees simultaneously, with one tree processed by each thread. When the total number of trees to be processed is large, and there are not a small number of outlier trees with masses very much larger than the other trees, this approach generally results in good parallel efficiency.

However, in cases where a small number of trees are much more massive than any other (or are just slow to process for some other reason) it may be more efficient to have multiple parallel threads process each tree. To achieve this, set `[treeEvolveSingleForest]=true`. In this case, trees are processed sequentially, with multiple threads assigned to each tree. To do this, a tree is broken up into a set of time slices, or "sections". The number of sections between each successive output (or between the earliest node in the tree and the first output) is specified by the `[treeEvolveSingleForestSections]` parameter. Individual branches of the tree within each section are assigned to parallel threads. *Note that this results in valid evolution only if the evolution of disjoint tree branches are independent of each other.*

2.3.6. Running Models in "Embarrassingly Parallel" Mode

While Galacticus is parallelized via OpenMP it is also possible to split a given model across several "worker" CPUs on one or more computers. The trees to be processed will be shared between these workers and the results can be later recombined. To use this "poor man's" parallelization, add the following to a model parameter file:

```
  <treeEvolveWorkerCount  value="N" />
  <treeEvolveWorkerNumber value="i" />
```

where `N` is the total number of workers to be used and `i` is the number of this worker (ranging from 1 to `N`). You can generate these individual input parameter files from a single base parameter file using:

```
scripts/aux/Split_Models_For_Workers.pl <parameterFile> <workerCount>
```

where `<parameterFile>` is the name of the base parameter file and `<workerCount>` is the number of workers required. The script will create an input file for each worker (input files will have the same name as the base parameter file but with a "`_N`", where `N` is the worker number, inserted before the "`.xml`"). Output file name for each worker will be the same as specified in the base parameter file, but with a "`_N`", where `N` is the worker number, inserted before the "`.hdf5`".

Once all workers have finished, their outputs can (if required) be combined into a single output file using the `Merge_Models.pl` script as follows:

```
./scripts/aux/Merge_Models.pl <model1> <model2> .... <modelOutput>
```

where `model1` etc. are the names of the various output files and `modelOutput` is the file into which the combined results should be placed. The `Merge_Models.pl` script will combine all merger trees into the output file and will additionally cumulate any data in the `globalHistory` groups in these files. The UUIDs of the merged files (see §4.1.1) will be concatenated (with a ":" separator) and placed into the `UUIDs` attribute of the new file. Additionally, a new UUID will be generated and stored in the `UUID` attribute of the new file.

2.3.7. Limiting the Load Average

If `[treeEvolveLimitLoadAverage]=true` then Galacticus will attempt to keep the load average of the system under `[treeEvolveLoadAverageMaximum]` by waiting to run trees if the current load average exceeds this value. `[treeEvolveLoadAverageMaximum]` can be set to the numerical maximum load average desired or, alternatively, can be set to `processorCount` in which case the number of processor cores present on the system will be used for `[treeEvolveLoadAverageMaximum]`.

Thread Locking via Semaphores

An alternative is to use Linux's semaphoring system to share processors between multiple instances of Galacticus running on a single machine. To activiate this mode, set `[treeEvolveThreadLock]` to the total number of threads that should be active at any one time across all instances of Galacticus running on a machine. You can also set this parameter to `processorCount` to set a a value equal to the total number of processors on the machine. With this parameter set, each instance of Galacticus running on a machine will request a semaphore for each thread that it attempts to run, with the maximum number of semaphores set to the value of `[treeEvolveThreadLock]`. This means that, if one instance of Galacticus has claimed 6 semaphores when `[treeEvolveThreadLock]=8`, then a second instance of Galacticus will only run 2 threads. Once the first instance releases its semaphores, the second instance will claim them and begin running more threads.

2.4. Tasks

By default, Galacticus executes a single "task" when run—to evolve a set of merger tree forests and output the resulting halo and galaxy properties. Different tasks can be performed however, controlled by the `taskMethod` parameter.

2.4.1. `evolveForests`

This is the standard task performed by Galacticus. It takes a set of merger tree forests, evolves them, and outputs the resulting halo and galaxy properties.

2.4.2. multi

This task allows multiple sub-tasks to be run. For example:

```
<taskMethod value="multi">
  <taskMethod value="haloMassFunction"/>
  <taskMethod value="evolveForests"   />
</taskMethod>
```

would result in the `haloMassFunction` task being performed, followed by the `evolveForests` task.

2.4.3. haloMassFunction

The `haloMassFunction` task will tabulate the halo mass function and related quantities and output them to the main Galacticus output file. The tabulation is controlled by three sub- parameters:

`[haloMassMinimum]` The lowest mass halo (in units of $M_\odot$) at which to tabulate;

`[haloMassMaximum]` The highest mass halo (in units of $M_\odot$) at which to tabulate;

`[pointsPerDecade]` The number of points per decade of halo mass at which to tabulate.

T The halo mass function is computed at each output specified by the `[outputRedshifts]` parameter, and written to the corresponding `Outputs/OutputN` group with the following structure:

```
+-> Outputs
|   |
|   +-> OutputN
|       |
|       +-> massHaloCharacteristic         [attribute]
|       |
|       +-> criticalOverdensity            [attribute]
|       |
|       +-> outputExpansionFactor          [attribute]
|       |
|       +-> growthFactor                   [attribute]
|       |
|       +-> outputRedshift                 [attribute]
|       |
|       +-> outputTime                     [attribute]
|       |
|       +-> virialDensityContrast          [attribute]
|       |
|       +-> haloMass                       [dataset]
|       |
|       +-> haloSigma                      [dataset]
|       |
|       +-> haloAlpha                      [dataset]
|       |
|       +-> haloPeakHeightNu               [dataset]
|       |
|       +-> haloMassFunctionM              [dataset]
|       |
```

```
|       +-> haloMassFunctionLnM            [dataset]
|       |
|       +-> haloMassFunctionLnMBinAveraged [dataset]
|       |
|       +-> haloMassFunctionNuFNu          [dataset]
|       |
|       +-> haloMassFunctionCumulative     [dataset]
|       |
|       +-> haloMassFractionCumulative     [dataset]
|       |
|       +-> subhaloMassFunctionCumulative  [dataset]
|       |
|       +-> haloBias                       [dataset]
|       |
|       +-> haloVirialRadius               [dataset]
|       |
|       +-> haloVirialTemperature          [dataset]
|       |
|       +-> haloVirialVelocity             [dataset]
|       |
|       +-> haloScaleRadius                [dataset]
|       |
|       +-> haloVelocityMaximum            [dataset]
|
+-> cosmology
|   |
|   +-> densityCritical                    [attribute]
|
+-> powerSpectrum
    |
    +-> massHalfMode                       [attribute]
```

The `Outputs/OutputN` groups contain atrributes and datasets which give properties at the corresponding output time as follows:

`massHaloCharacteristic` The characteristic mass scale (in units of $\mathrm{M}_\odot$), M_*, at which $\sigma(M) = \delta_\mathrm{c}(z)$;

`criticalOverdensity` The critical overdensity for collapse of halos, δ_c;

`outputExpansionFactor` The expansion factor;

`growthFactor` The linear growth factor;

`outputRedshift` The redshift;

`outputTime` The cosmic time (in units of Gyr);

`virialDensityContrast` The virial density contrast of halos.

`haloMass` The mass of the halo, M_halo (in $\mathrm{M}_\odot$);

`haloSigma` The root-variance of the mass field smoothed in top-hat spheres, $\sigma(M)$;

`haloAlpha` The loagrithmic gradient of the root-variance of the mass field smoothed in top-hat spheres with mass, $\mathrm{d}\log\sigma(M)/\mathrm{d}\log M_{\rm halo}$;

`haloPeakHeightNu` The peak height of the halo, $\nu = \delta_{\rm c}/\sigma(M)$;

`haloMassFunctionM` The halo mass function per halo mass, $\mathrm{d}n/\mathrm{d}M_{\rm halo}$ (in units of $\mathrm{Mpc}^{-3}\mathrm{M}_\odot^{-1}$);

`haloMassFunctionLnM` The halo mass function per logarithmic halo mass, $\mathrm{d}n/\mathrm{d}\log M_{\rm halo}$ (in units of Mpc^{-3});

`haloMassFunctionLnMBinAveraged` The halo mass function per logarithmic halo mass averaged over the finite width of the bin (in units of Mpc^{-3});

`haloMassFunctionNuFNu` The halo mass function defined in terms of the peak-height parameter, $\nu F(\nu)$;

`haloMassFractionCumulative` The mass fraction in halos above the current halo mass;

`haloMassFunctionCumulative` The cumulative number of halos per unit volume above the current halo mass (in units of Mpc^{-3});

`subhaloMassFunctionCumulative` The cumulative number of sub-halos per unit volume above the current halo mass (in units of Mpc^{-3});

`haloBias` The large scale linear theory bias of the halo;

`haloVirialRadius` The virial radius (in units of Mpc) of the current halo mass;

`haloVirialTemperature` The virial temperature (in units of Kelvin) of the current halo mass;

`haloVirialVelocity` The virial velocity (in units of km/s) of the current halo mass;

`haloScaleRadius` The scale radius (in units of Mpc) of the current halo mass;

`haloVelocityMaximum` The peak of the rotation curve (in units of km/s) of the current halo mass;

Dimensionful datasets have an `unitsInSI` attribute that gives their units in the SI system.

Additionally, an attribute giving the critical density of the universe (in units of $\mathrm{M}_\odot\mathrm{Mpc}^{-3}$) is written to the `cosmology` group and, if such a scale is well-defined, an attribute given the mass corresponding to the scale at which the power spectrum is reduce by half relative to a CDM power spectrum in units of $\mathrm{M}_\odot$ is written as `massHalfMode` to the `powerSpectrum` group.

2.4.4. `excursionSets`

The `excursionSets` task will generate output which contains a variety of measures related to excursion sets in the Press-Schechter formalism. The results are output to a group specified by the `[outputGroup]` subparameter (which defaults to `excursionSets`). The output group contains the following structure:

```
+-> barrier                    [dataset]
|
+-> firstCrossingProbability [dataset]
|
+-> firstCrossingRate         [dataset]
|
+-> mass                       [dataset]
|
```

```
+-> massFunction              [dataset]
|
+-> powerSpectrum             [dataset]
|
+-> time                      [dataset]
|
+-> variance                  [dataset]
|
+-> wavenumber                [dataset]
```

These datasets contain the following information:

`mass` Halo mass [$\mathrm{M}_\odot$];

`time` Cosmic time [Gyr];

`wavenumber` Wavenumber corresponding to this halo mass [Mpc^{-1}];

`powerSpectrum` Power spectrum at this wavenumber [Mpc^3];

`variance` The variance, $S(M) \equiv \sigma^2(M)$, at this halo mass;

`barrier` The excursion set barrier, $B(S)$;

`firstCrossingProbability` The probability of first crossing this barrier between S and $S + \mathrm{d}S$;

`firstCrossingRate` The rate of first crossing of the barrier per unit time [Gyr^{-1}] for all pairs of halo mass;

`massFunction` The halo mass function [$\mathrm{M}_\odot^{-1}$ Mpc^{-3}].

2.4.5. `powerSpectra`

The `powerSpectra` task will output a variety of measures of the matter power spectrum tabulated as a function of wavenumber. The output data has the following structure:

```
+-> powerSpectrum
    |
    +-> alpha          [dataset]
    |
    +-> mass           [dataset]
    |
    +-> powerSpectrum  [dataset]
    |
    +-> sigma          [dataset]
    |
    +-> wavenumber     [dataset]
```

The `Parameters` group contains attributes giving the values of all used parameters (just as in a Galacticus output file). The `powerSpectrum` group contains datasets which give the power spectrum and related properties as follows:

`alpha` The logarithmic slope of $\sigma(M)$: $\alpha = \mathrm{d}\ln\sigma/\mathrm{d}\ln M$;

`mass` The mass scale, M, corresponding to the given wavenumber, k, defined such that $M = 4\pi\Omega_{\rm M}\rho_{\rm crit}/3k^3$ (in units of $\mathrm{M}_\odot$);

`powerSpectrum` The linear theory power spectrum at $z = 0$: $P(k)$ in units of Mpc^3;

`sigma` The dimensionless linear theory mass fluctuation at $z = 0$: $\sigma(M)$;

`wavenumber` The wavenumber in units of Mpc^{-1}.

Dimensionful datasets have an `unitsInSI` attribute that gives their units in the SI system.

3. Input Parameters

The following is an alphnumerically sorted list of all input parameters defined in Galacticus. Each parameter is listed by name, along with a description, default value (if one is specified in Galacticus), the file and program unit with which it is associated. Where relevant, references for parameters and the default values are given.

Name: `A`
Type: real 1
Default value: 2.881 Prada et al. [2011]
Description: The parameter A appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: `function:prada2011ConstructorParameters`
File: `dark_matter_profiles.structure.concentration.Prada2011.F90`
Used by:

Name: `A1`
Type: real 0..1
Default value: 3.44 [Obreschkow et al., 2009]
Description: The parameter, A_1, appearing in the model for the H_2/HI ratio in galaxies from Obreschkow et al. [2009].
Defined in: `function:obreschkow2009ConstructorParameters`
File: `galacticus.output.analyses.molecular_ratio.Obreschkow2009.F90`
Used by:

Name: `A2`
Type: real 0..1
Default value: 4.82 [Obreschkow et al., 2009]
Description: The parameter, A_2, appearing in the model for the H_2/HI ratio in galaxies from Obreschkow et al. [2009].
Defined in: `function:obreschkow2009ConstructorParameters`
File: `galacticus.output.analyses.molecular_ratio.Obreschkow2009.F90`
Used by:

Name: `B`
Type: real 1
Default value: 1.257 Prada et al. [2011]
Description: The parameter b appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: `function:prada2011ConstructorParameters`
File: `dark_matter_profiles.structure.concentration.Prada2011.F90`
Used by:

Name: `BCut`
Type: real 1
Default value: 1.47 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $B_{\rm cut}$ from the fitting functions of Behroozi et al. [2010].

Defined in: function:behroozi2010ConstructorParameters
File: halo_model.conditional_mass_function.Behroozi2010.F90
Used by:

Name: BSatellite
Type: real 1
Default value: 10.62 (Leauthaud et al. 2011; z_1 sample using their SIG_MOD1 method)
Description: The parameter $B_{\rm sat}$ from the fitting functions of Behroozi et al. [2010].
Defined in: function:behroozi2010ConstructorParameters
File: halo_model.conditional_mass_function.Behroozi2010.F90
Used by:

Name: C
Type: real 1
Default value: 1.022 Prada et al. [2011]
Description: The parameter c appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: C0
Type: real 1
Default value: 3.681 Prada et al. [2011]
Description: The parameter c_0 appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: C1
Type: real 1
Default value: 5.033 Prada et al. [2011]
Description: The parameter c_1 appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: D
Type: real 1
Default value: 0.060 Prada et al. [2011]
Description: The parameter d appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: F
Type: real 1
Default value: 0.01 Bullock et al. [2001]
Description: The parameter F appearing in the halo concentration algorithm of Bullock et al. [2001].
Defined in: function:bullock2001ConstructorParameters

File: dark_matter_profiles.structure.concentration.Bullock2001.F90
Used by:

Name: G0
Type: real 1
Default value: 0.57
Description: The parameter G_0 appearing in the modified merger rate expression of Parkinson et al. [2008].
Defined in: function:parkinsonColeHellyConstructorParameters
File: merger_trees.branching_probability.Parkinson_Cole_Helly.F90
Used by:

Name: HubbleConstant
Type: real 0..1
Default value: 67.36 (Planck Collaboration et al. 2018; TT,TE,EE+lowE+lensing)
Description: The present day value of the Hubble parameter in units of km/s/Mpc.
Defined in: function:simpleConstructorParameters
File: cosmology.parameters.simple.F90
Used by:

Name: K
Type: real 0..1
Default value: 11.3 [Obreschkow et al., 2009]
Description: The parameter, K (in units of m^4 kg^{-2}), appearing in the model for the H_2/HI ratio in galaxies from Obreschkow et al. [2009].
Defined in: function:obreschkow2009ConstructorParameters
File: galacticus.output.analyses.molecular_ratio.Obreschkow2009.F90
Used by:

Name: OmegaBaryon
Type: real 0..1
Default value: 0.04930 (Planck Collaboration et al. 2018; TT,TE,EE+lowE+lensing)
Description: The density of baryons in the Universe in units of the critical density.
Defined in: function:simpleConstructorParameters
File: cosmology.parameters.simple.F90
Used by:

Name: OmegaDarkEnergy
Type: real 0..1
Default value: 0.6847 (Planck Collaboration et al. 2018; TT,TE,EE+lowE+lensing)
Description: The density of dark energy in the Universe in units of the critical density.
Defined in: function:simpleConstructorParameters
File: cosmology.parameters.simple.F90
Used by:

Name: OmegaMatter
Type: real 0..1
Default value: 0.3153 (Planck Collaboration et al. 2018; TT,TE,EE+lowE+lensing)
Description: The density of matter in the Universe in units of the critical density.

Defined in: function:simpleConstructorParameters
File: cosmology.parameters.simple.F90
Used by:

Name: Rv
Type: real 1
Default value: 2.7
Description: The relative visibility, $R_{\rm V}$.
Defined in: function:prevotBouchetConstructorParameters
File: stellar_populations.spectra.dust_attenuation.Prevot-Bouchet.F90
Used by:

Name: X0
Type: real 1
Default value: 0.424 Prada et al. [2011]
Description: The parameter x_0 appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: X1
Type: real 1
Default value: 0.526 Prada et al. [2011]
Description: The parameter x_1 appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: a
Type: real 1
Default value: 1.36 [Trac et al., 2015]
Description: The parameter a for the Tinker et al. [2008] halo mass function.
Defined in: function:tinker2008GenericConstructorParameters
File: structure_formation.halo_mass_function.Tinker2008Generic.F90
Used by:

Name: a1
Type: real 1
Description: Parameter a_1 in the Dutton and Macciò [2014] halo concentration–mass relation.
Defined in: function:duttonMaccio2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90
Used by:

Name: a2
Type: real 1
Description: Parameter a_2 in the Dutton and Macciò [2014] halo concentration–mass relation.
Defined in: function:duttonMaccio2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90
Used by:

Name: a3
Type: real 1
Description: Parameter a_3 in the Dutton and Macciò [2014] halo concentration–mass relation.
Defined in: function:duttonMaccio2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90
Used by:

Name: a4
Type: real 1
Description: Parameter a_4 in the Dutton and Macciò [2014] halo concentration–mass relation.
Defined in: function:duttonMaccio2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90
Used by:

Name: absoluteMagnitudeThreshold
Type: real 0..1
Description: The parameter M_0 appearing in the stellar absolute magnitude threshold for the stellar absolute magnitude galactic filter class.
Defined in: function:stellarAbsoluteMagnitudesConstructorParameters
File: galactic.filters.stellar_absolute_magnitudes.F90
Used by:

Name: abundanceMaximum
Type: real 1
Default value: -1.0d0
Description: The abundance (in units of Mpc^{-3}) above which to truncate the halo mass function when sampling halo masses for tree construction. A negative value indicates no truncation.
Defined in: function:haloMassFunctionConstructorParameters
File: merger_trees.construct.build.masses.distribution.halo_mass_function.F90
Used by:

Name: abundanceMinimum
Type: real 1
Default value: -1.0d0
Description: The abundance (in units of Mpc^{-3}) below which to truncate the halo mass function when sampling halo masses for tree construction. A negative value indicates no truncation.
Defined in: function:haloMassFunctionConstructorParameters
File: merger_trees.construct.build.masses.distribution.halo_mass_function.F90
Used by:

Name: accelerationCoefficientGlobal
Type: real 1
Default value: 1.193
Description: Global accleration parameter.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: `accelerationCoefficientPersonal`
Type: real 1
Default value: 1.193
Description: Personal accleration parameter.
Defined in: `function:particleSwarmConstructorParameters`
File: `posterior_sampling.simulation.particle_swarm.F90`
Used by:

Name: `acceptanceAverageCount`
Type: integer 1
Default value: 10
Description: The number of steps over which to average the acceptance rate.
Defined in: `function:differentialEvolutionConstructorParameters`
File: `posterior_sampling.simulation.differential_evolution.F90`
Used by:

Name: `acceptanceRateMaximum`
Type: real 1
Description: The maximum acceptable acceptance rate.
Defined in: `function:adaptiveConstructorParameters`
File: `posterior_sampling.differential_proposal_size.adaptive.F90`
Used by:

Name: `acceptanceRateMinimum`
Type: real 1
Description: The minimum acceptable acceptance rate.
Defined in: `function:adaptiveConstructorParameters`
File: `posterior_sampling.differential_proposal_size.adaptive.F90`
Used by:

Name: `acceptedStateCount`
Type: integer 1
Default value: 100
Description: The number of states to use in acceptance rate statistics.
Defined in: `function:simpleConstructorParameters`
File: `posterior_sampling.state.simple.F90`
Used by:

Name: `accretionLimit`
Type: real 0..1
Default value: 0.1
Description: The largest fractional mass change due to subresolution accretion allowed in a timestep in merger trees built by the Cole et al. [2000] method.
Defined in: `function:cole2000ConstructorParameters`
File: `merger_trees.construct.builder.Cole2000.F90`
Used by:

Name: `accretionNegativeAllowed`
Type: boolean 1

Default value: .true.
Description: Specifies whether negative accretion (mass loss) is allowed in the simple halo accretion model.
Defined in: function:simpleConstructorParameters
File: accretion.halo.simple.F90
Used by:

Name: accretionNewGrowthOnly
Type: boolean 1
Default value: .false.
Description: Specifies whether accretion from the intergalactic medium (IGM) is allowed only when a halo is growing past its previous greatest mass.
Defined in: function:simpleConstructorParameters
File: accretion.halo.simple.F90
Used by:

Name: accretionRateThinDiskMaximum
Type: real 1
Default value: '0.3d0'
Description: The accretion rate (in Eddington units) above which a switched accretion disk becomes an ADAF.
Defined in: function:switchedConstructorParameters
File: accretion_disks.switched.F90
Used by:

Name: accretionRateThinDiskMinimum
Type: real 1
Default value: '0.01d0'
Description: The accretion rate (in Eddington units) below which a switched accretion disk becomes an ADAF.
Defined in: function:switchedConstructorParameters
File: accretion_disks.switched.F90
Used by:

Name: accretionRateTransitionWidth
Type: real 1
Default value: 0.1
Description: The width (in $\ln[\dot{M}/\dot{M}_{\rm Eddington}]$) over which transitions between accretion disk states occur.
Defined in: function:switchedConstructorParameters
File: accretion_disks.switched.F90
Used by:

Name: accuracyFirstOrder
Type: real 1
Default value: 0.1
Description: Limits the step in $\delta_{\rm crit}$ when constructing merger trees using the Parkinson et al. [2008] algorithm, so that it never exceeds `accuracyFirstOrder` $\sqrt{2[\sigma^2(M_2/2)-\sigma^2(M_2)]}$.
Defined in: function:parkinsonColeHellyConstructorParameters

File: merger_trees.branching_probability.Parkinson_Cole_Helly.F90
Used by:

Name: addHubbleFlow
Type: boolean 0..1
Default value: .false.
Description: If true, Hubble flow will be added to velocity offsets of halos (if applied).
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: adiabaticIndex
Type: real 1
Default value: adafAdiabaticIndexDefault(enumerationAdafFieldEnhancementEncode(char(fieldEnhancementOption),inclu
Description: Specifies the effective adiabatic index of gas in an ADAF.
Defined in: function:adafConstructorParameters
File: accretion_disks.ADAF.F90
Used by:

Name: ageEffective
Type: real 1
Default value: 13.8
Description: The effective age to use for computing SNeIa yield when using the instantaneous stellar evolution approximation.
Defined in: function:standardConstructorParameters
File: stellar_populations.standard.F90
Used by:

Name: ageFactor
Type: real 1
Default value: 0.0
Description: Interpolates (geometrically) between the age of the Universe and the halo dynamical time for the time available for cooling in the White and Frenk [1991] method.
Defined in: function:whiteFrenk1991ConstructorParameters
File: cooling.time_available.White-Frenk.F90
Used by:

Name: ageStatisticsStandardIsInactive
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the variables of the standard age statistics component are inactive (i.e. do not appear in any ODE being solved).
Defined in: subroutine:Node_Component_Age_Statistics_Standard_Initialize
File: objects.nodes.components.age_statistics.standard.F90
Used by:

Name: allTreesExistAtFinalTime
Type: boolean 1
Default value: .true.

Description: Specifies whether or not all merger trees are expected to exist at the final requested output time. If set to false, then trees which finish before a given output time will be ignored.
Defined in: function:standardConstructorParameters
File: merger_trees.evolver.standard.F90
Used by:

Name: allowBranchJumps
Type: boolean 1
Default value: .true.
Description: Specifies whether nodes are allowed to jump between branches.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: allowSubhaloPromotions
Type: boolean 1
Default value: .true.
Description: Specifies whether subhalos are permitted to be promoted to being isolated halos.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: alpha
Type: real 0..1
Default value: 0.0
Description: Parameter α appearing in model for simple systematic shift in the halo mass function.
Defined in: function:simpleSystematicConstructorParameters
File: structure_formation.halo_mass_function.simple_systematic.F90
Used by:

Name: alpha1
Type: real 0..1
Default value: -0.506d0 [Obreschkow et al., 2009]
Description: The parameter, α_1, appearing in the model for the H_2/HI ratio in galaxies from Obreschkow et al. [2009].
Defined in: function:obreschkow2009ConstructorParameters
File: galacticus.output.analyses.molecular_ratio.Obreschkow2009.F90
Used by:

Name: alpha2
Type: real 0..1
Default value: -1.054d0 [Obreschkow et al., 2009]
Description: The parameter, α_2, appearing in the model for the H_2/HI ratio in galaxies from Obreschkow et al. [2009].
Defined in: function:obreschkow2009ConstructorParameters
File: galacticus.output.analyses.molecular_ratio.Obreschkow2009.F90
Used by:

Name: alphaSatellite

Type: real 1
Default value: 1.0 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $\alpha_{\rm sat}$ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `alwaysIsolatedHalosOnly`
Type: integer 1
Default value: .true.
Description: Include only always-isolated halos when gathering tree root masses?
Defined in: `function:outputRootMassesConstructorParameters`
File: `merger_trees.operators.output_root_masses.F90`
Used by:

Name: `analyzeAllParticles`
Type: boolean 0..1
Default value: .true.
Description: If true, all particles are assumed to be self-bound at the beginning of the analysis. Unbound particles at previous times are allowed to become bound in the current snapshot. If false and the self-bound information from the previous snapshot is available, only the particles that are self-bound at the previous snapshot are assumed to be bound at the begnning of the anlysis.
Defined in: `function:selfBoundConstructorParameters`
File: `nBody.operator.self_bound.F90`
Used by:

Name: `angleRotation`
Type: float 1
Default value: 2.0d0*Pi*randomSequence%uniformSample() Uniformly random distribution between 0 and 2π.
Description: The angle through which the mock catalog should be rotated.
Defined in: `function:catalogProjectedCorrelationFunctionConstructorParameters`
File: `tasks.catalog_projected_correlation_function.F90`
Used by:

Name: `angularSize`
Type: real 0..1
Description: The angular size (i.e. side length) of the square field of view of the lightcone (in units of degrees).
Defined in: `function:squareConstructorParameters`
File: `geometry.lightcones.square.F90`
Used by:

Name: `apparentMagnitudeThreshold`
Type: real 0..1
Description: The parameter m_0 appearing in the stellar apparent magnitude threshold for the stellar apparent magnitude galactic filter class.
Defined in: `function:stellarApparentMagnitudesConstructorParameters`
File: `galactic.filters.stellar_apparent_magnitudes.F90`

Used by:

Name: `appendLogs`
Type: integer 1
Default value: .false.
Description: If true, do not overwrite existing log files, but instead append to them.
Defined in: `function:differentialEvolutionConstructorParameters`
File: `posterior_sampling.simulation.differential_evolution.F90`
Used by:

Name: `applyTo`
Type: real 0..1
Default value: var_str('nonRates')
Description: Specifies whether rescaling is to be applied to the barrier when used for rate calculation, for other calculations, or both.
Defined in: `function:remapScaleConstructorParameters`
File: `structure_formation.excursion_sets.barrier.remap.scale.F90`
Used by:

Name: `assumeMonotonicSurfaceDensity`
Type: boolean 1
Default value: .false.
Description: If true, assume that the surface density in disks is always monotonically decreasing.
Defined in: `function:krumholz2009ConstructorParameters`
File: `star_formation.rate_surface_density.disks.Krumholz2009.F90`
Used by:

Name: `attemptsMaximum`
Type: logical 0..
Default value: 10000
Description: The maximum allowed number of tree build attempts.
Defined in: `function:augmentConstructorParameters`
File: `merger_trees.operators.augment.F90`
Used by:

Name: `b`
Type: real 1
Default value: 2.54 [Trac et al., 2015]
Description: The parameter b for the Tinker et al. [2008] halo mass function.
Defined in: `function:tinker2008GenericConstructorParameters`
File: `structure_formation.halo_mass_function.Tinker2008Generic.F90`
Used by:

Name: `b1`
Type: real 1
Description: Parameter b_1 in the Dutton and Macciò [2014] halo concentration–mass relation.
Defined in: `function:duttonMaccio2014ConstructorParameters`
File: `dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90`
Used by:

Name: b2
Type: real 1
Description: Parameter b_2 in the Dutton and Macciò [2014] halo concentration–mass relation.
Defined in: function:duttonMaccio2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90
Used by:

Name: bRatioHigh
Type: real 1
Default value: [+2.878d0,+3.946d0,+2.982d0]
Description: Values of the B parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.05–0.5 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: bRatioIntermediate
Type: real 1
Default value: [+1.044d0,+1.535d0,+3.396d0]
Description: Values of the B parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.005–0.05 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: bRatioLow
Type: real 1
Default value: [+0.049d0,+0.548d0,+1.229d0]
Description: Values of the B parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.0001–0.005 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: badValue
Type: real 1
Default value: -0.5d0
Description: Use for bad value detection in "Sussing" merger trees. Values for scale radius and halo spin which exceed this threshold are assumed to be bad.
Defined in: function:sussingConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.F90
Used by:

Name: badValueTest
Type: real 1
Default value: var_str('lessThan')
Description: Use for bad value detection in "Sussing" merger trees. Values which exceed the threshold in ths specified direction are assumed to be bad.

Defined in: function:sussingConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.F90
Used by:

Name: band
Type: string 0..1
Description: The band (u, g, r, i, or z) for which the luminosity function should be computed.
Defined in: function:luminosityFunctionMonteroDorta2009SDSSConstructorParameters
File: galacticus.output.analyses.luminosity_function.Montero-Dorta2009.SDSS.F90
Used by:

Name: baseMassMaximum
Type: real 0..1
Default value: 0.0
Description: Base node mass above which trees should be ignored.
Defined in: function:selectWithinRangeConstructorParameters
File: merger_trees.operators.select_within_range.F90
Used by:

Name: baseMassMinimum
Type: real 0..1
Default value: 0.0
Description: Base node mass below which trees should be ignored.
Defined in: function:selectWithinRangeConstructorParameters
File: merger_trees.operators.select_within_range.F90
Used by:

Name: baseParametersFileName
Type: string 1
Description: The base set of parameters to use.
Defined in: function:galaxyPopulationConstructorParameters
File: models.likelihoods.galaxy_population.F90
Used by:

Name: beginAt
Type: integer 1
Default value: -1_kind_int8
Description: Specifies the index of the tree to begin at. (Use -1 to always begin with the first tree.)
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: beta
Type: real 0..1
Default value: 0.0
Description: Parameter β appearing in model for simple systematic shift in the halo mass function.
Defined in: function:simpleSystematicConstructorParameters
File: structure_formation.halo_mass_function.simple_systematic.F90
Used by:

Name: `beta0`
Type: real 0..1
Default value: 13.0 [Creasey et al., 2012]
Description: The parameter β_0 appearing in the Creasey et al. [2012] model for supernovae feedback.
Defined in: `function:creasey2012ConstructorParameters`
File: `star_formation.feedback.disks.Creasey2012.F90`
Used by:

Name: `betaCut`
Type: real 1
Default value: -0.13d0 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $\beta_{\rm cut}$ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `betaSatellite`
Type: real 1
Default value: 0.859 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $\beta_{\rm sat}$ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `binCenter`
Type: float 0..1
Description: The value of the property at the center of each bin.
Defined in: `function:volumeFunction1DConstructorParameters`
File: `galacticus.output.analyses.volume_function_1d.F90`
Used by:

Name: `binCountMinimum`
Type: real 1
Description: The minimum number of halos per bin required to permit bin to be included in likelihood evaluation.
Defined in: `function:haloMassFunctionConstructorParameters`
File: `models.likelihoods.halo_mass_function.F90`
Used by:

Name: `binWidthLogarithmic`
Type: real 1
Description: The logarithmic width of bins in the stellar mass function to be assumed when computing the optimal sampling density function for tree masses.
Defined in: `function:stellarMassFunctionConstructorParameters`
File: `merger_trees.construct.build.masses.distribution.stellar_mass_function.F90`
Used by:

Name: `binaryFormatOld`

Type: boolean 1
Default value: .false.
Description: Specifies whether the old binary format is to be used (for reading only).
Defined in: function:sussingASCIIConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.ASCII.F90
Used by:

Name: binnedProjectedCorrelationCovarianceTarget
Type: real 0..1
Description: The target function covariance for likelihood calculations.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: binnedProjectedCorrelationTarget
Type: real 0..1
Description: The target function for likelihood calculations.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: birthCloudLifetime
Type: real 1
Default value: 1.0×10^{-2}
Description: The duration which stars remain within their birth clouds.
Defined in: function:charlotFall2000ConstructorParameters
File: stellar_populations.spectra.dust_attenuation.CharlotFall2000.F90
Used by:

Name: blackHoleHeatingEfficiency
Type: double 1
Default value: 1.0×10^{-3}
Description: The efficiency with which accretion onto a black hole heats the hot halo.
Defined in: subroutine:Node_Component_Black_Hole_Simple_Initialize
File: objects.nodes.components.black_hole.simple.F90
Used by:

Name: blackHoleHeatsHotHalo
Type: boolean 1
Default value: .true.
Description: Specifies whether or not the black hole launched jets should heat the hot halo.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: blackHoleOutputAccretion
Type: boolean 1
Default value: .false.
Description: Determines whether or not accretion rates and jet powers will be output.

Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: blackHoleOutputData
Type: boolean 1
Default value: .false.
Description: Determines whether or not properties for all black holes (rather than just the central black hole) will be output.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: blackHoleOutputMergers
Type: boolean 1
Default value: .false.
Description: Determines whether or not properties of black hole mergers will be output.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: blackHoleRadioModeFeedbackEfficiency
Type: double 1
Default value: 1.0
Description: Efficiency with which radio-mode feedback is coupled to the hot halo.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: blackHoleSeedMass
Type: real 1
Default value: 100.0
Description: The mass of the seed black hole placed at the center of each newly formed galaxy.
Defined in: function:Node_Component_Black_Hole_Simple_Seed_Mass
File: objects.nodes.components.black_hole.simple.bound_functions.Inc
Used by:

Name: blackHoleToSpheroidStellarGrowthRatio
Type: double 1
Default value: 1.0×10^{-3}
Description: The ratio of the rates of black hole growth and spheroid stellar mass growth.
Defined in: subroutine:Node_Component_Black_Hole_Simple_Initialize
File: objects.nodes.components.black_hole.simple.F90
Used by:

Name: blackHoleWindEfficiency
Type: double 1
Default value: 2.4×10^{-3}
Description: The efficiency of the black hole-driven wind: $L_{\rm wind} = \epsilon_{\rm wind} \dot{M}_\bullet c^2$.

Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: blackHoleWindEfficiencyScalesWithRadiativeEfficiency
Type: double 1
Default value: .false.
Description: Specifies whether the black hole wind efficiency should scale with the radiative efficiency of the accretion disk.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: bondiHoyleAccretionEnhancementHotHalo
Type: double 1
Default value: 6.0
Description: The factor by which the Bondi-Hoyle accretion rate of hot halo gas onto black holes in enhanced.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: bondiHoyleAccretionEnhancementSpheroid
Type: double 1
Default value: 5.0
Description: The factor by which the Bondi-Hoyle accretion rate of spheroid gas onto black holes in enhanced.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: bondiHoyleAccretionHotModeOnly
Type: double 1
Default value: .true.
Description: Determines whether accretion from the hot halo should only occur if the halo is in the hot accretion mode.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: bondiHoyleAccretionTemperatureSpheroid
Type: double 1
Default value: 1.0×10^2
Description: The assumed temperature (in Kelvin) of gas in the spheroid when computing Bondi-Hoyle accretion rates onto black holes.
Defined in: subroutine:Node_Component_Black_Hole_Standard_Initialize
File: objects.nodes.components.black_hole.standard.F90
Used by:

Name: bootstrapSampleCount
Type: integer 0..1
Default value: 30_c_size_t
Description: The number of bootstrap resamples of the particles that should be used.
Defined in: function:velocityDispersionConstructorParameters
File: nBody.operator.velocity_dispersion.F90
Used by:

Name: bootstrapSampleRate
Type: float 0..1
Default value: 1.0
Description: The sampling rate for particles.
Defined in: function:selfBoundConstructorParameters
File: nBody.operator.self_bound.F90
Used by:

Name: branchIntervalStep
Type: boolean 0..1
Default value: .true.
Description: If `false` use the original Cole et al. [2000] method to determine whether branching occurs in a timestep. If `true` draw branching intervals from a negative exponential distribution.
Defined in: function:cole2000ConstructorParameters
File: merger_trees.construct.builder.Cole2000.F90
Used by:

Name: bufferCount
Type: integer 0..1
Description: The number of buffer bins to include below and above the range of actual bins.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: bufferIsolatedHalos
Type: boolean 0..1
Default value: .false.
Description: If true, intersection of a tree with the lightcone will be determined using the positions non-isolated (a.k.a. "satellite") halos, and of isolated halos (a.k.a "centrals") with a buffer region (with radius equal to the extent of the orphan satellite distribution—see §16.4.1) placed around each such halo, and any intersection of that region with the lightcone is sufficient to prevent pruning of the tree. If this parameter is `false` then (unbuffered) positions of all halos are used for determining intersection with the lightcone—this requires complete (i.e. throughout the extent of their existance) knowledge of non-isolated halos prior to application of this operator.
Defined in: function:pruneLightconeConstructorParameters
File: merger_trees.operators.prune_lightcone.F90
Used by:

Name: burnCount
Type: integer 1
Default value: 0

Description: The number of steps to burn before computing convergence.
Defined in: function:gelmanRubinConstructorParameters
File: posterior_sampling.convergence.Gelman-Rubin.F90
Used by:

Name: burstCount
Type: real 1
Description: The number of bursts events to include in the star formation history.
Defined in: function:sedFitConstructorParameters
File: models.likelihoods.SED_fit.F90
Used by:

Name: c
Type: real 1
Default value: 1.14 [Trac et al., 2015]
Description: The parameter c for the Tinker et al. [2008] halo mass function.
Defined in: function:tinker2008GenericConstructorParameters
File: structure_formation.halo_mass_function.Tinker2008Generic.F90
Used by:

Name: cdmAssumptions
Type: real 1
Default value: .false.
Description: If true, assume that $\alpha(= -\mathrm{d}\log\sigma/\mathrm{d}\log M) > 0$ and $\mathrm{d}\alpha/\mathrm{d}M > 0$ (as is true in the case of CDM) when constructing merger trees using the Parkinson et al. [2008].
Defined in: function:parkinsonColeHellyConstructorParameters
File: merger_trees.branching_probability.Parkinson_Cole_Helly.F90
Used by:

Name: chainBaseName
Type: string 1
Description: The base name of the MCMC chain files to read.
Defined in: function:posteriorAsPriorConstructorParameters
File: models.likelihoods.posterior_as_prior.F90
Used by:

Name: chemicalsToTrack
Type: string 1..*
Description: The names of the chemicals to be tracked.
Defined in: subroutine:Chemical_Abundances_Initialize
File: objects.chemical_abundances.F90
Used by:

Name: chunkSize
Type: integer 0..1
Default value: -1
Description: HDF5 dataset chunk size.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90

Used by:

Name: `clumpingFactorMolecularComplex`
Type: real 1
Default value: 5.0
Description: The density enhancement (relative to mean disk density) for molecular complexes in the "Krumholz-McKee-Tumlinson" star formation timescale calculation.
Defined in: `function:krumholz2009ConstructorParameters`
File: `star_formation.rate_surface_density.disks.Krumholz2009.F90`
Used by:

Name: `coefficient`
Type: float 0..1
Description: The coefficients in the polynomial systematic offset property operator class.
Defined in: `function:systmtcPolynomialConstructorParameters`
File: `galacticus.output.analyses.property_operator.systematic.polynomial.F90`
Used by:

Name: `coefficientConstant`
Type: real 0..1
Default value: 1.67
Description: The constant coefficient in the quadratic excursion set barrier.
Defined in: `function:quadraticConstructorParameters`
File: `structure_formation.excursion_sets.barrier.quadratic.F90`
Used by:

Name: `coefficientLinear`
Type: real 0..1
Default value: 0.0
Description: The linear coefficient in the quadratic excursion set barrier.
Defined in: `function:quadraticConstructorParameters`
File: `structure_formation.excursion_sets.barrier.quadratic.F90`
Used by:

Name: `coefficientQuadratic`
Type: real 0..1
Default value: 0.0
Description: The quadratic coefficient in the quadratic excursion set barrier.
Defined in: `function:quadraticConstructorParameters`
File: `structure_formation.excursion_sets.barrier.quadratic.F90`
Used by:

Name: `column`
Type: integer 1
Description: The column from which to read the particle property.
Defined in: `function:mergerTreeFileBuilderConstructorParameters`
File: `tasks.merger_tree_file_builder.F90`
Used by:

Name: `columnHeaders`
Type: string 1
Default value: .false.
Description: If true, the file is assumed to contain a single line of column headers, which will be skipped.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: `columnSeparator`
Type: string 1
Default value: var_str(',')
Description: The separator for columns.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: `comment`
Type: string 0..1
Description: A descriptive comment for the analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: `computeCovariances`
Type: boolean 1
Default value: .false.
Description: Compute covariances for accumulated statistics?
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: `computeScatter`
Type: logical 0..1
Default value: .false.
Description: If true, the scatter in log10(stellar mass) is computed. Otherwise, the mean is computed.
Defined in: function:stellarVsHaloMassRelationLeauthaud2012ConstructorParameters
File: galacticus.output.analyses.stellar_vs_halo_mass_relation.COSMOS_Leauthaud2012.F90
Used by:

Name: `computeVelocityDispersion`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the velocity dispersion of dark matter and stars should be computed using Jeans equation in black hole binary hardening calculations. If `false`, then the velocity dispersions are assumed to equal the characteristic velocity of dark matter and spheroid.
Defined in: function:standardConstructorParameters
File: black_holes.binaries.separation_growth_rate.standard.F90
Used by:

Name: `concentration`
Type: real 1
Default value: 1.0
Description: The concentration of the NFW profile.
Defined in: `function:nfwConstructorParameters`
File: `mass_distributions.spherical.NFW.F90`
Used by:

Name: `constant`
Type: real 1
Description: The constant error contribution to the stellar mass function to be assumed when computing the optimal sampling density function for tree masses.
Defined in: `function:stellarMassFunctionConstructorParameters`
File: `merger_trees.construct.build.masses.distribution.stellar_mass_function.F90`
Used by:

Name: `content`
Type: string 1
Description: The value of the metadata.
Defined in: `function:mergerTreeFileBuilderConstructorParameters`
File: `tasks.merger_tree_file_builder.F90`
Used by:

Name: `conversionFactor`
Type: float 1
Description: An additional conversion factor to apply to the property to get it into the correct units.
Defined in: `function:mergerTreeFileBuilderConstructorParameters`
File: `tasks.merger_tree_file_builder.F90`
Used by:

Name: `convertToBinary`
Type: boolean 1
Default value: .true.
Description: Specifies whether halo and tree files in the "Sussing" format should be converted to binary the first time they are read and stored to file. This allows rapid re-reading in future.
Defined in: `function:sussingASCIIConstructorParameters`
File: `merger_trees.construct.read.importer.SussingMergerTrees.ASCII.F90`
Used by:

Name: `coreRadius`
Type: real 1
Description: The core radius of a β-model mass distribution.
Defined in: `function:betaProfileConstructorParameters`
File: `mass_distributions.spherical.beta_profile.F90`
Used by:

Name: `coreRadiusOverScaleRadius`
Type: real 1
Default value: 0.1

Description: The core radius in the hot halo density profile in units of the dark matter profile scale radius.
Defined in: function:growingConstructorParameters
File: hot_halo.mass_distribution.cored.core_radius.growing.F90
Used by:

Name: coreRadiusOverVirialRadius
Type: real 1
Default value: 0.3
Description: The core radius in the hot halo density profile in units of the virial radius.
Defined in: function:virialFractionConstructorParameters
File: hot_halo.mass_distribution.cored.core_radius.virial_radius_fraction.F90
Used by:

Name: coreRadiusOverVirialRadiusMaximum
Type: real 1
Default value: 10.0
Description: The maximum core radius in the "growing" hot halo density profile in units of the virial radius.
Defined in: function:growingConstructorParameters
File: hot_halo.mass_distribution.cored.core_radius.growing.F90
Used by:

Name: correctForConcentrationDefinition
Type: string 1
Default value: .false.
Description: If true, then when computing dark matter profile scale radii using concentrations, any difference between the current definition of halo scales (i.e. typically virial density contrast definitions) and density profiles and those assumed in measuring the concentrations will be taken into account. If false, the concentration is applied blindly.
Defined in: function:concentrationConstructorParameters
File: dark_matter_profiles.structure.scale.concentration.F90
Used by:

Name: correlationMassExponent
Type: real 0..1
Default value: 0.0
Description: Variable α in the model for the correlation between halo mass errors: $C_{12} = C_0[M_2/M_1]^\alpha[(1+z_2)/(1+z_1)]^\beta$.
Defined in: function:nbodyHaloMassErrorTrenti2010Parameters
File: statistics.Nbody.halos.mass_errors.Trenti2010.F90
Used by:

Name: correlationNormalization
Type: real 0..1
Default value: 0.0
Description: Variable C_0 in the model for the correlation between halo mass errors: $C_{12} = C_0[M_2/M_1]^\alpha[(1+z_2)/(1+z_1)]^\beta$.
Defined in: function:nbodyHaloMassErrorTrenti2010Parameters

File: statistics.Nbody.halos.mass_errors.Trenti2010.F90
Used by:

Name: correlationRedshiftExponent
Type: real 0..1
Default value: 0.0
Description: Variable β in the model for the correlation between halo mass errors: $C_{12} = C_0[M_2/M_1]^{\alpha}[(1+z_2)/(1+z_1)]^{\beta}$.
Defined in: function:nbodyHaloMassErrorTrenti2010Parameters
File: statistics.Nbody.halos.mass_errors.Trenti2010.F90
Used by:

Name: countFailures
Type: real 1
Description: The number of failures.
Defined in: function:negativeBinomialConstructorParameters
File: statistics.distributions.discrete.negative_binomial.F90
Used by:

Name: countHistoryTimes
Type: integer 1
Default value: 10
Description: The number of times at which a galaxy's stellar properties history is stored.
Defined in: function:noninstantaneousConstructorParameters
File: stellar_populations.properties.noninstantaneous.F90
Used by:

Name: countMass
Type: string 1
Default value: 21
Description: The number of bins for which to compute the conditional mass function.
Defined in: function:conditionalMassFunctionConstructorParameters
File: tasks.conditional_mass_function.F90
Used by:

Name: countMassBins
Type: boolean 1
Default value: 10
Description: The number of bins in the mass function for covariance calculations.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: countMetallicities
Type: integer 1
Default value: 10
Description: The number of bins in metallicity to use when tabulating star formation histories.
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90

Used by:

Name: `countSeparations`
Type: string 1
Description: The number of separations at which to compute the projected correlation function.
Defined in: `function:haloModelProjectedCorrelationFunctionConstructorParameters`
File: `tasks.halo_model.projected_correlation_function.F90`
Used by:

Name: `countSteps`
Type: integer 1
Default value: 100
Description: The number of steps (spaced logarithmically in cosmic time) at which to tabulate the evolution of main branch progenitor galaxies.
Defined in: `function:recordEvolutionConstructorParameters`
File: `merger_trees.evolve.timesteps.record_evolution.F90`
Used by:

Name: `countTrials`
Type: integer 1
Description: The number of trials.
Defined in: `function:binomialConstructorParameters`
File: `statistics.distributions.discrete.binomial.F90`
Used by:

Name: `covariance`
Type: real 1
Description: The covariance matrix for the of the multivariate normal distribution.
Defined in: `function:multivariateNormalStochasticConstructorParameters`
File: `models.likelihoods.multivariate_normal.stochastic.F90`
Used by:

Name: `covarianceBinomialBinsPerDecade`
Type: real 0..1
Default value: 10
Description: The number of bins per decade of halo mass to use when constructing volume function covariance matrices for main branch galaxies.
Defined in: `function:volumeFunction1DConstructorParameters`
File: `galacticus.output.analyses.volume_function_1d.F90`
Used by:

Name: `covarianceBinomialMassHaloMaximum`
Type: real 0..1
Default value: 1.0×10^{16}
Description: The maximum halo mass to consider when constructing volume function covariance matrices for main branch galaxies.
Defined in: `function:volumeFunction1DConstructorParameters`
File: `galacticus.output.analyses.volume_function_1d.F90`
Used by:

Name: `covarianceBinomialMassHaloMinimum`
Type: real 0..1
Default value: 1.0×10^8
Description: The minimum halo mass to consider when constructing volume function covariance matrices for main branch galaxies.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: `covarianceModel`
Type: float 0..1
Description: The model to use for computing covariances.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: `cpuLimit`
Type: integer 1
Default value: 0_c_long
Description: The CPU time limit for the run, in seconds.
Defined in: subroutine:System_Limits_Set
File: system.limits.F90
Used by:

Name: `criticalOverdensity`
Type: real 0..1
Default value: (3.0d0/20.0d0)*(12.0d0*Pi)**(2.0d0/3.0d0)
Description: The value to use for the critical overdensity for collapse of dark matter halos when using a fixed value.
Defined in: function:fixedConstructorParameters
File: structure_formation.critical_overdensity.fixed.F90
Used by:

Name: `darkEnergyEquationOfStateW0`
Type: real 1
Default value: -1.0d0
Description: The equation of state parameter for dark energy, w_0, defined such that $P = \rho^w$ with $w(a) = w_0 + w_1 a(1-a)$.
Defined in: function:matterDarkEnergyConstructorParameters
File: cosmology.functions.matter_dark_energy.F90
Used by:

Name: `darkEnergyEquationOfStateW1`
Type: real 1
Default value: 0.0
Description: The equation of state parameter for dark energy, w_1, defined such that $P = \rho^w$ with $w(a) = w_0 + w_1 a(1-a)$.
Defined in: function:matterDarkEnergyConstructorParameters

File: cosmology.functions.matter_dark_energy.F90
Used by:

Name: darkMatterOnly
Type: boolean 1
Default value: .false.
Description: Specifies whether or not density contrast data should be computed using the dark matter component alone.
Defined in: function:densityContrastsConstructorParameters
File: nodes.property_extractor.density_contrasts.F90
Used by:

Name: darkMatterProfileMaximumConcentration
Type: double 1
Default value: 100.0
Description: The maximum concentration allowed for dark matter profiles.
Defined in: subroutine:Node_Component_Dark_Matter_Profile_Scale_Initialize
File: objects.nodes.components.dark_matter_profile.scale.F90
Used by:

Name: darkMatterProfileMinimumConcentration
Type: double 1
Default value: 4.0
Description: The minimum concentration allowed for dark matter profiles.
Defined in: subroutine:Node_Component_Dark_Matter_Profile_Scale_Initialize
File: objects.nodes.components.dark_matter_profile.scale.F90
Used by:

Name: definition
Type: string 1
Description: The definition of the parameter.
Defined in: function:derivedConstructorParameters
File: models.parameters.derived.F90
Used by:

Name: degreesOfFreedom
Type: real 1
Description: The degrees of freedom of the Student-t distribution function.
Defined in: function:studentTConstructorParameters
File: statistics.distributions.Student-t.F90
Used by:

Name: degreesOfFreedomEffective
Type: real 1
Default value: 1.5
Description: The effective number of degrees of freedom for the thermal warm dark matter particle.
Defined in: function:wdmThermalConstructorParameters
File: dark_matter.particle.warm_dark_matter.thermal.F90
Used by:

Name: `delta`
Type: real 1
Default value: 0.5666 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter δ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `delta1`
Type: real 1
Default value: 2.40 Henriques et al. [2013]
Description: The exponent of the $(1 + z)$ term, δ_1.
Defined in: `function:henriques2013ConstructorParameters`
File: `hot_halo.outflow_reincorporation.Henriques2013.F90`
Used by:

Name: `delta2`
Type: real 1
Default value: 3.07 Henriques et al. [2013]
Description: The exponent of the $V_{\rm vir}$ term, δ_2.
Defined in: `function:henriques2013ConstructorParameters`
File: `hot_halo.outflow_reincorporation.Henriques2013.F90`
Used by:

Name: `deltaStepMaximum`
Type: real 1
Default value: 0.1
Description: Limits the step in $\delta_{\rm crit}$ when constructing merger trees using the generalized Press-Schechter branching algorithm.
Defined in: `function:generalizedPressSchechterConstructorParameters`
File: `merger_trees.branching_probability.generalized_Press_Schechter.F90`
Used by:

Name: `densityContrastValue`
Type: float 1
Default value: 200.0
Description: The virial density contrast to use in the fixed value model.
Defined in: `function:fixedConstructorParameters`
File: `structure_formation.virial_density_contrast.fixed.F90`
Used by:

Name: `densityContrasts`
Type: real 1..*
Description: A list of density contrasts at which to output data.
Defined in: `function:densityContrastsConstructorParameters`
File: `nodes.property_extractor.density_contrasts.F90`
Used by:

Name: densityNormalization
Type: real 1
Description: The density normalization of a β-model mass distribution.
Defined in: function:betaProfileConstructorParameters
File: mass_distributions.spherical.beta_profile.F90
Used by:

Name: densityParticleMean
Type: real 0..1
Description: The mean density of particles in the simulation.
Defined in: function:environmentalOverdensityConstructorParameters
File: nBody.operator.environmental_overdensity.F90
Used by:

Name: densityRatio
Type: real 1
Default value: 4.688 Value appropriate for an Navarro-Frenk-White (dark matter halo profile) (NFW) profile with concentration $c = 6.88$ which is the concentration found by Prada et al. [2011] for halos with $\sigma = 1.686$ which is the approximate critical overdensity for collapse.
Description: The ratio of mean virial density to density at the virial radius to assume when setting virial density contrasts in the friends-of-friends model.
Defined in: function:friendsOfFriendsConstructorParameters
File: structure_formation.virial_density_contrast.friends-of-friends.F90
Used by:

Name: densityType
Type: string 1
Default value: var_str('critical')
Description: The reference density to use in the fixed value virial density contrast model. Either of critical and mean are allowed.
Defined in: function:fixedConstructorParameters
File: structure_formation.virial_density_contrast.fixed.F90
Used by:

Name: depthLineOfSight
Type: string 1
Description: The maximum line of sight depth to which to integrate when computing the projected correlation function.
Defined in: function:haloModelProjectedCorrelationFunctionConstructorParameters
File: tasks.halo_model.projected_correlation_function.F90
Used by:

Name: depthOpticalCloudsCoefficient
Type: string 0..1
Default value: 1.0
Description: Multiplicative coefficient for optical depth in birth clouds.
Defined in: function:lmnstyStllrChrltFll2000ConstructorParameters
File: nodes.property_extractor.luminosity_stellar.dust.CharlotFall2000.F90
Used by:

Name: `depthOpticalISMCoefficient`
Type: string 0..1
Default value: 1.0
Description: Multiplicative coefficient for optical depth in the ISM.
Defined in: `function:lmnstyStllrChrltFll2000ConstructorParameters`
File: `nodes.property_extractor.luminosity_stellar.dust.CharlotFall2000.F90`
Used by:

Name: `description`
Type: boolean 1
Description: A description of this property.
Defined in: `function:ratioConstructorParameters`
File: `nodes.property_extractor.ratio.F90`
Used by:

Name: `destinationGasMinorMerger`
Type: string 1
Default value: var_str('spheroid')
Description: The component to which satellite galaxy gas moves to as a result of a minor merger.
Defined in: `function:simpleConstructorParameters`
File: `satellites.merging.mass_movements.simple.F90`
Used by:

Name: `dimensionless`
Type: boolean 1
Description: If true then the β-model mass distribution is considered to be in dimensionless units.
Defined in: `function:betaProfileConstructorParameters`
File: `mass_distributions.spherical.beta_profile.F90`
Used by:

Name: `discriminator`
Type: string 1
Default value: var_str('boundMass')
Description: Specifies whether bound mass or position history will be used to determine satellite orphan status.
Defined in: `function:satelliteStatusConstructorParameters`
File: `nodes.property_extractor.satellite_status.F90`
Used by:

Name: `diskLuminositiesStellarInactive`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not disk stellar luminosities are inactive properties (i.e. do not appear in any ODE being solved).
Defined in: `subroutine:Node_Component_Disk_Standard_Initialize`
File: `objects.nodes.components.disk.standard.F90`
Used by:

Name: diskMassToleranceAbsolute
Type: double 1
Default value: 1.0×10^{-6}
Description: The mass tolerance used to judge whether the disk is physically plausible.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Size_Initialize
File: objects.nodes.components.disk.very_simple.size.F90
Used by:

Name: diskNegativeAngularMomentumAllowed
Type: double 1
Default value: .true.
Description: Specifies whether or not negative angular momentum is allowed for the disk.
Defined in: subroutine:Node_Component_Disk_Standard_Initialize
File: objects.nodes.components.disk.standard.F90
Used by:

Name: diskOutflowTimescaleMinimum
Type: double 1
Default value: 1.0×10^{-3}
Description: The minimum timescale (in units of the halo dynamical time) on which outflows may deplete gas in the disk.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskOutputStarFormationRate
Type: string 1
Default value: .false.
Description: Specifies whether the
normalfont
ttfamily starFormationRate method of the
normalfont
ttfamily standard implemention of the
normalfont
ttfamily component class should be output.
Defined in: subroutine:nodeClassHierarchyInitialize
File: objects.nodes.components.Inc
Used by:

Name: diskRadiusSolverCole2000Method
Type: boolean 1
Default value: .false.
Description: HASH(0x3169f28)
Defined in: subroutine:Node_Component_Disk_Standard_Initialize
File: objects.nodes.components.disk.standard.F90
Used by:

Name: diskStarFormationInSatellites
Type: boolean 1

Default value: .true.
Description: Specifies whether or not star formation occurs in disks in satellites.
Defined in: subroutine:Node_Component_Disk_Standard_Initialize
File: objects.nodes.components.disk.standard.F90
Used by:

Name: diskStarFormationTimescaleMinimum
Type: double 1
Default value: 1.0×10^{-3}
Description: The minimum timescale (in units of the halo dynamical time) on which star formation may occur in the disk.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskStructureSolverRadius
Type: double 1
Default value: 1.0
Description: The radius (in units of the standard scale length) to use in solving for the size of the disk.
Defined in: subroutine:Node_Component_Disk_Standard_Initialize
File: objects.nodes.components.disk.standard.F90
Used by:

Name: diskVerySimpleAnalyticSolverPruneMassGas
Type: double 1
Default value: 0.0
Description: Gas mass below which the analytic solver will prune a galaxy.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleAnalyticSolverPruneMassStars
Type: double 1
Default value: 0.0
Description: Stellar mass below which the analytic solver will prune a galaxy.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleMassScaleAbsolute
Type: double 1
Default value: 100.0
Description: The absolute mass scale below which calculations in the very simple disk component are allowed to become inaccurate.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleSurfaceDensityThreshold

Type: double 1
Default value: 0.0
Description: The threshold gas surface denisty above this star formation occurs [$M_\odot$/Mpc^2].
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleSurfaceDensityVelocityExponent
Type: double 1
Default value: 0.0
Description: The exponent of velocity in the threshold gas surface denisty above this star formation occurs.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleTrackAbundances
Type: boolean 0..1
Default value: .false.
Description: Specifies whether or not to track abundances in the very simple disk component.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleTrackLuminosities
Type: boolean 0..1
Default value: .false.
Description: Specifies whether or not to track stellar luminosities in the very simple disk component.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: diskVerySimpleUseAnalyticSolver
Type: boolean 1
Default value: .false.
Description: If true, employ an analytic ODE solver when evolving satellites.
Defined in: subroutine:Node_Component_Disk_Very_Simple_Initialize
File: objects.nodes.components.disk.very_simple.F90
Used by:

Name: distanceMaximumSurvey
Type: float 0..1
Default value: 300.0×10^{-3}
Description: The maximum distance for the sample of classical Local Group galaxies.
Defined in: function:localGroupClassicalConstructorParameters
File: geometry.surveys.Local_Group_classical.F90
Used by:

Name: distributionComment

Type: string 0..1
Description: A descriptive comment for the distribution.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: distributionLabel
Type: string 0..1
Description: A label for the distribution.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: distributionNumber
Type: real 0..1
Description: The number (1-34) of the distribution to compute.
Defined in: function:galaxySizesSDSSConstructorParameters
File: galacticus.output.analyses.galaxy_sizes_SDSS.F90
Used by:

Name: distributionType
Type: string 1
Description: The name of the spin distribution to use.
Defined in: function:spinDistributionConstructorParameters
File: models.likelihoods.spin_distribution.F90
Used by:

Name: distributionUnits
Type: string 0..1
Description: A human-readable description of the units for the distribution.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: distributionUnitsInSI
Type: string 0..1
Description: A units for the distribution in the SI system.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: dummyEmulator
Type: boolean 1
Default value: .false.
Description: If true, then the emulator is constructed, and performance measured, but likelihoods are always simulated directly.
Defined in: function:gaussianRegressionConstructorParameters
File: models.likelihoods.gaussian_regression.F90
Used by:

Name: `dummyHostId`
Type: real 1
Description: If present, specifies the dummy host ID for self-hosting halos. Otherwise, self-hosting halos have `hostIndex == nodeIndex`.
Defined in: `function:mergerTreeFileBuilderConstructorParameters`
File: `tasks.merger_tree_file_builder.F90`
Used by:

Name: `dumpEmulatorFileRoot`
Type: string 1
Default value: var_str('')
Description: The name of a file to which emulator internal state will be dumped. (If empty, no dump occurs.)
Defined in: `function:gaussianRegressionConstructorParameters`
File: `models.likelihoods.gaussian_regression.F90`
Used by:

Name: `dumpTreeStructure`
Type: boolean 1
Default value: .false.
Description: Specifies whether merger tree structure should be dumped to a DOT file.
Defined in: `function:standardConstructorParameters`
File: `merger_trees.evolver.standard.F90`
Used by:

Name: `dumpTrees`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to dump merger trees as they are regridded.
Defined in: `function:regridTimesConstructorParameters`
File: `merger_trees.operators.regrid_times.F90`
Used by:

Name: `dustType`
Type: string 1
Description: The type of dust model to apply to the SED.
Defined in: `function:sedFitConstructorParameters`
File: `models.likelihoods.SED_fit.F90`
Used by:

Name: `dynamicalRateFraction`
Type: real 1
Default value: 2.0
Description: The fraction of the inverse dynamical time to use as the rate for infall of the cold mode component.
Defined in: `function:dynamicalTimeConstructorParameters`
File: `cooling.cold_mode.infall_rate.dynamical_time.F90`
Used by:

Name: `dynamicsStatisticsBarsFrequency`
Type: double 1
Default value: 0.1
Description: The frequency (in fractions of the host halo dynamical time) at which to record the bar dynamical status of satellite galaxies.
Defined in: `subroutine:Node_Component_Dynamics_Statistics_Bars_Initialize`
File: `objects.nodes.components.dynamics_statistics.bars.F90`
Used by:

Name: `edgeLengthsToTimes`
Type: boolean 1
Default value: .true.
Description: Specifies whether or not the lengths of edges in the graph should be scaled to time differences between nodes.
Defined in: `function:dumpToGraphVizConstructorParameters`
File: `merger_trees.operators.dump_to_GraphViz.F90`
Used by:

Name: `efficiency`
Type: float 1
Description: The fractional efficiency of two-body relaxation heating.
Defined in: `function:twoBodyRelaxationConstructorParameters`
File: `dark_matter_profiles.heating.two_body_relaxation.F90`
Used by:

Name: `efficiencyJet`
Type: real 0..1
Default value: 0.1
Description: The jet efficiency of the Eddington-limited accretion disk.
Defined in: `function:eddingtonLimitedConstructorParameters`
File: `accretion_disks.Eddington_limited.F90`
Used by:

Name: `efficiencyJetMaximum`
Type: real 1
Default value: 2.0
Description: The maximum efficiency allowed for ADAF-driven jets (in units of the accretion power).
Defined in: `function:adafConstructorParameters`
File: `accretion_disks.ADAF.F90`
Used by:

Name: `efficiencyRadiation`
Type: real 0..1
Default value: 0.1
Description: The radiative efficiency of the Eddington-limited accretion disk.
Defined in: `function:eddingtonLimitedConstructorParameters`
File: `accretion_disks.Eddington_limited.F90`
Used by:

Name: `efficiencyRadiationType`
Type: string 0..1
Default value: var_str('thinDisk')
Description: Specifies the specific energy of material at the inner edge of an ADAF. `pureADAF` makes the specific energy equal to 1 (i.e. all energy is advected with the flow); `ISCO` makes the specific energy equal to that for the innermost stable circular orbit.
Defined in: `function:adafConstructorParameters`
File: `accretion_disks.ADAF.F90`
Used by:

Name: `efficiencyRadiative`
Type: real 1
Default value: 2.75 [Covington et al., 2008]
Description: The coefficient, $C_{\rm rad}$ energy used in the Covington et al. [2008] merger remnant size algorithm.
Defined in: `function:covington2008ConstructorParameters`
File: `satellites.merging.remnant_sizes.Covington2008.F90`
Used by:

Name: `electronScatteringOpticalDepth`
Type: real 1
Description: The optical depth to reaionization in the instantReionization IGM state model.
Defined in: `function:instantReionizationIGMConstructorParameters`
File: `intergalactic_medium.state.instant_reionization.F90`
Used by:

Name: `element`
Type: string 0..1
Description: The atomic symbol for the element to use to define metallicity.
Defined in: `function:metallicityISMConstructorParameters`
File: `nodes.property_extractor.metallicity_ISM.F90`
Used by:

Name: `elementsToTrack`
Type: string 1..*
Description: The names of the elements to be tracked.
Defined in: `subroutine:Abundances_Initialize`
File: `objects.abundances.F90`
Used by:

Name: `emulateOutliers`
Type: boolean 1
Default value: .true.
Description: If true, then outlier chains are always emulated once the simulation is converged.
Defined in: `function:gaussianRegressionConstructorParameters`
File: `models.likelihoods.gaussian_regression.F90`
Used by:

Name: `emulatorRebuildCount`
Type: integer 1
Default value: 100
Description: The number of steps between rebuilds of the emulator.
Defined in: `function:gaussianRegressionConstructorParameters`
File: `models.likelihoods.gaussian_regression.F90`
Used by:

Name: `energyDistributionPointsPerDecade`
Type: real 0..1
Default value: 30.0
Description: The number of points per decade of radius to use when building the table of energy distribution function.
Defined in: `function:particulateConstructorParameters`
File: `merger_trees.operators.particulate.F90`
Used by:

Name: `energyEstimateParticleCountMaximum`
Type: real 1
Description: The maximum number of N-body particles used in estimating halo energies.
Defined in: `function:spinDistributionConstructorParameters`
File: `models.likelihoods.spin_distribution.F90`
Used by:

Name: `energyFixedAt`
Type: string 1
Default value: var_str('turnaround')
Description: Selects the epoch at which the energy of a spherical top hat perturbation in a dark energy cosmology should be "fixed" for the purposes of computing virial density contrasts. (See the discussion in Percival 2005; §8.)
Defined in: `function:sphericalCollapseMatterDEConstructorParameters`
File: `structure_formation.virial_density_contrast.spherical_collapse_matter_dark_energy.F90`
Used by:

Name: `energyOption`
Type: string 1
Default value: var_str('pureADAF')
Description: Specifies the specific energy of material at the inner edge of an ADAF. `pureADAF` makes the specific energy equal to 1 (i.e. all energy is advected with the flow); `ISCO` makes the specific energy equal to that for the innermost stable circular orbit.
Defined in: `function:adafConstructorParameters`
File: `accretion_disks.ADAF.F90`
Used by:

Name: `energyOrbital`
Type: real 1
Default value: 1.0
Description: The orbital energy in units of the characteristic orbital energy.
Defined in: `function:covington2008ConstructorParameters`

File: satellites.merging.remnant_sizes.Covington2008.F90
Used by:

Name: environmentAveraged
Type: boolean 1
Description: If true, the mass function will ve averaged over all environments.
Defined in: function:haloMassFunctionConstructorParameters
File: models.likelihoods.halo_mass_function.F90
Used by:

Name: epsilon
Type: real 1
Default value: 0.359 [Barkana et al., 2001, for the transfer function at $z = z_{\rm eq}$]
Description: The parameter ϵ appearing in the warm dark matter transfer function [Barkana et al., 2001].
Defined in: function:bode2001ConstructorParameters
File: structure_formation.transfer_function.Bode2001.F90
Used by:

Name: error
Type: real 1..*
Description: The errors on the magnitudes of the broad-band SED.
Defined in: function:sedFitConstructorParameters
File: models.likelihoods.SED_fit.F90
Used by:

Name: errorFractionalMaximum
Type: real 0..1
Description: Maximum allowed fractional error in halo mass.
Defined in: function:errorConvolvedConstructorParameters
File: structure_formation.halo_mass_function.error_convolved.F90
Used by:

Name: errorMaximum
Type: float 0..1
Description: The maximum error in the polynomial random error distribution class.
Defined in: function:randomErrorPolynomialConstructorParameters
File: galacticus.output.analyses.distribution_operator.random_error.polynomial.F90
Used by:

Name: errorMinimum
Type: float 0..1
Description: The minimum error in the polynomial random error distribution class.
Defined in: function:randomErrorPolynomialConstructorParameters
File: galacticus.output.analyses.distribution_operator.random_error.polynomial.F90
Used by:

Name: errorModel
Type: string 1

Description: The error model to use for the halo mass function.
Defined in: function:haloMassFunctionConstructorParameters
File: models.likelihoods.halo_mass_function.F90
Used by:

Name: errorWaitTime
Type: integer 1
Default value: 86400
Description: The time, in seconds, for which Galacticus should sleep after a fatal error when running under MPI.
Defined in: subroutine:Galacticus_Error_Wait_Set_From_Parameters
File: galacticus.error.wait.F90
Used by:

Name: essentialNodeID
Type: integer 1
Description: ID of the essential node to avoid pruning.
Defined in: function:pruneNonEssentialConstructorParameters
File: merger_trees.operators.prune_non_essential.F90
Used by:

Name: essentialNodeTime
Type: real 1
Description: Time of the essential node to avoid pruning.
Defined in: function:pruneNonEssentialConstructorParameters
File: merger_trees.operators.prune_non_essential.F90
Used by:

Name: eta
Type: real 1
Default value: 3.81 [Barkana et al., 2001, for the transfer function at $z = z_{\rm eq}$]
Description: The parameter ϵ appearing in the warm dark matter transfer function [Barkana et al., 2001].
Defined in: function:bode2001ConstructorParameters
File: structure_formation.transfer_function.Bode2001.F90
Used by:

Name: eta0
Type: real 1
Default value: 6.82
Description: The parameter η_0 appearing in the halo concentration algorithm of Diemer and Kravtsov [2014].
Defined in: function:diemerKravtsov2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Diemer-Kravtsov2014.F90
Used by:

Name: eta1
Type: real 1
Default value: 1.42

Description: The parameter η_1 appearing in the halo concentration algorithm of Diemer and Kravtsov [2014].
Defined in: function:diemerKravtsov2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Diemer-Kravtsov2014.F90
Used by:

Name: evolveForestsVerbosity
Type: integer 1
Default value: Galacticus_Verbosity_Level()
Description: The verbosity level to use while performing evolve forests tasks.
Defined in: function:galaxyPopulationConstructorParameters
File: models.likelihoods.galaxy_population.F90
Used by:

Name: evolveSingleForest
Type: boolean 1
Default value: .false.
Description: If true then each forest is processed sequentially, with multiple parallel threads (if available) working on the same forest. If false, multiple forests are processed simultaneously, with a single parallel thread (if available) working on each.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: evolveSingleForestMassMinimum
Type: integer 1
Default value: 0.0
Description: The minimum tree mass for which forests should be processed in parallel.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: evolveSingleForestSections
Type: integer 1
Default value: 100
Description: The number of timesteps into which forests should be split when processing single forests in parallel.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: exclusions
Type: string 1
Default value: [integer ::]
Description: List of parameter indices to exclude from the posterior likelihood calculation.
Defined in: function:posteriorAsPriorConstructorParameters
File: models.likelihoods.posterior_as_prior.F90
Used by:

Name: `expansionFactorEnd`
Type: real 1
Default value: 1.0
Description: Ending expansion factor to use when regridding merger trees.
Defined in: `function:regridTimesConstructorParameters`
File: `merger_trees.operators.regrid_times.F90`
Used by:

Name: `expansionFactorStart`
Type: real 1
Default value: 0.1
Description: Starting expansion factor to use when regridding merger trees.
Defined in: `function:regridTimesConstructorParameters`
File: `merger_trees.operators.regrid_times.F90`
Used by:

Name: `exponent`
Type: real 0..1
Default value: 0.8 Giocoli et al. [2008]
Description: The parameter α in the Giocoli et al. [2008] unevolved subhalo mass function fit.
Defined in: `function:giocoli2008ConstructorParameters`
File: `structure_formation.unevolved_subhalo_mass_function.Giocoli2008.F90`
Used by:

Name: `exponentAdjustFactor`
Type: real 1
Description: The factor by which to adjust the exponent.
Defined in: `function:adaptiveConstructorParameters`
File: `posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90`
Used by:

Name: `exponentCutOff`
Type: real 1
Default value: 1.0
Description: The exponent appearing in the exponential term for cooling timescale in the velocity maximum scaling scaling cooling rate model.
Defined in: `function:velocityMaximumScalingConstructorParameters`
File: `cooling.cooling_rate.velocity_maximum_scaling.F90`
Used by:

Name: `exponentExpansionFactor`
Type: real 1
Default value: 0.0
Description: The exponent for expansion factor in the Baugh et al. [2005] prescription for star formation in galactic disks.
Defined in: `function:baugh2005ConstructorParameters`
File: `star_formation.timescales.disks.Baugh2005.F90`
Used by:

Name: `exponentGas`
Type: real 1
Default value: 1.0000 [Shi et al., 2011]
Description: The exponent of gas surface density in the extended Schmidt star formation law.
Defined in: `function:extendedSchmidtConstructorParameters`
File: `star_formation.rate_surface_density.disks.extended_Schmidt.F90`
Used by:

Name: `exponentInitial`
Type: real 1
Description: The initial exponent.
Defined in: `function:adaptiveConstructorParameters`
File: `posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90`
Used by:

Name: `exponentMaximum`
Type: real 1
Description: The maximum allowed exponent.
Defined in: `function:adaptiveConstructorParameters`
File: `posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90`
Used by:

Name: `exponentMinimum`
Type: real 1
Description: The minimum allowed exponent.
Defined in: `function:adaptiveConstructorParameters`
File: `posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90`
Used by:

Name: `exponentRedshift`
Type: real 0..1
Default value: 0.0
Description: The exponent of redshift in the outflow rate in disks.
Defined in: `function:vlctyMxSclngConstructorParameters`
File: `star_formation.feedback.disks.velocity_maximum_scaling.F90`
Used by:

Name: `exponentStars`
Type: real 1
Default value: 0.4800 [Shi et al., 2011]
Description: The exponent of stellar surface density in the extended Schmidt star formation law.
Defined in: `function:extendedSchmidtConstructorParameters`
File: `star_formation.rate_surface_density.disks.extended_Schmidt.F90`
Used by:

Name: `exponentTruncated`
Type: real 1
Default value: 6.0
Description: The exponent of the $\Sigma_{\rm gas}/\Sigma_{\rm crit}$ term used in truncating the Kennicutt-Schmidt star for-

mation law.
Defined in: function:kennicuttSchmidtConstructorParameters
File: star_formation.rate_surface_density.disks.Kennicutt-Schmidt.F90
Used by:

Name: exponentValue
Type: real 1
Description: The exponent of temperature.
Defined in: function:fixedConstructorParameters
File: posterior_sampling.differential_proposal_size.temperature_exponent.fixed.F90
Used by:

Name: exponentVelocity
Type: real 0..1
Default value: -2.0d0
Description: The exponent of virial velocity in the outflow rate in disks.
Defined in: function:vlctyMxSclngConstructorParameters
File: star_formation.feedback.disks.velocity_maximum_scaling.F90
Used by:

Name: exponentVelocityVirial
Type: real 1
Default value: 0.0
Description: The exponent of virial velocity in the timescale for star formation in the halo scaling timescale model for disks.
Defined in: function:haloScalingConstructorParameters
File: star_formation.timescales.disks.halo_scaling.F90
Used by:

Name: exportFormat
Type: string 1
Default value: var_str('galacticus')
Description: The output format to use when exporting merger trees.
Defined in: function:exportConstructorParameters
File: merger_trees.operators.export.F90
Used by:

Name: extendedStatistics
Type: boolean 1
Default value: .true.
Description: Compute extended statistics (formation rate function, $N^{\rm th}$ most-massive progenitor mass functions, etc.)?
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: extentLower
Type: float 0..1
Default value: -huge(0.0d0)

Description: Lower extent for the normal distribution weight operator.
Defined in: function:normalConstructorParameters
File: galacticus.output.analyses.property_operator.normal.F90
Used by:

Name: extentUpper
Type: float 0..1
Default value: +huge(0.0d0)
Description: Upper extent for the normal distribution weight operator.
Defined in: function:normalConstructorParameters
File: galacticus.output.analyses.property_operator.normal.F90
Used by:

Name: extractApocenter
Type: boolean 1
Default value: .false.
Description: Specifies whether or not satellite orbital apocenter data (radius, velocity) should be extracted.
Defined in: function:satelliteOrbitalExtremaConstructorParameters
File: nodes.property_extractor.satellite_orbital_extrema.F90
Used by:

Name: extractPericenter
Type: boolean 1
Default value: .false.
Description: Specifies whether or not satellite orbital pericenter data (radius, velocity) should be extracted.
Defined in: function:satelliteOrbitalExtremaConstructorParameters
File: nodes.property_extractor.satellite_orbital_extrema.F90
Used by:

Name: f
Type: real 1
Default value: 1.0
Description: The parameter "f" which defines the scale of the Gaussian window.
Defined in: function:lagrangianChan2017ConstructorParameters
File: structure_formation.power_spectrum.variance.window_function.Lagrangian_Chan2017.F90
Used by:

Name: fSigma
Type: real 0..1
Default value: 0.4 [Obreschkow et al., 2009]
Description: The parameter, $\langle f_\sigma \rangle$, appearing in the model for the H_2/HI ratio in galaxies from Obreschkow et al. [2009].
Defined in: function:obreschkow2009ConstructorParameters
File: galacticus.output.analyses.molecular_ratio.Obreschkow2009.F90
Used by:

Name: factor

Type: real 0..1
Default value: 1.0
Description: The factor by which to rescale the excursion set barrier.
Defined in: function:remapScaleConstructorParameters
File: structure_formation.excursion_sets.barrier.remap.scale.F90
Used by:

Name: factorBoost
Type: float 1
Default value: 1.0
Description: The factor by which to boost satellite tidal fields in the sphericalSymmetry tidal field class.
Defined in: function:sphericalSymmetryConstructorParameters
File: satellites.tidal_fields.spherical_symmetry.F90
Used by:

Name: failedParametersFileName
Type: string 1
Default value: var_str('./failedParameters.xml')
Description: The filename to which parameters of failed models should be written.
Defined in: function:galaxyPopulationConstructorParameters
File: models.likelihoods.galaxy_population.F90
Used by:

Name: fast
Type: boolean 1
Default value: .true.
Description: Specifies whether or not to use simplifying assumptions to speed the hydrogen network calculation. If true, H^- is assumed to be at equilibrium abundance, H_2^+ reactions are ignored and other slow reactions are ignored (see Abel et al. 1997).
Defined in: function:hydrogenNetworkConstructorParameters
File: chemical.reaction_rates.hydrogen.F90
Used by:

Name: fatalMismatches
Type: boolean 1
Default value: .true.
Description: Specifies whether mismatches in cosmological parameter values between Galacticus and the merger tree file should be considered fatal.
Defined in: function:galacticusConstructorParameters
File: merger_trees.construct.read.importer.galacticus.F90
Used by:

Name: fatalNonTreeNode
Type: boolean 1
Default value: .true.
Description: Specifies whether nodes in snapshot files but not in the merger tree file should be considered fatal when importing from the "Sussing Merger Trees" format [Srisawat et al., 2013].
Defined in: function:sussingConstructorParameters

File: merger_trees.construct.read.importer.SussingMergerTrees.F90
Used by:

Name: fieldEnhancementOption
Type: string 1
Default value: var_str('exponential')
Description: Controls how the field enhancing shear is determined. exponential will cause the form $g = \exp(\omega t)$ [Benson and Babul, 2009] to be used, while linear will cause $g = 1 + \omega t$ to be used instead. The functional form of $\alpha(j)$ (if used) will be adjusted to achieve a sensible spin-up function in each case.
Defined in: function:adafConstructorParameters
File: accretion_disks.ADAF.F90
Used by:

Name: fileName
Type: string 0..1
Description: The name of the file from which to read a tabulated transfer function.
Defined in: function:fileConstructorParameters
File: structure_formation.transfer_function.file.F90
Used by:

Name: fileNames
Type: string 1..
Description: The name of the file(s) from which merger tree data should be read when using the [mergerTreeConstructMethod]=read tree construction method.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: filter
Type: string 1..*
Description: The names of the filters in the broad-band SED.
Defined in: function:sedFitConstructorParameters
File: models.likelihoods.SED_fit.F90
Used by:

Name: filterName
Type: string 0..1
Description: The filter to select.
Defined in: function:lmnstyStllrChrltFll2000ConstructorParameters
File: nodes.property_extractor.luminosity_stellar.dust.CharlotFall2000.F90
Used by:

Name: filterThreshold
Type: float 0..1
Description: Threshold for the high-pass filter distribution operator.
Defined in: function:filterHighPassConstructorParameters
File: galacticus.output.analyses.property_operator.filter.high_pass.F90
Used by:

Name: `filterType`
Type: string 0..1
Description: The filter type (rest or observed) to select.
Defined in: function:lmnstyStllrChrltFll2000ConstructorParameters
File: nodes.property_extractor.luminosity_stellar.dust.CharlotFall2000.F90
Used by:

Name: `finalLikelihoodFullEvaluation`
Type: boolean 1
Default value: .true.
Description: If true the final likelihood is evaluated fully, and not treated as a "lock in" likelihood.
Defined in: function:independentLikelihoodsSequentialConstructorParameters
File: models.likelihoods.independent_likelihoods.sequential.F90
Used by:

Name: `fitType`
Type: string 1
Default value: var_str('nfwVirial')
Description: The type of halo definition for which the concentration-mass relation should be computed. Allowed values are `nfwVirial`, `nfwMean200`, `einastoMean200`, and `userDefined`.
Defined in: function:duttonMaccio2014ConstructorParameters
File: dark_matter_profiles.structure.concentration.Dutton-Maccio2014.F90
Used by:

Name: `forceZeroMetallicity`
Type: boolean 0..1
Default value: .false.
Description: Force the use of zero metallicity (or lowest metallicity available) for all stellar populations.
Defined in: function:fileConstructorParameters
File: stellar_populations.spectra.file.F90
Used by:

Name: `forestFile`
Type: string 1
Default value: var_str('none')
Description: Name of file containing data on number of halos in each forest.
Defined in: function:sussingASCIIConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.ASCII.F90
Used by:

Name: `forestFirst`
Type: integer 1
Default value: 1
Description: Index of first forest to include.
Defined in: function:sussingASCIIConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.ASCII.F90
Used by:

Name: `forestLast`

Type: integer 1
Default value: -1
Description: Index of last forest to include.
Defined in: function:sussingASCIIConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.ASCII.F90
Used by:

Name: forestReverseSnapshotOrder
Type: integer 1
Default value: .false.
Description: If true, the order of forest snapshots will be reversed after being read. This may be necessary to cause them to match the order of snapshot files.
Defined in: function:sussingASCIIConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.ASCII.F90
Used by:

Name: forestSizeMaximum
Type: integer 1
Default value: 0_c_size_t
Description: The maximum number of nodes allowed in a forest before it will be broken up into trees and processed individually. A value of 0 implies that forests should never be split.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: formFactor
Type: real 1
Default value: 2.0
Description: The form factor appearing in the gravitational binding force (per unit area) in the ram pressure stripping model of Font et al. (2008; their eqn. 4).
Defined in: function:font2008ConstructorParameters
File: hot_halo.ram_pressure_stripping.Font2008.F90
Used by:

Name: formationRateTimeFraction
Type: real 1
Default value: 0.01
Description: The fraction of the current time over which to estimate the formation rate of halos when computing merger tree statistics.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: formationRedshift
Type: real 1
Description: The formation redshift to use in Wechsler et al. [2002] halo mass accretion histories.
Defined in: function:wechsler2002ConstructorParameters
File: dark_matter_halos.mass_accretion_history.Wechsler2002.F90
Used by:

Name: formationRedshiftCompute
Type: boolean 1
Default value: .true.
Description: If true, compute formation redshift automatically for Wechsler et al. [2002] halo mass accretion histories.
Defined in: function:wechsler2002ConstructorParameters
File: dark_matter_halos.mass_accretion_history.Wechsler2002.F90
Used by:

Name: formationTimeMassFraction
Type: double 1
Default value: 0.5
Description: Fractional mass of primary progenitor used to define formation time.
Defined in: subroutine:Node_Component_Formation_Times_Mass_Fraction_Initialize
File: objects.nodes.components.formation_times.mass_fraction.F90
Used by:

Name: formationTimeRecent
Type: real 0..1
Description: Halos which "formed" more recently than this time in the past will be excluded from the analysis.
Defined in: function:concentrationDistributionCDMCOCOConstructorParameters
File: galacticus.output.analyses.concentration_distribution.CDM.COCO.F90
Used by:

Name: fraction
Type: real 0..1
Default value: 0.01
Description: The ratio of outflow rate to star formation rate in disks.
Defined in: function:vlctyMxSclngConstructorParameters
File: star_formation.feedback.disks.velocity_maximum_scaling.F90
Used by:

Name: fractionGasCriticalBurst
Type: real 1
Default value: 0.75
Description: The host gas fraction above which mergers are considered to trigger a burst.
Defined in: function:baugh2005ConstructorParameters
File: satellites.merging.mass_movements.Baugh2005.F90
Used by:

Name: fractionalErrorHighMass
Type: real 0..1
Description: Parameter σ_∞ appearing in model for random errors in the halo mass function.
Defined in: function:nbodyHaloMassErrorPowerLawParameters
File: statistics.Nbody.halos.mass_errors.power_law.F90
Used by:

Name: `frequencyStarFormation`
Type: real 1
Default value: 0.385 [Krumholz et al., 2009]
Description: The star formation frequency (in units of Gyr^{-1}) in the "Krumholz-McKee-Tumlinson" star formation timescale calculation.
Defined in: `function:krumholz2009ConstructorParameters`
File: `star_formation.rate_surface_density.disks.Krumholz2009.F90`
Used by:

Name: `functionCovarianceTarget`
Type: real 0..1
Description: The target function covariance for likelihood calculations.
Defined in: `function:volumeFunction1DConstructorParameters`
File: `galacticus.output.analyses.volume_function_1d.F90`
Used by:

Name: `functionValueTarget`
Type: real 0..1
Description: The target function for likelihood calculations.
Defined in: `function:volumeFunction1DConstructorParameters`
File: `galacticus.output.analyses.volume_function_1d.F90`
Used by:

Name: `galacticusOutputFileName`
Type: string 1
Default value: var_str('galacticus.hdf5')
Description: The name of the file to which Galacticus results will be written.
Defined in: `subroutine:Galacticus_Output_Open_File`
File: `galacticus.output.HDF5.open.F90`
Used by:

Name: `galacticusOutputScratchFileName`
Type: string 1
Default value: galacticusOutputFileName
Description: The name of the file to which Galacticus results will be written temporarily during runs.
Defined in: `subroutine:Galacticus_Output_Open_File`
File: `galacticus.output.HDF5.open.F90`
Used by:

Name: `galaxyCatalogFileName`
Type: string 1
Description: The file name to which the galaxy catalog should be output.
Defined in: `function:haloModelGenerateConstructorParameters`
File: `tasks.halo_model_generate.F90`
Used by:

Name: `gamma`
Type: real 1

Description: The parameter γ of the Voight function.
Defined in: function:voightConstructorParameters
File: statistics.distributions.Voight.F90
Used by:

Name: gamma1
Type: real 1
Default value: 0.38
Description: The parameter γ_1 appearing in the modified merger rate expression of Parkinson et al. [2008].
Defined in: function:parkinsonColeHellyConstructorParameters
File: merger_trees.branching_probability.Parkinson_Cole_Helly.F90
Used by:

Name: gamma2
Type: real 1
Default value: -0.01d0
Description: The parameter γ_2 appearing in the modified merger rate expression of Parkinson et al. [2008].
Defined in: function:parkinsonColeHellyConstructorParameters
File: merger_trees.branching_probability.Parkinson_Cole_Helly.F90
Used by:

Name: gammaAdjustFactor
Type: real 1
Description: The factor by which to adjust the proposal size, γ.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.adaptive.F90
Used by:

Name: gammaInitial
Type: real 1
Description: The initial proposal size, γ.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.adaptive.F90
Used by:

Name: gammaMaximum
Type: real 1
Description: The maximum allowed proposal size, γ.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.adaptive.F90
Used by:

Name: gammaMinimum
Type: real 1
Description: The minimum allowed proposal size, γ.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.adaptive.F90

Used by:

Name: gammaRatioHigh
Type: real 1
Default value: [+0.071d0,+0.030d0,-0.012d0]
Description: Values of the γ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.05–0.5 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: gammaRatioIntermediate
Type: real 1
Default value: [+0.098d0,+0.087d0,+0.050d0]
Description: Values of the γ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.005–0.05 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: gammaRatioLow
Type: real 1
Default value: [+0.109d0,+0.114d0,+0.110d0]
Description: Values of the γ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.0001–0.005 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: gradientMaximum
Type: real 1
Description: The maximum acceptable gradient of acceptance rate with log-temperature.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90
Used by:

Name: gradientMinimum
Type: real 1
Description: The minimum acceptable gradient of acceptance rate with log-temperature.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90
Used by:

Name: halfIntegral
Type: string 1
Default value: .false.
Description: Set to `true` if the projected correlation function is computed as $w_\mathrm{p}(r_\mathrm{p}) = \int_0^{+\pi_\mathrm{max}} \xi(r_\mathrm{p},\pi)\mathrm{d}\pi$, instead of the usual $w_\mathrm{p}(r_\mathrm{p}) = \int_{-\pi_\mathrm{max}}^{+\pi_\mathrm{max}} \xi(r_\mathrm{p},\pi)\mathrm{d}\pi$.
Defined in: function:haloModelProjectedCorrelationFunctionConstructorParameters

File: tasks.halo_model.projected_correlation_function.F90
Used by:

Name: haloCatalogFileName
Type: string 1
Description: The file name of the halo catalog to populate.
Defined in: function:haloModelGenerateConstructorParameters
File: tasks.halo_model_generate.F90
Used by:

Name: haloIdToParticleType
Type: boolean 0..1
Default value: .false.
Description: If true, the halo ID will be used to assign particles from each halo to a different Gadget particle type group.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: haloMassMaximum
Type: real 1
Default value: 1.0×10^{15}
Description: The maximum mass at which to tabulate halo mass functions.
Defined in: function:haloMassFunctionConstructorParameters
File: tasks.halo_mass_function.F90
Used by:

Name: haloMassMinimum
Type: real 0..1
Default value: 0.0
Description: Minimum halo mass above which spin distribution should be averaged.
Defined in: function:haloSpinDistributionConstructorParameters
File: tasks.halo_spin_distribution.F90
Used by:

Name: haloMassesIncludeSubhalos
Type: boolean 1
Description: Specifies whether or not halo masses include the masses of their subhalos.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: haloModelWavenumberMaximum
Type: real 1
Default value: 1.0×10^{4}
Description: The maximum wavenumber (in Mpc^{-}1) at which to tabulate power spectra for the halo model.
Defined in: subroutine:Galacticus_Output_Halo_Model_Initialize
File: galacticus.output.merger_tree.halo_model.F90

Used by:

Name: haloModelWavenumberMinimum
Type: real 1
Default value: 1.0×10^{-3}
Description: The minimum wavenumber (in Mpc$^-$1) at which to tabulate power spectra for the halo model.
Defined in: subroutine:Galacticus_Output_Halo_Model_Initialize
File: galacticus.output.merger_tree.halo_model.F90
Used by:

Name: haloModelWavenumberPointsPerDecade
Type: integer 1
Default value: 10
Description: The number of points per decade in wavenumber at which to tabulate power spectra for the halo model.
Defined in: subroutine:Galacticus_Output_Halo_Model_Initialize
File: galacticus.output.merger_tree.halo_model.F90
Used by:

Name: haloReformationMassFactor
Type: double 1
Default value: 2.0
Description: Factor by which halo mass must have increased to trigger a new formation event.
Defined in: subroutine:Node_Component_Formation_Times_Cole2000_Initialize
File: objects.nodes.components.formation_times.Cole2000.F90
Used by:

Name: haloReformationOnPromotionOnly
Type: boolean 1
Default value: .false.
Description: Specifies whether halo reformation should occur only at node promotion events, or at the precise time that the halo mass has increased sufficiently in mass.
Defined in: subroutine:Node_Component_Formation_Times_Cole2000_Initialize
File: objects.nodes.components.formation_times.Cole2000.F90
Used by:

Name: hdf5CacheElementsCount
Type: boolean 1
Default value: 521_size_t
Description: Number of elements in the raw data chunk cache.
Defined in: subroutine:Galacticus_Output_Open_File
File: galacticus.output.HDF5.open.F90
Used by:

Name: hdf5CacheSizeBytes
Type: boolean 1
Default value: 1048576_size_t
Description: Size of the raw data chunk cache in bytes.

Defined in: subroutine:Galacticus_Output_Open_File
File: galacticus.output.HDF5.open.F90
Used by:

Name: hdf5ChunkSize
Type: integer 1
Default value: 1024_hsize_t
Description: The chunk size used for outputting HDF5 datasets.
Defined in: subroutine:Galacticus_Output_Open_File
File: galacticus.output.HDF5.open.F90
Used by:

Name: hdf5CompressionLevel
Type: integer 1
Default value: -1
Description: The compression level used for outputting HDF5 datasets.
Defined in: subroutine:Galacticus_Output_Open_File
File: galacticus.output.HDF5.open.F90
Used by:

Name: hdf5SieveBufferSize
Type: integer 1
Default value: 65536
Description: The size of the sieve buffer used by the HDF5 library to speed reading/writing of partial datasets.
Defined in: subroutine:Galacticus_Output_Open_File
File: galacticus.output.HDF5.open.F90
Used by:

Name: hdf5UseLatestFormat
Type: boolean 1
Default value: .false.
Description: Specifies whether to use the latest HDF5 file format.
Defined in: subroutine:Galacticus_Output_Open_File
File: galacticus.output.HDF5.open.F90
Used by:

Name: heightToRadialScaleDisk
Type: real 1
Default value: 0.137 [Kregel et al., 2002]
Description: The ratio of scale height to scale radius for disks in the "Blitz-Rosolowsky2006" star formation timescale calculation.
Defined in: function:blitz2006ConstructorParameters
File: star_formation.rate_surface_density.disks.Blitz2006.F90
Used by:

Name: hierarchyDepth
Type: integer 1
Default value: 1

Description: The depth in the substructure hierarchy at which to prune a tree.
Defined in: function:pruneHierarchyConstructorParameters
File: merger_trees.operators.prune_hierarchy.F90
Used by:

Name: hierarchyLevelResetFactor
Type: double 1
Default value: 1.0×10^{100}
Description: The factor by which a node's mass must increase before the previous maximum hierarchy level is forgotten.
Defined in: subroutine:Node_Component_Merging_Statistics_Standard_Initialize
File: objects.nodes.components.merging_statistics.standard.F90
Used by:

Name: historyCount
Type: integer 1
Default value: 30
Description: The number of steps (spaced logarithmically in cosmic time) at which to tabulate the volume averaged history of galaxies.
Defined in: function:historyConstructorParameters
File: merger_trees.evolve.timesteps.history.F90
Used by:

Name: hotHaloAngularMomentumAlwaysGrows
Type: boolean 1
Default value: .false.
Description: Specifies whether or not negative rates of accretion of angular momentum into the hot halo will be treated as positive for the purposes of computing the hot halo angular momentum.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: hotHaloAngularMomentumLossFraction
Type: double 1
Default value: 0.3
Description: Specifies the fraction of angular momentum that is lost from cooling/infalling gas.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: hotHaloCoolingFromNode
Type: integer 1
Default value: var_str('currentNode')
Description: Specifies whether the angular momentum of cooling gas should be computed from the "current node" or the "formation node".
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: `hotHaloExcessHeatDrivesOutflow`
Type: integer 1
Default value: .true.
Description: Specifies whether heating of the halo in excess of its cooling rate will drive an outflow from the halo.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: `hotHaloExpulsionRateMaximum`
Type: double 1
Default value: 1.0
Description: Specifies the maximum rate at which mass can be expelled from the hot halo in units of the inverse halo dynamical time.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: `hotHaloNodeMergerLimitBaryonFraction`
Type: boolean 1
Default value: .false.
Description: Controls whether the hot gas content of nodes should be limited to not exceed the universal baryon fraction at node merger events. If set to `true`, hot gas (and angular momentum, abundances, and chemicals proportionally) will be removed from the merged halo to the unaccreted gas reservoir to limit the baryonic mass to the universal baryon fraction where possible.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: `hotHaloOutflowReturnOnFormation`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not outflowed gas should be returned to the hot reservoir on halo formation events.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: `hotHaloOutflowStrippingEfficiency`
Type: double 1
Default value: 0.1
Description: Specifies the efficiency with which outflowing gas is stripped from the hot halo, following the prescription of Font et al. (2008; i.e. this is the parameter $\epsilon_{\rm strip}$ in their eqn. 6).
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: `hotHaloOutflowToColdMode`
Type: boolean 1

Default value: .false.
Description: Specifies whether or not outflows from galaxies are returned to the cold or hot modes in the hot halo.
Defined in: subroutine:Node_Component_Hot_Halo_Cold_Mode_Initialize
File: objects.nodes.components.hot_halo.cold_mode.F90
Used by:

Name: hotHaloTrackStrippedGas
Type: boolean 1
Default value: .true.
Description: Specifies whether or not gas stripped from the hot halo should be tracked.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: hotHaloVerySimpleDelayedMassScaleRelative
Type: double 1
Default value: 1.0×10^{-2}
Description: The mass scale, relative to the total mass of the node, below which calculations in the delayed very simple hot halo component are allowed to become inaccurate.
Defined in: subroutine:Node_Component_Hot_Halo_VS_Delayed_Initialize
File: objects.nodes.components.hot_halo.very_simple_delayed.F90
Used by:

Name: hubbleExponent
Type: integer 1
Description: The exponent of the "little-h" Hubble parameter needed to convert the velocities to little-h-free units.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: hypergeometricTabulate
Type: boolean 1
Default value: .true.
Description: Specifies whether hypergeometric factors should be precomputed and tabulated in modified Press-Schechter tree branching functions.
Defined in: function:parkinsonColeHellyConstructorParameters
File: merger_trees.branching_probability.Parkinson_Cole_Helly.F90
Used by:

Name: idMultiplier
Type: real 0..1
Default value: 0_kind_int8
Description: If this parameter is greater than zero, particle IDs begin at nodeIndex[idMultiplier] for each node. The multiplier should be chosen to be large enough that duplicate IDs can not occur.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: `ignoreChainNumberAdvice`
Type: logical 1
Default value: .false.
Description: If true, ignore warnings and errors about not being able to span the full parameter space with the number of chains used.
Defined in: `function:differentialEvolutionConstructorParameters`
File: `posterior_sampling.simulation.differential_evolution.F90`
Used by:

Name: `includeAngularCoordinates`
Type: boolean 0..1
Default value: .false.
Description: If true output angular coordinates in the lightcone.
Defined in: `function:lightconeConstructorParameters`
File: `nodes.property_extractor.lightcone.F90`
Used by:

Name: `includeBaryonGravity`
Type: boolean 1
Default value: .true.
Description: Specifies whether or not gravity from baryons is included when solving for sizes of galactic components in equilibriumally contracted dark matter halos.
Defined in: `function:equilibriumConstructorParameters`
File: `galactic_structure.radius_solver.equilibrium.F90`
Used by:

Name: `includeHalo`
Type: boolean 1
Default value: .true.
Description: Specifies whether or not to include the halo contribution to mass function covariance matrices.
Defined in: `function:massFunctionCovarianceConstructorParameters`
File: `tasks.mass_function_covariance.F90`
Used by:

Name: `includeLSS`
Type: boolean 1
Default value: .true.
Description: Specifies whether or not to include the large-scale structure contribution to mass function covariance matrices.
Defined in: `function:massFunctionCovarianceConstructorParameters`
File: `tasks.mass_function_covariance.F90`
Used by:

Name: `includeNitrogenII`
Type: real 0..1
Default value: .false.
Description: If true, include contimination by the [NII] (6548Å+ 6584Å) doublet.

Defined in: function:luminosityFunctionHalphaConstructorParameters
File: galacticus.output.analyses.luminosity_function.Halpha.F90
Used by:

Name: includeNonLinear
Type: integer 1
Default value: .false.
Description: If true the nonlinear power spectrum is also computed and output.
Defined in: function:powerSpectraConstructorParameters
File: tasks.power_spectrum.F90
Used by:

Name: includeObservedRedshift
Type: boolean 0..1
Default value: .false.
Description: If true output the observed redshfit (i.e. including the effects of pecular velocities).
Defined in: function:lightconeConstructorParameters
File: nodes.property_extractor.lightcone.F90
Used by:

Name: includePoisson
Type: boolean 1
Default value: .true.
Description: Specifies whether or not to include the Poisson contribution to mass function covariance matrices.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: includeRadii
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the radii at which velocity dispersion data are output should also be included in the output file.
Defined in: function:velocityDispersionConstructorParameters
File: nodes.property_extractor.velocity_dispersion.F90
Used by:

Name: includeSpin
Type: boolean 1
Default value: .false.
Description: If true, include the spin of the halo in the output.
Defined in: function:massAccretionHistoryConstructorParameters
File: merger_trees.operators.mass_accretion_history.F90
Used by:

Name: includeSpinVector
Type: boolean 1
Default value: .false.

Description: If true, include the spin vector of the halo in the output.
Defined in: function:massAccretionHistoryConstructorParameters
File: merger_trees.operators.mass_accretion_history.F90
Used by:

Name: includesHubbleFlow
Type: boolean 1
Description: Specifies whether or not Hubble flow is included in velocities.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: index
Type: real 0..1
Default value: 0.9649 (Planck Collaboration et al. 2018; TT,TE,EE+lowE+lensing)
Description: The index of the power-law primordial power spectrum.
Defined in: function:powerLawConstructorParameters
File: structure_formation.power_spectrum.primordial.power_law.F90
Used by:

Name: inertiaWeight
Type: real 1
Default value: 0.72
Description: Inertia parameter.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: initialMassForSupernovaeTypeII
Type: real 1
Default value: 8.0
Description: The minimum mass that a star must have in order that is result in a Type II supernova.
Defined in: function:standardConstructorParameters
File: stellar_astrophysics.feedback.standard.F90
Used by:

Name: initializeNodeClassHierarchy
Type: boolean 1
Default value: .true.
Description: If true then initialize the node class hierarchy in the posterior sampling class. This should be set to false if the likelihood function will instead perform this action.
Defined in: function:posteriorSampleConstructorParameters
File: tasks.posterior_sample.F90
Used by:

Name: inputFileName
Type: string 1
Description: The name of the file from which to read merger tree data.
Defined in: function:mergerTreeFileBuilderConstructorParameters

File: tasks.merger_tree_file_builder.F90
Used by:

Name: instantaneousRecyclingApproximation
Type: boolean 1
Default value: .false.
Description: If true, then use an instantaneous recycling approximation when computing recycling, yield, and energy input rates.
Defined in: function:standardConstructorParameters
File: stellar_populations.standard.F90
Used by:

Name: integralConstraint
Type: real 0..1
Description: The integral constraint for these correlation functions.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: interactionRoot
Type: integer 1
Default value: var_str('none')
Description: Root file name for interaction files, or '**none**' if interaction is not required.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: inverseSigma0
Type: real 1
Default value: 1.047 Prada et al. [2011]
Description: The parameter σ_0^{-1} appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: inverseSigma1
Type: real 1
Default value: 1.646 Prada et al. [2011]
Description: The parameter σ_1^{-1} appearing in the halo concentration algorithm of Prada et al. [2011].
Defined in: function:prada2011ConstructorParameters
File: dark_matter_profiles.structure.concentration.Prada2011.F90
Used by:

Name: kappa
Type: real 1
Default value: 0.69
Description: The parameter κ appearing in the halo concentration algorithm of Diemer and Kravtsov [2014].
Defined in: function:diemerKravtsov2014ConstructorParameters

File: dark_matter_profiles.structure.concentration.Diemer-Kravtsov2014.F90
Used by:

Name: kernelSoftening
Type: string 0..1
Default value: var_str('plummer')
Description: Selects the softening kernel to use. Allowed options are "plummer", and "gadget".
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: label
Type: string 0..1
Description: A label for the analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: lambda0
Type: real 1
Default value: 0.04326 [Bett et al., 2007]
Description: The parameter λ_0 in the halo spin distribution of Bett et al. [2007].
Defined in: function:bett2007ConstructorParameters
File: dark_matter_halos.spins.distributions.Bett2007.F90
Used by:

Name: lengthBox
Type: real 0..1
Default value: 0.0
Description: The length of the periodic box.
Defined in: function:environmentalOverdensityConstructorParameters
File: nBody.operator.environmental_overdensity.F90
Used by:

Name: lengthHubbleExponent
Type: real 0..1
Description: The exponent of the "little-h" parameter used in the definition of the box length.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: lengthReplication
Type: real 0..1
Description: The length of the simulation box being used to construct the lightcone.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: lengthSoftening

Type: boolean 0..1
Default value: 0.0
Description: The Plummer-equivalent softening length. That is, the parameter ϵ in the softening gravitational potential $\phi(r) = -\mathrm{G}m/\sqrt{r^2+\epsilon^2}$. If set to zero, softening is ignored when constructing the particle representation of the halo. For non-zero values softening is accounted for when constructing the velocity distribution following the procedure of Barnes [2012].
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: lengthUnitsInSI
Type: real 0..1
Description: The units of the box length in the SI system.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: likelihoodBin
Type: integer 0..1
Default value: 0_c_size_t
Description: If > 0 then use only the mass bin given by this value in the likelihood calculation.
Defined in: function:stellarVsHaloMassRelationLeauthaud2012ConstructorParameters
File: galacticus.output.analyses.stellar_vs_halo_mass_relation.COSMOS_Leauthaud2012.F90
Used by:

Name: likelihoodNormalize
Type: boolean 0..1
Default value: .true.
Description: If true then normalize the likelihood to make it a probability density.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: likelihoodThreshold
Type: real 1
Default value: 0.0
Description: The threshold log-likelihood above which convergence is declared.
Defined in: function:likelihoodThresholdConstructorParameters
File: posterior_sampling.convergence.likelihood_threshold.F90
Used by:

Name: limit
Type: string 1
Description: Limiting surface brightness for mass function incompleteness calculations.
Defined in: function:surfaceBrightnessConstructorParameters
File: statistics.mass_function.incompleteness.surface_brightness.F90
Used by:

Name: limitLoadAverage

Type: boolean 1
Default value: .false.
Description: Specifies whether or not to limit the load average
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: limitLower
Type: real 1
Description: The lower limit of the uniform distribution.
Defined in: function:uniformConstructorParameters
File: statistics.distributions.uniform.F90
Used by:

Name: limitUpper
Type: real 1
Description: The upper limit of the uniform distribution.
Defined in: function:uniformConstructorParameters
File: statistics.distributions.uniform.F90
Used by:

Name: lineNames
Type: string 0..1
Description: The emission lines to extract.
Defined in: function:lmnstyEmssnLineConstructorParameters
File: nodes.property_extractor.luminosity_emission_line.F90
Used by:

Name: lineOfSightDepth
Type: real 1
Description: The line of sight depth over which to integrate.
Defined in: function:projectedCorrelationFunctionConstructorParameters
File: models.likelihoods.projected_correlation_function.F90
Used by:

Name: linkingLength
Type: real 0..1
Description: The linking length (in physical Mpc) used in the friends-of-friends algorithm.
Defined in: function:fofBiasConstructorParameters
File: structure_formation.halo_mass_function.friends_of_friends_bias.F90
Used by:

Name: linkingLengthIsComoving
Type: boolean 0..1
Description: Specifies whether or not the given linking length is in comoving units.
Defined in: function:fofBiasConstructorParameters
File: structure_formation.halo_mass_function.friends_of_friends_bias.F90
Used by:

Name: `loadAverageMaximum`
Type: boolean 1
Default value: var_str('processorCount')
Description: The maximum load average for which new trees will be processed.
Defined in: `function:evolveForestsConstructorParameters`
File: `tasks.evolve_forests.F90`
Used by:

Name: `loadBalance`
Type: logical 1
Default value: .true.
Description: If true, attempt to balance the workload across different compute nodes.
Defined in: `function:differentialEvolutionConstructorParameters`
File: `posterior_sampling.simulation.differential_evolution.F90`
Used by:

Name: `lockFileGlobally`
Type: boolean 1
Default value: .false.
Description: If true, attempt to lock the CAMB transfer function file before accessing. Otherwise, no locking is attempted.
Defined in: `function:cambConstructorParameters`
File: `structure_formation.transfer_function.CAMB.F90`
Used by:

Name: `log10M1`
Type: real 1
Default value: 12.520 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $\log_{10} M_1$ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `log10Mstar0`
Type: real 1
Default value: 10.916 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $\log_{10} M_{\star,0}$ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `logFileName`
Type: real 1
Description: The name of the file to which convergence state should be logged.
Defined in: `function:gelmanRubinConstructorParameters`
File: `posterior_sampling.convergence.Gelman-Rubin.F90`
Used by:

Name: `logFilePreviousRoot`

Type: integer 1
Default value: var_str('none')
Description: Root file name for log files from which to resume.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: logFileRoot
Type: integer 1
Description: Root file name for log files.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: logFlushCount
Type: integer 1
Default value: 10
Description: The number of steps between flushing the log file.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: logLikelihoodBuffer
Type: real 1
Default value: 10.0
Description: The buffer size in log-likelihood to use when deciding whether to emulate the likelihood.
Defined in: function:gaussianRegressionConstructorParameters
File: models.likelihoods.gaussian_regression.F90
Used by:

Name: logLikelihoodErrorTolerance
Type: real 1
Default value: 0.1
Description: The tolerance on the likelihood error to accept when deciding whether to emulate the likelihood.
Defined in: function:gaussianRegressionConstructorParameters
File: models.likelihoods.gaussian_regression.F90
Used by:

Name: logM0
Type: real 0..1
Default value: 10.0
Description: The parameter $\log_{10} M_0$ (with M_0 in units of $M_\odot$) appearing in the star formation rate threshold expression for the star formation rate galactic filter class.
Defined in: function:starFormationRateConstructorParameters
File: galactic.filters.star_formation_rate.F90
Used by:

Name: logSFR0

Type: real 0..1
Default value: 9.0
Description: The parameter α_0 appearing in the star formation rate threshold expression for the star formation rate galactic filter class.
Defined in: function:starFormationRateConstructorParameters
File: galactic.filters.star_formation_rate.F90
Used by:

Name: logSFR1
Type: real 0..1
Default value: 0.0
Description: The parameter α_1 appearing in the star formation rate threshold expression for the star formation rate galactic filter class.
Defined in: function:starFormationRateConstructorParameters
File: galactic.filters.star_formation_rate.F90
Used by:

Name: logarithmCoulomb
Type: real 1
Default value: 2.0
Description: The Coulomb logarithm, $\ln \Lambda$, appearing in the Chandrasekhar [1943] formulation of the acceleration due to dynamical friction.
Defined in: function:chandrasekhar1943ConstructorParameters
File: satellites.dynamical_friction.acceleration.Chandrasekhar1943.F90
Used by:

Name: luminosities
Type: float 0..1
Description: The luminosities corresponding to bin centers.
Defined in: function:luminosityFunctionHalphaConstructorParameters
File: galacticus.output.analyses.luminosity_function.Halpha.F90
Used by:

Name: luminosityBandRedshift
Type: real 0..*
Description: If present, force filters to be shifted to this redshift rather than that specified by [luminosityRedshift]. Allows sampling of the SED at wavelengths corresponding to other redshifts.
Defined in: subroutine:Stellar_Luminosities_Initialize
File: objects.stellar_luminosities.F90
Used by:

Name: luminosityFilter
Type: string 0..*
Description: The filter name for each stellar luminosity to be computed.
Defined in: subroutine:Stellar_Luminosities_Initialize
File: objects.stellar_luminosities.F90
Used by:

Name: luminosityOutputOption

Type: integer 1
Default value: var_str('present')
Description: Selects which luminosities will be output at each output time:

all Output all luminosities;

future Output only those luminosities computed for the present output or future times;

present Output only those luminosities computed for the present output time.

Defined in: subroutine:Stellar_Luminosities_Initialize
File: objects.stellar_luminosities.F90
Used by:

Name: luminosityPostprocessSet
Type: string 0..*
Description: The name of the set of postprocessing algorithms to apply to this filter.
Defined in: subroutine:Stellar_Luminosities_Initialize
File: objects.stellar_luminosities.F90
Used by:

Name: luminosityRedshift
Type: real 0..*
Description: The redshift for which to compute each specified stellar luminosity.
Defined in: subroutine:Stellar_Luminosities_Initialize
File: objects.stellar_luminosities.F90
Used by:

Name: luminosityType
Type: string 0..*
Description: The luminosity type for each stellar luminosity to be computed:

rest Compute luminosity in the galaxy rest frame;

observed Compute luminosity in the observer frame[1].

Defined in: subroutine:Stellar_Luminosities_Initialize
File: objects.stellar_luminosities.F90
Used by:

Name: magnitude
Type: real 1..*
Description: The magnitudes of the broad-band SED.
Defined in: function:sedFitConstructorParameters
File: models.likelihoods.SED_fit.F90
Used by:

Name: magnitudesAbsolute
Type: float 0..1

[1] The luminosity computed in this way is that in the galaxy rest frame using a filter blueshifted to the galaxy's redshift. This means that to compute an apparent magnitude you must add not only the distance modulus, but a factor of $-2.5\log_{10}(1+z)$ to account for compression of photon frequencies.

Description: The absolute magnitudes corresponding to bin centers.
Defined in: function:luminosityFunctionConstructorParameters
File: galacticus.output.analyses.luminosity_function.F90
Used by:

Name: mass
Type: real 1..*
Default value: [0.1d0,125.0d0]
Description: The mass points used to define a piecewise power-law initial mass function.
Defined in: function:piecewisePowerLawConstructorParameters
File: stellar_populations.initial_mass_functions.piecewise_power_law.F90
Used by:

Name: massBinCenters
Type: real 1
Description: Logarithmic mass bins centers for conditional mass function calculations.
Defined in: function:conditionalMassFunctionConstructorParameters
File: tasks.conditional_mass_function.F90
Used by:

Name: massBinsPerDecade
Type: integer 1
Default value: 10
Description: The number of bins per decade of non-primary progenitor mass.
Defined in: function:profilerConstructorParameters
File: merger_trees.operators.profiler.F90
Used by:

Name: massCharacteristic
Type: real 1
Default value: 0.08
Description: Characteristic mass of the lognormal part of the Chabrier [2001] initial mass function (IMF).
Defined in: function:chabrier2001ConstructorParameters
File: stellar_populations.initial_mass_functions.Chabrier2001.F90
Used by:

Name: massCutOff
Type: double precision 0..
Default value: 1.0×10^{10}
Description: For the augment operator a description of resolution limit for new trees.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: massCutOffAttemptsMaximum
Type: integer 0..
Default value: 50
Description: The number of trees with nodes above the mass resolution to allow before adjusting the

mass cut-off tolerance.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: massCutOffScaleFactor
Type: real 0..
Default value: 0.05
Description: The amount by which to increase the mass cut-off scale tolerance after exhausting tree build attempts.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: massElement
Type: float 0..1
Description: The atomic mass of the element used to define metallicity.
Defined in: function:metallicity12LogNHConstructorParameters
File: galacticus.output.analyses.property_operator.metallicity.F90
Used by:

Name: massFlowStatisticsResetOnOutput
Type: double 1
Default value: .true.
Description: Specifies whether or not mass flow statistics should be reset to zero at each output.
Defined in: subroutine:Node_Component_Mass_Flow_Statistics_Standard_Initialize
File: objects.nodes.components.mass_flow_statistics.standard.F90
Used by:

Name: massFractionFormation
Type: real 1
Default value: 0.05
Description: The fraction of a halo's mass assembled at "formation" in the halo concentration algorithm of Schneider [2015].
Defined in: function:schneider2015ConstructorParameters
File: dark_matter_profiles.structure.concentration.Schneider2015.F90
Used by:

Name: massFunctionFileName
Type: string 1
Description: The name of the file to which the covariance matrix should be written.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: massFunctionType
Type: string 1
Description: The type of mass function () model to use.
Defined in: function:haloMassFunctionConstructorParameters

File: models.likelihoods.halo_mass_function.F90
Used by:

Name: massHalo
Type: string 1
Default value: var_str('all')
Description: The halo mass for which to compute the conditional mass function. A value of "all" will cause the conditional mass function to be integrated over the halo mass function, giving the mass function.
Defined in: function:conditionalMassFunctionConstructorParameters
File: tasks.conditional_mass_function.F90
Used by:

Name: massHaloBinsPerDecade
Type: real 0..1
Default value: 10
Description: The number of bins per decade of halo mass to use when constructing the mass function covariance matrix for main branch galaxies.
Defined in: function:correlationFunctionHearin2013SDSSConstructorParameters
File: galacticus.output.analyses.correlation_function.Hearin2014_SDSS.F90
Used by:

Name: massHaloDeclineFactor
Type: real 1
Default value: 0.9
Description: The factor by which halo mass should decrease in each step back in time building a smoothly accreting merger tree, in units of $M_\odot$.
Defined in: function:smoothAccretionConstructorParameters
File: merger_trees.construct.smooth_accretion.F90
Used by:

Name: massHaloMaximum
Type: boolean 1
Default value: 1.0×10^{15}
Description: The minimum halo mass to use when computing mass function covariance matrices.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: massHaloMinimum
Type: float 1
Default value: 1.0×10^{10}
Description: The minimum halo mass to use when computing mass function covariance matrices.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: massHaloResolution
Type: real 1

Default value: 1.0×10^9
Description: The final mass of the merger tree base halo to consider when building a smoothly accreting merger tree, in units of $M_\odot$.
Defined in: function:smoothAccretionConstructorParameters
File: merger_trees.construct.smooth_accretion.F90
Used by:

Name: massInfiniteToMassSharpEdge
Type: real 0..1
Default value: 0.98 [More et al., 2011, estimate based on comments in text]
Description: The ratio of the friends-of-friends mass in the limit of infinite number of particles to the mass of the halo enclosed within a sharp-edged sphere bounding an isodensity surface equal to the critical density for percolation.
Defined in: function:fofBiasConstructorParameters
File: structure_formation.halo_mass_function.friends_of_friends_bias.F90
Used by:

Name: massIntervalFractional
Type: float 1
Default value: 0.1
Description: The fractional mass interval occupied by the trees. Where the intervals of trees of different mass would overlap this interval will be truncated.
Defined in: function:readXMLConstructorParameters
File: merger_trees.construct.build.masses.read.XML.F90
Used by:

Name: massLoading
Type: real 0..1
Default value: 2.0
Description: The mass-loading of "superwind" expulsive outflows in spheroids..
Defined in: function:superWindConstructorParameters
File: star_formation.feedback_expulsion.spheroids.superwind.F90
Used by:

Name: massLogarithmDelta
Type: real 1
Description: Logarithmic widths of mass bins for conditional mass function calculations.
Defined in: function:conditionalMassFunctionConstructorParameters
File: tasks.conditional_mass_function.F90
Used by:

Name: massLongLived
Type: real 1
Default value: 1.0
Description: The mass below which stars are assumed to be infinitely long-lived in the instantaneous approximation for stellar evolution.
Defined in: function:standardConstructorParameters
File: stellar_populations.standard.F90
Used by:

Name: massLower
Type: real 1
Default value: 0.1
Description: The lower mass limit for the Chabrier [2001] IMF.
Defined in: function:chabrier2001ConstructorParameters
File: stellar_populations.initial_mass_functions.Chabrier2001.F90
Used by:

Name: massMaxima
Type: float 0..1
Description: The maximum mass of each mass sample.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: massMaximum
Type: float 1
Default value: 1.0×10^{13}
Description: The maximum mass in the mass function for covariance calculations.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: massMinima
Type: float 0..1
Description: The minimum mass of each mass sample.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: massMinimum
Type: float 1
Default value: 1.0×10^{08}
Description: The minimum mass in the mass function for covariance calculations.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: massOptions
Type: string 1
Default value: var_str('default')
Description: Mass option for Sussing merger trees.
Defined in: function:sussingConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.F90
Used by:

Name: massOvershootAttemptsMaximum
Type: integer 0..

Default value: 50
Description: The number of failed trees to allow before increasing the mass of the parent node.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: massOvershootScaleFactor
Type: real 0..
Default value: 0.05
Description: The amount by which to increase the mass overshoot factor after exhausting tree build attempts.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: massParticle
Type: real 1
Description: The mass of the simulation particle.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: massRangeMinimum
Type: real 1
Description: The minimum halo mass to include in the likelihood evaluation.
Defined in: function:haloMassFunctionConstructorParameters
File: models.likelihoods.halo_mass_function.F90
Used by:

Name: massRatioCount
Type: integer 1
Default value: 10
Description: The number of bins in mass ratio when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: massRatioMajorMerger
Type: real 1
Default value: 0.25
Description: The mass ratio above which mergers are considered to be "major".
Defined in: function:verySimpleConstructorParameters
File: satellites.merging.mass_movements.very_simple.F90
Used by:

Name: massRatioMaximum
Type: logical 1
Default value: 1.0×10^{1}
Description: The maximum mass ratio to bin when constructing conditional halo mass functions.

Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: massRatioMinimum
Type: real 1
Default value: 1.0×10^{-4}
Description: The minimum mass ratio to bin when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: massResolution
Type: real 0..1
Default value: 5.0×10^{9}
Description: The mass resolution to use when building merger trees.
Defined in: function:fixedConstructorParameters
File: merger_trees.construct.build.mass_resolution.fixed.F90
Used by:

Name: massResolutionFractional
Type: real 0..1
Default value: 1.0×10^{-3}
Description: The fraction of the tree's root node mass to be used for the mass resolution when building merger trees.
Defined in: function:scaledConstructorParameters
File: merger_trees.construct.build.mass_resolution.scaled.F90
Used by:

Name: massResolutionMaximum
Type: real 0..1
Default value: huge(0.0d0)
Description: The maximum mass resolution to use when building merger trees.
Defined in: function:scaledConstructorParameters
File: merger_trees.construct.build.mass_resolution.scaled.F90
Used by:

Name: massResolutionMinimum
Type: real 0..1
Default value: 5.0×10^{9}
Description: The minimum mass resolution to use when building merger trees.
Defined in: function:scaledConstructorParameters
File: merger_trees.construct.build.mass_resolution.scaled.F90
Used by:

Name: massStellarRatio
Type: real 0..1
Default value: 0.3
Description: The stellar mass bulge-to-total ratio used to discriminate late-type vs. early-type galaxies.

Defined in: function:galaxySizesSDSSConstructorParameters
File: galacticus.output.analyses.galaxy_sizes_SDSS.F90
Used by:

Name: massThreshold
Type: real 0..1
Default value: 0.0
Description: Threshold mass below which merger tree branches should be pruned.
Defined in: function:pruneByMassConstructorParameters
File: merger_trees.operators.prune_by_mass.F90
Used by:

Name: massThresholdHarrassment
Type: real 1
Default value: 0.0
Description: The host halo mass threshold for harrassment to take effect.
Defined in: function:efstathiou1982TidalConstructorParameters
File: galactic_dynamics.bar_instability.Efstathiou1982Tidal.F90
Used by:

Name: massTransition
Type: real 1
Default value: 1.0
Description: The transition limit for the Chabrier [2001] IMF.
Defined in: function:chabrier2001ConstructorParameters
File: stellar_populations.initial_mass_functions.Chabrier2001.F90
Used by:

Name: massTree
Type: float 1
Default value: spread(1.0d12,1,fixedHalosCount)
Description: Specifies the masses of halos to use when building halos.
Defined in: function:fixedMassConstructorParameters
File: merger_trees.construct.build.masses.fixed_mass.F90
Used by:

Name: massTreeMaximum
Type: real 1
Default value: 1.0×10^{15}
Description: The maximum mass of merger tree base halos to consider when sampled masses from a distribution, in units of $M_\odot$.
Defined in: function:sampledDistributionConstructorParameters
File: merger_trees.construct.build.masses.sampled_distribution.F90
Used by:

Name: massTreeMinimum
Type: real 1
Default value: 1.0×10^{10}
Description: The minimum mass of merger tree base halos to consider when sampled masses from a

distribution, in units of $M_\odot$.
Defined in: function:sampledDistributionConstructorParameters
File: merger_trees.construct.build.masses.sampled_distribution.F90
Used by:

Name: massUpper
Type: real 1
Default value: 125.0
Description: The upper mass limit for the Chabrier [2001] IMF.
Defined in: function:chabrier2001ConstructorParameters
File: stellar_populations.initial_mass_functions.Chabrier2001.F90
Used by:

Name: masses
Type: float 0..1
Description: The masses corresponding to bin centers.
Defined in: function:massFunctionStellarConstructorParameters
File: galacticus.output.analyses.mass_function_stellar.F90
Used by:

Name: massesPerDecade
Type: integer 1
Default value: 10
Description: The number of points per decade of mass at which to tabulate excursion set solutions.
Defined in: function:excursionSetsConstructorParameters
File: tasks.excursion_sets.F90
Used by:

Name: maximinTrialCount
Type: integer 1
Default value: 1000
Description: The number of trial Latin Hypercubes to construct when seeking the maximum minimum separation sample.
Defined in: function:latinHypercubeConstructorParameters
File: posterior_sampling.state.initialize.latin_hypercube.F90
Used by:

Name: mean
Type: real 1
Description: The mean of the normal distribution.
Defined in: function:normalConstructorParameters
File: statistics.distributions.normal.F90
Used by:

Name: meanComment
Type: string 0..1
Description: A descriptive comment for the mean.
Defined in: function:meanFunction1DConstructorParameters
File: galacticus.output.analyses.mean_function_1d.F90

Used by:

Name: `meanCovarianceTarget`
Type: real 0..1
Description: The target function covariance for likelihood calculations.
Defined in: `function:meanFunction1DConstructorParameters`
File: `galacticus.output.analyses.mean_function_1d.F90`
Used by:

Name: `meanLabel`
Type: string 0..1
Description: A label for the mean.
Defined in: `function:meanFunction1DConstructorParameters`
File: `galacticus.output.analyses.mean_function_1d.F90`
Used by:

Name: `meanUnits`
Type: string 0..1
Description: A human-readable description of the units for the mean.
Defined in: `function:meanFunction1DConstructorParameters`
File: `galacticus.output.analyses.mean_function_1d.F90`
Used by:

Name: `meanUnitsInSI`
Type: string 0..1
Description: A units for the mean in the SI system.
Defined in: `function:meanFunction1DConstructorParameters`
File: `galacticus.output.analyses.mean_function_1d.F90`
Used by:

Name: `meanValueTarget`
Type: real 0..1
Description: The target function for likelihood calculations.
Defined in: `function:meanFunction1DConstructorParameters`
File: `galacticus.output.analyses.mean_function_1d.F90`
Used by:

Name: `means`
Type: real 1
Description: The mean of the multivariate normal distribution.
Defined in: `function:multivariateNormalStochasticConstructorParameters`
File: `models.likelihoods.multivariate_normal.stochastic.F90`
Used by:

Name: `median`
Type: real 1
Description: The median of the Cauchy distribution function.
Defined in: `function:cauchyConstructorParameters`
File: `statistics.distributions.Cauchy.F90`

Used by:

Name: `mergeProbability`
Type: real 0..1
Default value: 0.1
Description: The largest probability of branching allowed in a timestep in merger trees built by the Cole et al. [2000] method.
Defined in: `function:cole2000ConstructorParameters`
File: `merger_trees.construct.builder.Cole2000.F90`
Used by:

Name: `mergerTreeEvolutionDump`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to output the evolution of merger trees.
Defined in: `subroutine:Merger_Tree_Dump_Evolution`
File: `merger_trees.dump_evolution.F90`
Used by:

Name: `mergerTreeEvolutionDumpFileName`
Type: text 1
Default value: var_str('mergerTreeEvolution.xml')
Description: Specifies the file to which merger tree evolution should be dumped.
Defined in: `subroutine:Merger_Tree_Dump_Evolution`
File: `merger_trees.dump_evolution.F90`
Used by:

Name: `mergerTreeStructureDump`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to output the structure of merger trees prior to evolution.
Defined in: `subroutine:Merger_Tree_Structure_Dump`
File: `merger_trees.dump_structure.F90`
Used by:

Name: `mergerTreeStructureDumpDirectory`
Type: text 1
Default value: var_str('.')
Description: Specifies the directory to which merger tree structure should be dumped.
Defined in: `subroutine:Merger_Tree_Structure_Dump`
File: `merger_trees.dump_structure.F90`
Used by:

Name: `mergerTreeStructureDumpMassMaximum`
Type: real 1
Default value: huge(1.0d0)
Description: Specifies the minimum root mass for which merger tree structure should be dumped.
Defined in: `subroutine:Merger_Tree_Structure_Dump`
File: `merger_trees.dump_structure.F90`

Used by:

Name: `mergerTreeStructureDumpMassMinimum`
Type: real 1
Default value: 0.0
Description: Specifies the minimum root mass for which merger tree structure should be dumped.
Defined in: subroutine:Merger_Tree_Structure_Dump
File: merger_trees.dump_structure.F90
Used by:

Name: `mergerTreeStructureOutput`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to output the structure of merger trees prior to evolution.
Defined in: subroutine:Merger_Tree_Structure_Output
File: merger_trees.output_structure.F90
Used by:

Name: `mergerTreeStructureOutputDarkMatterProfileScale`
Type: boolean 1
Default value: .false.
Description: Determines whether or not dark matter halo scale radius is included in outputs of merger trees.
Defined in: subroutine:Node_Component_Dark_Matter_Profile_Scale_Initialize
File: objects.nodes.components.dark_matter_profile.scale.F90
Used by:

Name: `mergerTreeStructureOutputDarkMatterProfileShape`
Type: boolean 1
Default value: .false.
Description: Determines whether or not dark matter halo shape parameter is included in outputs of merger trees.
Defined in: subroutine:Node_Component_Dark_Matter_Profile_Scale_Shape_Initialize
File: objects.nodes.components.dark_matter_profile.scale_shape.F90
Used by:

Name: `mergerTreeStructureOutputVirialQuantities`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to output virial quantities (radius and velocity) when outputting the structure of merger trees prior to evolution.
Defined in: subroutine:Merger_Tree_Structure_Output
File: merger_trees.output_structure.F90
Used by:

Name: `metaCollectMemoryUsageData`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not collect and output data on the memory used while processing

trees.
Defined in: subroutine:Meta_Tree_Timing_Initialize
File: galacticus.meta.tree_timing.F90
Used by:

Name: metaCollectTimingData
Type: boolean 1
Default value: .false.
Description: Specifies whether or not collect and output data on the time spent processing trees.
Defined in: subroutine:Meta_Tree_Timing_Initialize
File: galacticus.meta.tree_timing.F90
Used by:

Name: metaProfileTimeStepMaximum
Type: real 1
Default value: 1.0×10^{1}
Description: The largest timestep to use in profiling ODE solver steps.
Defined in: subroutine:Galacticus_Meta_Evolver_Profile
File: galacticus.meta.evolver_profiler.F90
Used by:

Name: metaProfileTimeStepMinimum
Type: real 1
Default value: 1.0×10^{-6}
Description: The smallest timestep to use in profiling ODE solver steps.
Defined in: subroutine:Galacticus_Meta_Evolver_Profile
File: galacticus.meta.evolver_profiler.F90
Used by:

Name: metaProfileTimeStepPointsPerDecade
Type: integer 1
Default value: 3
Description: The number of bins per decade of timestep to use when profiling ODE solver steps.
Defined in: subroutine:Galacticus_Meta_Evolver_Profile
File: galacticus.meta.evolver_profiler.F90
Used by:

Name: metalYield
Type: real 1
Default value: 0.0
Description: The metal yield to use in the instantaneous stellar evolution approximation. (If not specified it will be computed internally.)
Defined in: function:standardConstructorParameters
File: stellar_populations.standard.F90
Used by:

Name: metallicityBoundaries
Type: real 1..
Description: The metallicities corresponding to boundaries between metallicity bins to use when tabu-

lating star formation histories.
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90
Used by:

Name: metallicityMaximum
Type: real 1
Default value: 1.0×10^{1}
Description: The upper limit to the metallicity in the highest metallicity bin when tabulating star formation histories [Solar units].
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90
Used by:

Name: metallicityMinimum
Type: real 1
Default value: 1.0×10^{-4}
Description: The upper limit to the metallicity in the lowest metallicity bin when tabulating star formation histories [Solar units].
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90
Used by:

Name: metallicitySystematicErrorPolynomialCoefficient
Type: float 0..1
Default value: [0.0d0]
Description: The coefficients of the metallicity systematic error polynomial.
Defined in: function:massMetallicityBlanc2017ConstructorParameters
File: galacticus.output.analyses.mass_metallicity_relation.Blanc2017.F90
Used by:

Name: missingHostsAreFatal
Type: boolean 1
Default value: .true.
Description: Specifies whether nodes with missing host nodes should be considered to be fatal—see §5.2.1.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: model
Type: string 1
Default value: var_str('MilkyWayShellTau3.0')
Description: The name of the model from Witt and Gordon [2000] to use in dust attenuation calculations.
Defined in: function:wittGordon2003ConstructorParameters
File: stellar_populations.spectra.dust_attenuation.WittGordon2000.F90
Used by:

Name: `modelParameterName1`
Type: string 0..
Description: Names of parameters to be initialized by initializer number 1.
Defined in: function:switchedConstructorParameters
File: posterior_sampling.state.initialize.switched.F90
Used by:

Name: `modelParameterName2`
Type: string 0..
Description: Names of parameters to be initialized by initializer number 2.
Defined in: function:switchedConstructorParameters
File: posterior_sampling.state.initialize.switched.F90
Used by:

Name: `modelSurfaceBrightness`
Type: boolean 1
Description: If true, model the effects of surface brightness incompleteness on the mass function.
Defined in: function:massFunctionConstructorParameters
File: models.likelihoods.mass_function.F90
Used by:

Name: `modifier1`
Type: string 1
Default value: 0.0
Description: Coefficient of the polynomial modifier applied to the halo mass function when sampling halo masses for tree construction.
Defined in: function:haloMassFunctionConstructorParameters
File: merger_trees.construct.build.masses.distribution.halo_mass_function.F90
Used by:

Name: `modifier2`
Type: string 1
Default value: 0.0
Description: Coefficient of the polynomial modifier applied to the halo mass function when sampling halo masses for tree construction.
Defined in: function:haloMassFunctionConstructorParameters
File: merger_trees.construct.build.masses.distribution.halo_mass_function.F90
Used by:

Name: `molecularFractionFast`
Type: boolean 1
Default value: .false.
Description: Selects whether the fast (but less accurate) fitting formula for molecular hydrogen should be used in the "Krumholz-McKee-Tumlinson" star formation timescale calculation.
Defined in: function:krumholz2009ConstructorParameters
File: star_formation.rate_surface_density.disks.Krumholz2009.F90
Used by:

Name: `monotonicInterpolation`

Type: real 1
Default value: .false.
Description: If true use a monotonic cubic spline interpolator to interpolate in the $\sigma(M)$ table. Otherwise use a standard cubic spline interpoltor. Use of the monotionic interpolator can be helpful is $\sigma(M)$ must be strictly monotonic but because a very weak function of M at low masses.
Defined in: `function:filteredPowerConstructorParameters`
File: `structure_formation.cosmological_mass_variance.filtered_power_spectrum.F90`
Used by:

Name: `mu`
Type: real 1
Description: The parameter γ of the Voight function.
Defined in: `function:voightConstructorParameters`
File: `statistics.distributions.Voight.F90`
Used by:

Name: `muRatioHigh`
Type: real 1
Default value: [+1.100d0,+1.100d0,+1.084d0]
Description: Values of the μ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.05–0.5 mass ratio.
Defined in: `function:jiang2014ConstructorParameters`
File: `satellites.merging.virial_orbits.Jiang2014.F90`
Used by:

Name: `muRatioIntermediate`
Type: real 1
Default value: [+1.181d0,+1.201d0,+1.236d0]
Description: Values of the μ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.005–0.05 mass ratio.
Defined in: `function:jiang2014ConstructorParameters`
File: `satellites.merging.virial_orbits.Jiang2014.F90`
Used by:

Name: `muRatioLow`
Type: real 1
Default value: [+1.220d0,+1.231d0,+1.254d0]
Description: Values of the μ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.0001–0.005 mass ratio.
Defined in: `function:jiang2014ConstructorParameters`
File: `satellites.merging.virial_orbits.Jiang2014.F90`
Used by:

Name: `multiplier`
Type: float 0..1
Description: Multiplying factor.
Defined in: `function:multiplyConstructorParameters`
File: `galacticus.output.analyses.property_operator.multiply.F90`
Used by:

Name: nBodyFileName
Type: string 1
Description: The name of the file containing the N-body data.
Defined in: function:nbodyAnalyzeConstructorParameters
File: tasks.nBody_analyze.F90
Used by:

Name: name
Type: string 1
Description: A human-readable name for the units of velocity.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: names
Type: string 1
Default value: [var_str('default')]
Description: The names assigned to stellar spectra postprocessors.
Defined in: function:lookupConstructorParameters
File: stellar_populations.spectra.postprocess.builder.lookup.F90
Used by:

Name: nbodyFileNamePrevious
Type: string 1
Description: The name of the file containing the N-body data.
Defined in: function:nbodyAnalyzeConstructorParameters
File: tasks.nBody_analyze.F90
Used by:

Name: negativeBinomialScatterFractional
Type: float 0..1
Default value: 0.18 [Boylan-Kolchin et al., 2010]
Description: The fractional scatter (relative to the Poisson scatter) in the negative binomial distribution used in likelihood calculations.
Defined in: function:localGroupMassFunctionConstructorParameters
File: galacticus.output.analyses.Local_Group_mass_functions.F90
Used by:

Name: neighborCount
Type: string 1
Description: The number of nearest neighbors to use when estimating the posterior likelihood.
Defined in: function:posteriorAsPriorConstructorParameters
File: models.likelihoods.posterior_as_prior.F90
Used by:

Name: neutrinoMassSummed
Type: real 0..1
Default value: 0.0

Description: The summed mass (in electron volts) of all neutrino species.
Defined in: function:eisensteinHu1999ConstructorParameters
File: structure_formation.transfer_function.Eisenstein_Hu.F90
Used by:

Name: neutrinoNumberEffective
Type: real 0..1
Default value: 3.046 [Mangano et al., 2005]
Description: The effective number of neutrino species.
Defined in: function:eisensteinHu1999ConstructorParameters
File: structure_formation.transfer_function.Eisenstein_Hu.F90
Used by:

Name: nodeComponentBasicExtendedSphericalCollapseEnergyFixedAt
Type: string 1
Default value: var_str('turnaround')
Description: Selects the epoch at which the energy of a spherical top hat perturbation in a dark energy cosmology should be "fixed" for the purposes of computing virial density contrasts. (See the discussion in Percival 2005; §8.).
Defined in: subroutine:Node_Component_Basic_Extended_Bindings
File: objects.nodes.components.basic.extended.F90
Used by:

Name: nodeComponentBasicExtendedSphericalCollapseType
Type: string 1
Default value: var_str('matterLambda')
Description: The type of spherical collapse model to assume in the extended basic node component class.
Defined in: subroutine:Node_Component_Basic_Extended_Bindings
File: objects.nodes.components.basic.extended.F90
Used by:

Name: nodeFormationMassFraction
Type: double 1
Default value: 0.5
Description: The mass fraction in the main branch progenitor used to define the formation time of each halo.
Defined in: subroutine:Node_Component_Merging_Statistics_Standard_Initialize
File: objects.nodes.components.merging_statistics.standard.F90
Used by:

Name: nodeMajorMergerFraction
Type: double 1
Default value: 0.25
Description: The mass ratio (M_2/M_1 where $M_2 < M_1$) of merging halos above which the merger should be considered to be "major".
Defined in: subroutine:Node_Component_Merging_Statistics_Standard_Initialize
File: objects.nodes.components.merging_statistics.standard.F90
Used by:

Name: nodePromotionIndexShift
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the index of a node should be shifted to its parent node prior to promotion.
Defined in: subroutine:Node_Promotion_Index_Shift
File: events.node_promotion.index_shift.F90
Used by:

Name: nodeRecentMajorMergerFromInfall
Type: double 1
Default value: .false.
Description: Specifies whether "recent" for satellite galaxies is measured from the current time, or from the time at which they were last isolated.
Defined in: subroutine:Node_Component_Merging_Statistics_Recent_Initialize
File: objects.nodes.components.merging_statistics.recent.F90
Used by:

Name: nodeRecentMajorMergerInterval
Type: double 1
Default value: 2.0
Description: The time interval used to define "recent" mergers in the `recent` merging statistics component. This parameter is in units of Gyr if `[nodeRecentMajorMergerIntervalType]`=`absolute`, or in units of the halo dynamical time if `[nodeRecentMajorMergerIntervalType]`=`dynmical`.
Defined in: subroutine:Node_Component_Merging_Statistics_Recent_Initialize
File: objects.nodes.components.merging_statistics.recent.F90
Used by:

Name: nodeRecentMajorMergerIntervalType
Type: double 1
Default value: var_str('dynamical')
Description: Specifies the units for the `[nodeRecentMajorMergerInterval]` parameter. If set to `absolute` then `[nodeRecentMajorMergerInterval]` is given in Gyr, while if set to `dynamical` `[nodeRecentMajorMergerInte` is given in units of the halo dynamical time.
Defined in: subroutine:Node_Component_Merging_Statistics_Recent_Initialize
File: objects.nodes.components.merging_statistics.recent.F90
Used by:

Name: nonAnalyticSolver
Type: string 1
Default value: var_str('fallThrough')
Description: Selects how solutions are computed when no analytic solution is available. If set to "`fallThrough`" then the solution ignoring heating is used, while if set to "`numerical`" then numerical solvers are used to find solutions.
Defined in: function:truncatedExponentialConstructorParameters
File: dark_matter_profiles_DMO.truncated.exponential.F90
Used by:

Name: `nonCosmological`
Type: boolean 0..1
Default value: .false.
Description: If true, a non-cosmological snapshot file will be created.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: `normalization`
Type: string 1
Default value: var_str('natural')
Description: The parameter a in the relation $k_\mathrm{s} = a/r_\mathrm{s}$, where k_s is the cut-off wavenumber for the sharp k-space window function and r_s is the radius of a sphere (in real-space) enclosing the requested smoothing mass. Alternatively, a value of `natural` will be supplied in which case the normalization is chosen such that, in real-space, $W(r=0)=1$. This results in a contained mass of $M = 6\pi^2\bar{\rho}k_\mathrm{s}^{-3}$.
Defined in: function:topHatSharpKHybridConstructorParameters
File: structure_formation.power_spectrum.variance.window_function.top_hat_kspace_sharp_-hybrid.F90
Used by:

Name: `nu`
Type: real 1
Default value: 1.1 [Barkana et al., 2001, for the transfer function at $z = z_\mathrm{eq}$]
Description: The parameter ϵ appearing in the warm dark matter transfer function [Barkana et al., 2001].
Defined in: function:bode2001ConstructorParameters
File: structure_formation.transfer_function.Bode2001.F90
Used by:

Name: `odeAlgorithm`
Type: real 1
Default value: var_str('rungeKuttaCashKarp')
Description: The algorithm to use in the ODE solver.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: `odeAlgorithmNonJacobian`
Type: real 1
Default value: var_str('rungeKuttaCashKarp')
Description: The algorithm to use in the ODE solver.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: `odeJacobianStepSizeRelative`
Type: real 1
Default value: 0.01
Description: The relative step size to use when perturbing properties for purposes of computing a finite

difference approximation to the ODE system Jacobian.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: odeLatentIntegratorIntervalsMaximum
Type: integer 1
Default value: 1000
Description: The maxium number of intervals allowed in the integrator for latent variables.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: odeLatentIntegratorOrder
Type: integer 1
Default value: 15
Description: The order of the integrator for latent variables.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: odeLatentIntegratorType
Type: string 1
Default value: var_str('trapezoidal')
Description: The type of integrator to use for latent variables.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: odeToleranceAbsolute
Type: real 1
Default value: 0.01
Description: The absolute tolerance used in solving differential equations for node evolution.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: odeToleranceRelative
Type: real 1
Default value: 1.0×10^{-2}
Description: The relative tolerance used in solving differential equations for node evolution.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: offset
Type: integer 1
Description: The offset of the stride to take over forests.
Defined in: function:strideConstructorParameters

File: tasks.evolve_forests.work_share.stride.F90
Used by:

Name: omega
Type: real 1
Default value: 0.77 (Gustafsson et al. 2006; from their Fig. 9, strong feedback case)
Description: The parameter ω appearing in the Gnedin et al. [2004] adiabatic contraction algorithm.
Defined in: function:adiabaticGnedin2004ConstructorParameters
File: dark_matter_profiles.adiabatic_Gnedin2004.F90
Used by:

Name: opacityExponent
Type: real 1
Default value: 0.7
Description: The exponent of wavelength appearing in the opacity.
Defined in: function:charlotFall2000ConstructorParameters
File: stellar_populations.spectra.dust_attenuation.CharlotFall2000.F90
Used by:

Name: opticalDepthBirthClouds
Type: real 1
Default value: 1.0
Description: The effective optical depth of birth clouds.
Defined in: function:charlotFall2000ConstructorParameters
File: stellar_populations.spectra.dust_attenuation.CharlotFall2000.F90
Used by:

Name: opticalDepthISM
Type: real 1
Default value: 0.5
Description: The effective optical depth of the ISM.
Defined in: function:charlotFall2000ConstructorParameters
File: stellar_populations.spectra.dust_attenuation.CharlotFall2000.F90
Used by:

Name: opticalDepthReionization
Type: real 1
Description: The optical depth to electron scattering below which baryonic accretion is suppressed.
Defined in: function:simpleConstructorParameters
File: accretion.halo.simple.F90
Used by:

Name: origin
Type: float 1
Default value: [randomSequence%uniformSample(),randomSequence%uniformSample(),randomSequence%uniformSample(
Uniformly random distribution within the box.
Description: The vector (in units of the box length) giving the origin of the coordinate system to use in mock catalog construction.
Defined in: function:catalogProjectedCorrelationFunctionConstructorParameters

File: tasks.catalog_projected_correlation_function.F90
Used by:

Name: outerRadius
Type: real 1
Description: The outer radius of a β-model mass distribution.
Defined in: function:betaProfileConstructorParameters
File: mass_distributions.spherical.beta_profile.F90
Used by:

Name: outlierCountMaximum
Type: integer 1
Default value: 0
Description: The maximum number of outlier states allowed.
Defined in: function:gelmanRubinConstructorParameters
File: posterior_sampling.convergence.Gelman-Rubin.F90
Used by:

Name: outlierLogLikelihoodOffset
Type: real 1
Default value: 0.0
Description: The log-likelihood offset at which to declare a state an outlier.
Defined in: function:gelmanRubinConstructorParameters
File: posterior_sampling.convergence.Gelman-Rubin.F90
Used by:

Name: outlierSignificance
Type: real 1
Default value: 0.05
Description: The significance at which to declare a state an outlier.
Defined in: function:gelmanRubinConstructorParameters
File: posterior_sampling.convergence.Gelman-Rubin.F90
Used by:

Name: outputFileName
Type: string 1
Description: The name of the file to which to write merger tree data.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: outputFormat
Type: string 1
Description: The format to use for merger tree output.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: outputGroup

Type: integer 1
Default value: var_str('.')
Description: The HDF5 output group within which to write power spectrum data.
Defined in: function:powerSpectraConstructorParameters
File: tasks.power_spectrum.F90
Used by:

Name: outputGroupName
Type: string 1
Description: The name of the file to which the computed conditional mass function should be output.
Defined in: function:conditionalMassFunctionConstructorParameters
File: tasks.conditional_mass_function.F90
Used by:

Name: outputHaloModelData
Type: boolean 1
Default value: .false.
Description: Specifies whether or not halo model data (bias, power spectra, etc.) should be included in the output.
Defined in: subroutine:Galacticus_Output_Halo_Model_Initialize
File: galacticus.output.merger_tree.halo_model.F90
Used by:

Name: outputReferences
Type: boolean 1
Default value: .false.
Description: Specifies whether or not references to individual merger tree datasets should be output.
Defined in: function:standardConstructorParameters
File: merger_trees.outputter.standard.F90
Used by:

Name: outputSatelliteMergers
Type: boolean 1
Default value: .false.
Description: Specifies whether satellite merger information should be output.
Defined in: subroutine:Satellite_Merging_Output
File: satellites.merging.output.F90
Used by:

Name: outputSatelliteMergersMainBranchOnly
Type: boolean 1
Default value: .true.
Description: Specifies whether satellite merger information should be output only for the main branch host halo.
Defined in: subroutine:Satellite_Merging_Output
File: satellites.merging.output.F90
Used by:

Name: outputTimeSnapTolerance

Type: real 1
Default value: 0.0
Description: The relative tolerance required to "snap" a node time to the closest output time.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: outputWeight
Type: float 0..1
Description: The weight to assign to each bin at each output.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: outputsGroupName
Type: string 1
Default value: var_str('Outputs')
Description: The name of the HDF5 group to which outputs will be written.
Defined in: function:standardConstructorParameters
File: merger_trees.outputter.standard.F90
Used by:

Name: p
Type: real 0..1
Default value: 0.3
Description: The parameter p in the Sheth et al. [2001] halo mass function fit.
Defined in: function:shethTormenConstructorParameters
File: structure_formation.halo_mass_function.Sheth-Tormen.F90
Used by:

Name: parentMassCount
Type: integer 1
Default value: 10
Description: The number of bins in parent mass when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: parentMassMaximum
Type: real 1
Default value: 1.0×10^{15}
Description: The maximum parent halo mass to bin when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: parentMassMinimum
Type: real 1
Default value: 1.0×10^{10}

Description: The minimum parent halo mass to bin when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: parentRedshifts
Type: real 1..
Default value: [0.0d0]
Description: The set of parent halo redshifts to use when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: particleCountMinimum
Type: real 1
Description: The minimum particle count used in N-body halos.
Defined in: function:spinDistributionConstructorParameters
File: models.likelihoods.spin_distribution.F90
Used by:

Name: particleType
Type: integer 0..1
Description: The particle type to read from the Gadget HDF5 file.
Defined in: function:gadgetHDF5ConstructorParameters
File: nBody.import.GadgetHDF5.F90
Used by:

Name: particlesFileName
Type: string 1
Description: The name of the file from which to read particle data.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: path
Type: text 1
Default value: var_str('.')
Description: Specifies the directory to which merger tree structure should be dumped.
Defined in: function:dumpToGraphVizConstructorParameters
File: merger_trees.operators.dump_to_GraphViz.F90
Used by:

Name: performChecks
Type: logical 0..
Default value: .false.
Description: If true, perform checks of the augmentation process.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: `periodic`
Type: real 0..1
Default value: .false.
Description: If true, periodic boundary conditions will be used.
Defined in: `function:environmentalOverdensityConstructorParameters`
File: `nBody.operator.environmental_overdensity.F90`
Used by:

Name: `phi0`
Type: real 1
Default value: 6.58
Description: The parameter ϕ_0 appearing in the halo concentration algorithm of Diemer and Kravtsov [2014].
Defined in: `function:diemerKravtsov2014ConstructorParameters`
File: `dark_matter_profiles.structure.concentration.Diemer-Kravtsov2014.F90`
Used by:

Name: `phi1`
Type: real 1
Default value: 1.37
Description: The parameter ϕ_1 appearing in the halo concentration algorithm of Diemer and Kravtsov [2014].
Defined in: `function:diemerKravtsov2014ConstructorParameters`
File: `dark_matter_profiles.structure.concentration.Diemer-Kravtsov2014.F90`
Used by:

Name: `pointsPerDecade`
Type: integer 1
Default value: 10
Description: The number of points per decade of wavenumber at which to tabulate power spectra.
Defined in: `function:powerSpectraConstructorParameters`
File: `tasks.power_spectrum.F90`
Used by:

Name: `polynomialOrder`
Type: integer 1
Default value: 2
Description: The order of the polynomial to fit to the likelihood surface.
Defined in: `function:gaussianRegressionConstructorParameters`
File: `models.likelihoods.gaussian_regression.F90`
Used by:

Name: `positionOffset`
Type: boolean 0..1
Default value: .false.
Description: If true, offset particle representations to the positions/velocities of nodes.
Defined in: `function:particulateConstructorParameters`
File: `merger_trees.operators.particulate.F90`

Used by:

Name: `positionsArePeriodic`
Type: boolean 1
Description: Specifies whether or not positions are periodic.
Defined in: `function:mergerTreeFileBuilderConstructorParameters`
File: `tasks.merger_tree_file_builder.F90`
Used by:

Name: `positionsPresetSatelliteToHost`
Type: bool 1
Default value: .false.
Description: If true, the position of satellite halos will be adjusted to match that of their host halo.
Defined in: `subroutine:Node_Component_Position_Preset_Initialize`
File: `objects.nodes.components.position.preset.F90`
Used by:

Name: `postprocessChain`
Type: string 0..1
Description: The postprocessing chain to use.
Defined in: `function:luminosityStellarConstructorParameters`
File: `nodes.property_extractor.luminosity_stellar.F90`
Used by:

Name: `preReionizationTemperature`
Type: real 1
Default value: 10.0
Description: The pre-reionization temperature (in units of Kelvin) in the simple IGM state model.
Defined in: `function:simpleIGMConstructorParameters`
File: `intergalactic_medium.state.simple.F90`
Used by:

Name: `precisionHypergeometric`
Type: real 1
Default value: 1.0×10^{-6}
Description: The fractional precision required in evaluates of hypergeometric functions in the modified Press-Schechter tree branching calculations.
Defined in: `function:parkinsonColeHellyConstructorParameters`
File: `merger_trees.branching_probability.Parkinson_Cole_Helly.F90`
Used by:

Name: `presentDayTemperature`
Type: real 1
Default value: 1.0×10^{3}
Description: The present day temperature (in units of Kelvin) in the instantReionization IGM state model.
Defined in: `function:instantReionizationIGMConstructorParameters`
File: `intergalactic_medium.state.instant_reionization.F90`
Used by:

Name: `preservePrimaryProgenitor`
Type: boolean 0..1
Default value: .true.
Description: If true, primary progenitor status is preserved even if the primary progenitor is pruned from the tree.
Defined in: function:pruneByMassConstructorParameters
File: merger_trees.operators.prune_by_mass.F90
Used by:

Name: `presetMergerNodes`
Type: boolean 1
Default value: .true.
Description: Specifies whether the target nodes for mergers should be preset (i.e. determined from descendent nodes). If they are not, merging will be with each satellite's host node.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: `presetMergerTimes`
Type: boolean 1
Default value: .true.
Description: Specifies whether merging times for subhalos should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: `presetNamedIntegers`
Type: string 1..
Description: Names of integer datasets to be additionally read and stored in the nodes of the merger tree when using the `[mergerTreeConstructMethod]=read` tree construction method.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: `presetNamedReals`
Type: string 1..
Description: Names of real datasets to be additionally read and stored in the nodes of the merger tree when using the `[mergerTreeConstructMethod]=read` tree construction method.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: `presetOrbits`
Type: boolean 1
Default value: .true.
Description: Specifies whether node orbits should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters

File: merger_trees.construct.read.F90
Used by:

Name: presetOrbitsAssertAllSet
Type: boolean 1
Default value: .true.
Description: Asserts that all virial orbits must be preset. If any can not be set, Galacticus will stop.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetOrbitsBoundOnly
Type: boolean 1
Default value: .true.
Description: Specifies whether only bound node orbits should be set.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetOrbitsSetAll
Type: boolean 1
Default value: .true.
Description: Forces all orbits to be set. If the computed orbit does not cross the virial radius, then select one at random instead.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetPositions
Type: boolean 1
Default value: .true.
Description: Specifies whether node positions should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetScaleRadii
Type: boolean 1
Default value: .true.
Description: Specifies whether node scale radii should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetScaleRadiiConcentrationMaximum
Type: boolean 1
Default value: 60.0
Description: The largest concentration ($c = r_{\rm vir}/r_{\rm s}$) allowed when setting scale radii, $r_{\rm s}$.
Defined in: function:readConstructorParameters

File: merger_trees.construct.read.F90
Used by:

Name: presetScaleRadiiConcentrationMinimum
Type: boolean 1
Default value: 3.0
Description: The lowest concentration ($c = r_{\rm vir}/r_{\rm s}$) allowed when setting scale radii, $r_{\rm s}$.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetScaleRadiiMinimumMass
Type: boolean 1
Default value: 0.0
Description: The minimum halo mass for which scale radii should be preset (if [presetScaleRadii]=true).
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetSpins
Type: boolean 1
Default value: .true.
Description: Specifies whether node spins should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetSpins3D
Type: boolean 1
Default value: .false.
Description: Specifies whether node 3-D spin vectors should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetSubhaloIndices
Type: boolean 1
Default value: .true.
Description: Specifies whether subhalo indices should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: presetSubhaloMasses
Type: boolean 1
Default value: .true.
Description: Specifies whether subhalo mass should be preset when reading merger trees from a file.
Defined in: function:readConstructorParameters

File: merger_trees.construct.read.F90
Used by:

Name: presetUnphysicalSpins
Type: boolean 1
Default value: .false.
Description: When reading merger trees from file and presetting halo spins, detect unphysical (<=0) spins and preset them using the selected halo spin method.
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: pressureCharacteristic
Type: real 1
Default value: 4.54 [Blitz and Rosolowsky, 2006]
Description: The characteristic pressure (given as P_0/k_B in units of K cm^{-3}) in the scaling relation of molecular hydrogen fraction with disk pressure in the "Blitz-Rosolowsky2006" star formation timescale calculation.
Defined in: function:blitz2006ConstructorParameters
File: star_formation.rate_surface_density.disks.Blitz2006.F90
Used by:

Name: pressureExponent
Type: real 1
Default value: 0.92 [Blitz and Rosolowsky, 2006]
Description: The exponent in the scaling relation of molecular hydrogen fraction with disk pressure in the "Blitz-Rosolowsky2006" star formation timescale calculation.
Defined in: function:blitz2006ConstructorParameters
File: star_formation.rate_surface_density.disks.Blitz2006.F90
Used by:

Name: primaryProgenitorDepth
Type: integer 1
Default value: 2
Description: The depth in progenitor ranking for which to store ranked progenitor mass functions. For example, a value of 2 means store mass functions for the most massive, and second most massive progenitor.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: probabilitySuccess
Type: real 1
Description: The probability of success for a single trial.
Defined in: function:negativeBinomialConstructorParameters
File: statistics.distributions.discrete.negative_binomial.F90
Used by:

Name: processDescending

Type: boolean 1
Default value: .true.
Description: If true, causes merger trees to be processed in order of decreasing mass.
Defined in: function:buildConstructorParameters
File: merger_trees.construct.build.F90
Used by:

Name: profileOdeEvolver
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to profile the ODE evolver.
Defined in: function:standardConstructorParameters
File: merger_trees.node_evolver.standard.F90
Used by:

Name: progenitorRedshifts
Type: real 1..
Default value: [1.0d0]
Description: The set of progenitor halo redshifts to use when constructing conditional halo mass functions.
Defined in: function:conditionalMFConstructorParameters
File: merger_trees.operators.conditional_mass_function.F90
Used by:

Name: propertyComment
Type: string 0..1
Description: A descriptive comment for the property variable.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: propertyLabel
Type: string 0..1
Description: A label for the property variable.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: propertyUnits
Type: string 0..1
Description: A human-readable description of the units for the property.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: propertyUnitsInSI
Type: string 0..1
Description: A units for the property in the SI system.
Defined in: function:volumeFunction1DConstructorParameters

File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: proposalSize
Type: real 1
Description: The proposal size, γ.
Defined in: function:fixedConstructorParameters
File: posterior_sampling.differential_proposal_size.fixed.F90
Used by:

Name: q
Type: real 0..1
Default value: 1.795 [Comparat et al., 2017]
Description: The parameter $\bar{q}$ in the Bhattacharya et al. [2011] halo mass function fit.
Defined in: function:bhattacharya2011ConstructorParameters
File: structure_formation.halo_mass_function.Bhattacharya2011.F90
Used by:

Name: radii
Type: real 1..*
Description: A list of radii at which to output the mass profile.
Defined in: function:massProfileConstructorParameters
File: nodes.property_extractor.mass_profile.F90
Used by:

Name: radiiRatio
Type: real 1
Default value: 1.0
Description: The parameter β in the relation $r_\mathrm{s} = \beta r_\mathrm{th}$ between k-space sharp and top-hat window function radii in the hybrid window function used for computing the variance in the power spectrum.
Defined in: function:topHatSharpKHybridConstructorParameters
File: structure_formation.power_spectrum.variance.window_function.top_hat_kspace_sharp_-hybrid.F90
Used by:

Name: radius
Type: float 0..
Description: Radii at which the rotation curve should be computed.
Defined in: function:rotationCurveConstructorParameters
File: nBody.operator.rotation_curve.F90
Used by:

Name: radiusEnvironment
Type: real 0..1
Default value: 7.0
Description: The radius of the sphere used to determine the variance in the environmental density.
Defined in: function:normalConstructorParameters
File: structure_formation.halo_environment.normal.F90
Used by:

Name: `radiusFixed`
Type: string 1
Default value: var_str('virial')
Description: The radius to use in the "fixed" galactic structure radius solver algorithm. Allowed options are "virial" and "turnaround".
Defined in: `function:fixedConstructorParameters`
File: `galactic_structure.radius_solver.fixed.F90`
Used by:

Name: `radiusFractionalDecay`
Type: float 1
Default value: 1.0
Description: The truncation scale (in units of the virial radius).
Defined in: `function:truncatedExponentialConstructorParameters`
File: `dark_matter_profiles_DMO.truncated.exponential.F90`
Used by:

Name: `radiusFractionalTruncateMaximum`
Type: float 1
Default value: 4.0
Description: The maximum radius (in units of the virial radius) to finish truncating the density profile.
Defined in: `function:truncatedConstructorParameters`
File: `dark_matter_profiles_DMO.truncated.F90`
Used by:

Name: `radiusFractionalTruncateMinimum`
Type: float 1
Default value: 2.0
Description: The minimum radius (in units of the virial radius) to begin truncating the density profile.
Defined in: `function:truncatedConstructorParameters`
File: `dark_matter_profiles_DMO.truncated.F90`
Used by:

Name: `radiusHalfMass`
Type: real 1
Default value: 1.0
Description: The half mass radius of the Sérsic profile.
Defined in: `function:sersicConstructorParameters`
File: `mass_distributions.spherical.Sersic.F90`
Used by:

Name: `radiusInner`
Type: float 0..
Description: Inner radii of spherical shells within which the velocity dispersion should be computed.
Defined in: `function:velocityDispersionConstructorParameters`
File: `nBody.operator.velocity_dispersion.F90`
Used by:

Name: radiusOuter
Type: float 0..
Description: Outer radii of spherical shells within which the velocity dispersion should be computed.
Defined in: function:velocityDispersionConstructorParameters
File: nBody.operator.velocity_dispersion.F90
Used by:

Name: radiusShock
Type: real 1
Default value: 1.0
Description: The shock radius, s, (in units of the halo virial radius) in the Patej and Loeb [2015] hot halo gas mass distribution model.
Defined in: function:patejLoeb2015ConstructorParameters
File: hot_halo.mass_distribution.PatejLoeb2015.F90
Used by:

Name: radiusSpecifiers
Type: real 1..*
Description: A list of radius specifiers at which to output the velocity dispersion.
Defined in: function:velocityDispersionConstructorParameters
File: nodes.property_extractor.velocity_dispersion.F90
Used by:

Name: radiusSphere
Type: real 0..1
Description: The radius of the sphere within which to measure environmental overdensity.
Defined in: function:environmentalOverdensityConstructorParameters
File: nBody.operator.environmental_overdensity.F90
Used by:

Name: radiusTree
Type: float 1
Default value: spread(-1.0d0,1,fixedHalosCount)
Description: Specifies the radii within which halo masses are specified when building halos.
Defined in: function:fixedMassConstructorParameters
File: merger_trees.construct.build.masses.fixed_mass.F90
Used by:

Name: radiusTruncateOverRadiusVirial
Type: real 0..1
Description: Radius (in units of the virial radius) at which to truncate halo profiles.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: randomErrorMaximum
Type: float 0..1
Default value: 0.07
Description: The minimum random error for stellar masses.

Defined in: function:morphologicalFractionGAMAMoffett2016ConstructorParameters
File: galacticus.output.analyses.morphological_fraction.GAMA_Moffett2016.F90
Used by:

Name: randomErrorMinimum
Type: float 0..1
Default value: 0.07
Description: The minimum random error for stellar masses.
Defined in: function:morphologicalFractionGAMAMoffett2016ConstructorParameters
File: galacticus.output.analyses.morphological_fraction.GAMA_Moffett2016.F90
Used by:

Name: randomErrorPolynomialCoefficient
Type: float 0..1
Default value: [0.0d0]
Description: The coefficients of the random error polynomial.
Defined in: function:morphologicalFractionGAMAMoffett2016ConstructorParameters
File: galacticus.output.analyses.morphological_fraction.GAMA_Moffett2016.F90
Used by:

Name: randomSampleCount
Type: float 1
Default value: var_str('*10')
Description: The number of random points to use when constructing random catalogs. Can be either a fixed number or, if prefixed with "*", a multiplicative factor.
Defined in: function:catalogProjectedCorrelationFunctionConstructorParameters
File: tasks.catalog_projected_correlation_function.F90
Used by:

Name: randomSeed
Type: integer 1
Default value: 219
Description: A seed value for the random number generator.
Defined in: subroutine:pseudoRandomInitialize
File: numerical.random.F90
Used by:

Name: randomSpinResetMassFactor
Type: double 1
Default value: 2.0
Description: The factor by which a node must increase in mass before its spin parameter is reset.
Defined in: subroutine:Node_Component_Spin_Random_Initialize
File: objects.nodes.components.spin.random.F90
Used by:

Name: randomize
Type: boolean 1
Default value: .false.
Description: If true, randomize models (i.e. change the random seed).

Defined in: function:galaxyPopulationConstructorParameters
File: models.likelihoods.galaxy_population.F90
Used by:

Name: rangeLower
Type: float 0..1
Description: Lower integration limit for the normal distribution weight operator.
Defined in: function:normalConstructorParameters
File: galacticus.output.analyses.property_operator.normal.F90
Used by:

Name: rangeUpper
Type: float 0..1
Description: Upper integration limit for the normal distribution weight operator.
Defined in: function:normalConstructorParameters
File: galacticus.output.analyses.property_operator.normal.F90
Used by:

Name: rate
Type: real 1
Description: The rate parameter of the negative exponential distribution function.
Defined in: function:negativeExponentialConstructorParameters
File: statistics.distributions.negative_exponential.F90
Used by:

Name: rateAdjust
Type: real 1
Default value: 0.3
Description: The dimensionless multiplier for the rate at which the halo gas content adjusts to changes in the filtering mass.
Defined in: function:naozBarkana2007ConstructorParameters
File: accretion.halo.Naoz_Barkana_2007.F90
Used by:

Name: rateFractionalMaximum
Type: string 1
Default value: 10.0
Description: The maximum fractional mass loss rate per dynamical time in the simple model of mass loss from spheroids due to tidal stripping.
Defined in: function:simpleConstructorParameters
File: tidal_stripping.mass_loss_rate.spheroids.simple.F90
Used by:

Name: ratioEarlyType
Type: real 0..1
Default value: 0.5
Description: The minimum spheroid-to-total ratio for a galaxy to be classified as "early-type" when constructing the Galaxy and Mass Assembly (GAMA) early-type fraction function.
Defined in: function:morphologicalFractionGAMAMoffett2016ConstructorParameters

File: galacticus.output.analyses.morphological_fraction.GAMA_Moffett2016.F90
Used by:

Name: ratioEarlyTypeError
Type: real 0..1
Default value: 0.3
Description: The error in spheroid fraction to be used when constructing the GAMA early-type fraction function.
Defined in: function:morphologicalFractionGAMAMoffett2016ConstructorParameters
File: galacticus.output.analyses.morphological_fraction.GAMA_Moffett2016.F90
Used by:

Name: ratioMassBurst
Type: real 1
Default value: 0.05
Description: The mass ratio above which mergers are considered to trigger a burst.
Defined in: function:baugh2005ConstructorParameters
File: satellites.merging.mass_movements.Baugh2005.F90
Used by:

Name: realizationCount
Type: integer 1
Description: The number of realizations of the stochastic likelihood to compute at unit temperature.
Defined in: function:multivariateNormalStochasticConstructorParameters
File: models.likelihoods.multivariate_normal.stochastic.F90
Used by:

Name: realizationCountMinimum
Type: integer 1
Description: The minimum number of realizations of the stochastic likelihood to compute at higher temperatures.
Defined in: function:multivariateNormalStochasticConstructorParameters
File: models.likelihoods.multivariate_normal.stochastic.F90
Used by:

Name: recycledFraction
Type: real 1
Default value: 0.0
Description: The recycled fraction to use in the instantaneous stellar evolution approximation. (If not specified it will be computed internally.)
Defined in: function:standardConstructorParameters
File: stellar_populations.standard.F90
Used by:

Name: redshift
Type: real 1
Default value: 0.0
Description: The redshift at which the transfer function is defined.
Defined in: function:identityConstructorParameters

File: structure_formation.transfer_function.identity.F90
Used by:

Name: redshiftBand
Type: float 0..1
Description: The redshift of the band (if not the output redshift).
Defined in: function:lmnstyStllrChrltFll2000ConstructorParameters
File: nodes.property_extractor.luminosity_stellar.dust.CharlotFall2000.F90
Used by:

Name: redshiftBase
Type: real 1
Default value: 0.0
Description: The redshift at which to plant the base node when building the smoothly accreting merger tree.
Defined in: function:smoothAccretionConstructorParameters
File: merger_trees.construct.smooth_accretion.F90
Used by:

Name: redshiftBin
Type: integer 1
Description: The redshift bin (0, 1, 2, 3, 4, 5, 6, or 7) of the Tomczak et al. [2014] mass function to use.
Defined in: function:tomczak2014ZFOURGEConstructorParameters
File: geometry.surveys.Tomczak-2014-ZFOURGE.F90
Used by:

Name: redshiftCutOff
Type: real 1
Default value: 0.0
Description: The redshift below which cooling is suppressed in the "cut-off" cooling rate modifier method.
Defined in: function:cutOffConstructorParameters
File: cooling.cooling_rate.cut_off.F90
Used by:

Name: redshiftEarliest
Type: real 1
Default value: 0.0
Description: Redshift at which to truncate merger tree branches.
Defined in: function:pruneByTimeConstructorParameters
File: merger_trees.operators.prune_by_time.F90
Used by:

Name: redshiftExponent
Type: real 1
Default value: -1.5d0
Description: The exponent of redshift in the velocity maximum scaling model for outflow reincorporation.
Defined in: function:velocityMaximumScalingConstructorParameters

File: hot_halo.outflow_reincorporation.velocity_maximum_scaling.F90
Used by:

Name: redshiftInterval
Type: integer 0..1
Description: The redshift interval (1, 2, or 3) to use.
Defined in: function:stellarVsHaloMassRelationLeauthaud2012ConstructorParameters
File: galacticus.output.analyses.stellar_vs_halo_mass_relation.COSMOS_Leauthaud2012.F90
Used by:

Name: redshiftMaximum
Type: real 1
Default value: 10.0
Description: The maximum redshift at which to tabulate excursion set solutions.
Defined in: function:excursionSetsConstructorParameters
File: tasks.excursion_sets.F90
Used by:

Name: redshiftMinimum
Type: real 1
Default value: 0.0
Description: The minimum redshift at which to tabulate excursion set solutions.
Defined in: function:excursionSetsConstructorParameters
File: tasks.excursion_sets.F90
Used by:

Name: redshiftReionization
Type: real 1
Default value: 9.97 (Hinshaw et al. 2012; CMB+H_0+BAO)
Description: The redshift below which baryonic accretion is suppressed.
Defined in: function:simpleConstructorParameters
File: accretion.halo.simple.F90
Used by:

Name: redshifts
Type: real 1..*
Default value: [0.0d0]
Description: A list of (space-separated) redshifts at which Galacticus results should be output. Redshifts need not be in any particular order.
Defined in: function:listConstructorParameters
File: output.times.list.F90
Used by:

Name: regridCount
Type: integer 1
Default value: 100
Description: Number of points in time to use when regridding merger trees.
Defined in: function:regridTimesConstructorParameters
File: merger_trees.operators.regrid_times.F90

Used by:

Name: `reionizationRedshift`
Type: real 1
Default value: 9.97 (Hinshaw et al. 2012; CMB+H_0+BAO)
Description: The redshift of reionization in the simple IGM state model.
Defined in: `function:simpleIGMConstructorParameters`
File: `intergalactic_medium.state.simple.F90`
Used by:

Name: `reionizationTemperature`
Type: real 1
Default value: 1.0×10^4
Description: The post-reionization temperature (in units of Kelvin) in the simple IGM state model.
Defined in: `function:simpleIGMConstructorParameters`
File: `intergalactic_medium.state.simple.F90`
Used by:

Name: `reportCount`
Type: integer 1
Default value: 10
Description: The number of steps between issuing reports.
Defined in: `function:particleSwarmConstructorParameters`
File: `posterior_sampling.simulation.particle_swarm.F90`
Used by:

Name: `rescaleMaximum`
Type: integer 0..
Default value: 20
Description: The maximum allowed number of tolerance rescalings.
Defined in: `function:augmentConstructorParameters`
File: `merger_trees.operators.augment.F90`
Used by:

Name: `restoreLevels`
Type: boolean 1
Default value: .true.
Description: If true the level reached by each chain is restored on restarts. Otherwise, the level is initialized to zero (which may be useful for stochastic likelihoods).
Defined in: `function:independentLikelihoodsSequentialConstructorParameters`
File: `models.likelihoods.independent_likelihoods.sequential.F90`
Used by:

Name: `restoreState`
Type: logical 1
Description: If true, restore the state of the simulation.
Defined in: `function:resumeConstructorParameters`
File: `posterior_sampling.state.initialize.resume.F90`
Used by:

Name: `resume`
Type: integer 1
Default value: .false.
Description: If true, resume from a previous set of log files.
Defined in: `function:particleSwarmConstructorParameters`
File: `posterior_sampling.simulation.particle_swarm.F90`
Used by:

Name: `retryMaximum`
Type: integer 0..
Default value: 50
Description: The number of tree build attempts to complete before rescaling the tolerance.
Defined in: `function:augmentConstructorParameters`
File: `merger_trees.operators.augment.F90`
Used by:

Name: `reweightTrees`
Type: boolean 1
Default value: .false.
Description: Specifies whether merger tree weights should be recomputed from the halo mass function.
Defined in: `function:galacticusConstructorParameters`
File: `merger_trees.construct.read.importer.galacticus.F90`
Used by:

Name: `rootVariance`
Type: float 0..1
Description: Root variance for the normal distribution weight operator.
Defined in: `function:normalConstructorParameters`
File: `galacticus.output.analyses.property_operator.normal.F90`
Used by:

Name: `running`
Type: real 0..1
Default value: 0.0
Description: The running, $\mathrm{d}n_\mathrm{s}/\mathrm{d}\ln k$, of the power spectrum index.
Defined in: `function:powerLawConstructorParameters`
File: `structure_formation.power_spectrum.primordial.power_law.F90`
Used by:

Name: `sample`
Type: string 1
Default value: var_str('SMCbar')
Description: The name of the sample from Gordon et al. [2003] to use in dust attenuation calculations.
Defined in: `function:gordon2003ConstructorParameters`
File: `stellar_populations.spectra.dust_attenuation.Gordon2003.F90`
Used by:

Name: `sampleOutliers`

Type: integer 1
Default value: .true.
Description: If true, sample from outlier states.
Defined in: function:differentialEvolutionConstructorParameters
File: posterior_sampling.simulation.differential_evolution.F90
Used by:

Name: sampleParticleNumber
Type: boolean 0..1
Default value: .false.
Description: If true, the number of particles in each halo will be sampled from a Poisson distribution with the expected mean. Otherwise, the number is set equal to that expectation.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: sampleRate
Type: integer 0..1
Default value: 1_c_size_t
Description: One in [sampleRate] particles will be sampled when computed environmental overdensities.
Defined in: function:environmentalOverdensityConstructorParameters
File: nBody.operator.environmental_overdensity.F90
Used by:

Name: satelliteBoundMassInitializeType
Type: string 1
Default value: var_str('basicMass')
Description: Specify how to initialize the bound mass of a satellite halo. By default, the initial bound mass of a satellite halo is set to the node mass.
Defined in: subroutine:Node_Component_Satellite_Orbiting_Initialize
File: objects.nodes.components.satellite.orbiting.F90
Used by:

Name: satelliteBoundMassIsInactive
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the bound mass variable of the standard satellite component is inactive (i.e. does not appear in any ODE being solved).
Defined in: subroutine:Node_Component_Satellite_Standard_Initialize
File: objects.nodes.components.satellite.standard.F90
Used by:

Name: satelliteDensityContrast
Type: double 1
Default value: 200.0
Description: The density contrast of the satellite halo. If [satelliteBoundMassInitializeType] is set to 'densityContrast', this value will be used to compute the initial bound mass of the satellite halo.
Defined in: subroutine:Node_Component_Satellite_Orbiting_Initialize

File: objects.nodes.components.satellite.orbiting.F90
Used by:

Name: satelliteMaximumRadiusOverVirialRadius
Type: double 1
Default value: 1.0
Description: The maximum radius of the satellite halo in units of its virial radius. If [satelliteBoundMassInitializeType] is set to 'maximumRadius', this value will be used to compute the initial bound mass of the satellite halo assuming that its density profile is 0 beyond this maximum radius.
Defined in: subroutine:Node_Component_Satellite_Orbiting_Initialize
File: objects.nodes.components.satellite.orbiting.F90
Used by:

Name: satelliteOffset
Type: boolean 0..1
Default value: .true.
Description: If true, offset particle representations to the positions/velocities of satellites.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: satelliteOrbitResetOnHaloFormation
Type: boolean 1
Default value: .false.
Description: Specifies whether satellite virial orbital parameters should be reset on halo formation events.
Defined in: subroutine:Node_Component_Satellite_Standard_Initialize
File: objects.nodes.components.satellite.standard.F90
Used by:

Name: satelliteOrbitStoreOrbitalParameters
Type: boolean 1
Default value: .true.
Description: Specifies whether satellite virial orbital parameters should be stored (otherwise they are computed again—possibly at random—each time they are requested).
Defined in: subroutine:Node_Component_Satellite_Standard_Initialize
File: objects.nodes.components.satellite.standard.F90
Used by:

Name: satelliteOrbitingDestructionMass
Type: double 1
Default value: 0.01
Description: The mass (possibly fractional—see [satelliteOrbitingDestructionMassIsFractional]) below which the satellite is considered to be tidally destroyed and merged with the central halo.
Defined in: subroutine:Node_Component_Satellite_Orbiting_Initialize
File: objects.nodes.components.satellite.orbiting.F90
Used by:

Name: satelliteOrbitingDestructionMassIsFractional

Type: double 1
Default value: .true.
Description: If true, then `[satelliteOrbitingDestructionMass]` specifies the fractional mass a halo must reach before it is tidally destroyed. Otherwise, `[satelliteOrbitingDestructionMass]` specifies an absolute mass.
Defined in: subroutine:Node_Component_Satellite_Orbiting_Initialize
File: objects.nodes.components.satellite.orbiting.F90
Used by:

Name: `satelliteOutputVirialOrbit`
Type: string 1
Default value: .false.
Description: Specifies whether the
normalfont
ttfamily virialOrbit method of the
normalfont
ttfamily standard implemention of the
normalfont
ttfamily component class should be output.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `scale`
Type: real 1
Description: The scale parameter of the Cauchy distribution function.
Defined in: function:cauchyConstructorParameters
File: statistics.distributions.Cauchy.F90
Used by:

Name: `scaleADAFRadiativeEfficiency`
Type: real 1
Default value: .true.
Description: Specifies whether the radiative efficiency of the ADAF component in a switched accretion disk scales with accretion rate.
Defined in: function:switchedConstructorParameters
File: accretion_disks.switched.F90
Used by:

Name: `scaleFactorExponent`
Type: integer 1
Description: The exponent of the cosmological scale factor needed to convert the velocities to physical units.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: `scaleHeight`
Type: real 1

Default value: 0.137 [Kregel et al., 2002]
Description: The scale height of the exponential disk profile.
Defined in: function:exponentialDiskConstructorParameters
File: mass_distributions.cylindrical.exponential_disk.F90
Used by:

Name: scaleLength
Type: real 1
Default value: 1.0
Description: The scale radius of the NFW profile.
Defined in: function:nfwConstructorParameters
File: mass_distributions.spherical.NFW.F90
Used by:

Name: scaleNodesByLogMass
Type: boolean 1
Default value: .true.
Description: Specifies whether or not node sizes should be scaled by the logarithm of their mass.
Defined in: function:dumpToGraphVizConstructorParameters
File: merger_trees.operators.dump_to_GraphViz.F90
Used by:

Name: scaleRadiiFailureIsFatal
Type: boolean 1
Default value: .true.
Description: Specifies whether failure to set a node scale radii should be regarded as a fatal error. (If not, a fallback method to set scale radius is used in such cases.)
Defined in: function:readConstructorParameters
File: merger_trees.construct.read.F90
Used by:

Name: scaleRadius
Type: real 1
Default value: 1.0
Description: The scale radius of the exponential disk profile.
Defined in: function:exponentialDiskConstructorParameters
File: mass_distributions.cylindrical.exponential_disk.F90
Used by:

Name: scatter
Type: string 1
Description: Scatter in the mass function incompleteness surface brightness model.
Defined in: function:surfaceBrightnessConstructorParameters
File: statistics.mass_function.incompleteness.surface_brightness.F90
Used by:

Name: scatterComment
Type: string 0..1
Description: A descriptive comment for the scatter.

Defined in: function:scatterFunction1DConstructorParameters
File: galacticus.output.analyses.scatter_function_1d.F90
Used by:

Name: scatterCovarianceTarget
Type: real 0..1
Description: The target function covariance for likelihood calculations.
Defined in: function:scatterFunction1DConstructorParameters
File: galacticus.output.analyses.scatter_function_1d.F90
Used by:

Name: scatterLabel
Type: string 0..1
Description: A label for the scatter.
Defined in: function:scatterFunction1DConstructorParameters
File: galacticus.output.analyses.scatter_function_1d.F90
Used by:

Name: scatterUnits
Type: string 0..1
Description: A human-readable description of the units for the scatter.
Defined in: function:scatterFunction1DConstructorParameters
File: galacticus.output.analyses.scatter_function_1d.F90
Used by:

Name: scatterUnitsInSI
Type: string 0..1
Description: A units for the scatter in the SI system.
Defined in: function:scatterFunction1DConstructorParameters
File: galacticus.output.analyses.scatter_function_1d.F90
Used by:

Name: scatterValueTarget
Type: real 0..1
Description: The target function for likelihood calculations.
Defined in: function:scatterFunction1DConstructorParameters
File: galacticus.output.analyses.scatter_function_1d.F90
Used by:

Name: selection
Type: string 0..1
Default value: var_str('all')
Description: Selects the type of halo to ouput. Allowed options are "all", "hosts", and "satellites".
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: selfBoundParticlesOnly
Type: logical 0..1

Description: If true, the velocity dispersion is computed only for self-bound particles.
Defined in: function:velocityDispersionConstructorParameters
File: nBody.operator.velocity_dispersion.F90
Used by:

Name: separationCount
Type: float 1
Default value: 15
Description: The number of bins in separation to compute in a mock catalog correlation function calculation.
Defined in: function:catalogProjectedCorrelationFunctionConstructorParameters
File: tasks.catalog_projected_correlation_function.F90
Used by:

Name: separationMaximum
Type: string 1
Description: The maximum separation at which to compute the projected correlation function.
Defined in: function:haloModelProjectedCorrelationFunctionConstructorParameters
File: tasks.halo_model.projected_correlation_function.F90
Used by:

Name: separationMinimum
Type: string 1
Description: The minimum separation at which to compute the projected correlation function.
Defined in: function:haloModelProjectedCorrelationFunctionConstructorParameters
File: tasks.halo_model.projected_correlation_function.F90
Used by:

Name: separationRadialMaximum
Type: float 1
Default value: 40.0
Description: The maximum radial separation of galaxies to consider when computing projected correlation functions.
Defined in: function:catalogProjectedCorrelationFunctionConstructorParameters
File: tasks.catalog_projected_correlation_function.F90
Used by:

Name: separations
Type: float 0..1
Description: The separations corresponding to bin centers.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: shape
Type: real 1
Description: The shape parameter of the gamma distribution function.
Defined in: function:gammaConstructorParameters
File: statistics.distributions.Gamma.F90

Used by:

Name: `sigma`
Type: real 1
Default value: 0.69
Description: The width of the lognormal part of the Chabrier [2001] IMF.
Defined in: `function:chabrier2001ConstructorParameters`
File: `stellar_populations.initial_mass_functions.Chabrier2001.F90`
Used by:

Name: `sigmaBuffer`
Type: real 1
Default value: 3.0
Description: The buffer size in units of the likelihood error to use when deciding whether to emulate the likelihood.
Defined in: `function:gaussianRegressionConstructorParameters`
File: `models.likelihoods.gaussian_regression.F90`
Used by:

Name: `sigmaLogMstar`
Type: real 1
Default value: 0.206 (Leauthaud et al. 2011; z_1 sample using their `SIG_MOD1` method)
Description: The parameter $\sigma_{\log M_\star}$ from the fitting functions of Behroozi et al. [2010].
Defined in: `function:behroozi2010ConstructorParameters`
File: `halo_model.conditional_mass_function.Behroozi2010.F90`
Used by:

Name: `sigmaRatioHigh`
Type: real 1
Default value: [+0.091d0,+0.139d0,+0.187d0]
Description: Values of the σ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.05–0.5 mass ratio.
Defined in: `function:jiang2014ConstructorParameters`
File: `satellites.merging.virial_orbits.Jiang2014.F90`
Used by:

Name: `sigmaRatioIntermediate`
Type: real 1
Default value: [+0.073d0,+0.083d0,+0.118d0]
Description: Values of the σ parameter of the Jiang et al. [2014] orbital velocity distribution for the three host halo mass ranges, and the 0.005–0.05 mass ratio.
Defined in: `function:jiang2014ConstructorParameters`
File: `satellites.merging.virial_orbits.Jiang2014.F90`
Used by:

Name: `sigmaRatioLow`
Type: real 1
Default value: [+0.077d0,+0.094d0,+0.072d0]
Description: Values of the σ parameter of the Jiang et al. [2014] orbital velocity distribution for the

three host halo mass ranges, and the 0.0001–0.005 mass ratio.
Defined in: function:jiang2014ConstructorParameters
File: satellites.merging.virial_orbits.Jiang2014.F90
Used by:

Name: sigma_8
Type: real 1
Default value: 0.8111 (Planck Collaboration et al. 2018; TT,TE,EE+lowE+lensing)
Description: The fractional mass fluctuation in the linear density field at the present day in spheres of radius 8 Mpc/h.
Defined in: function:filteredPowerConstructorParameters
File: structure_formation.cosmological_mass_variance.filtered_power_spectrum.F90
Used by:

Name: sizeGridFFT
Type: integer 1
Default value: 64
Description: The size of the FFT grid to use in computing window functions for mass function covariance matrices.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: sizeSource
Type: real 0..1
Default value: 0.001
Description: The source size to assume for gravitational lensing calculations.
Defined in: function:grvtnlLnsngConstructorParameters
File: galacticus.output.analyses.distribution_operator.gravitational_lensing.F90
Used by:

Name: sizeSourceLensing
Type: float 0..1
Default value: 2.0×10^{-3}
Description: The characteristic source size for gravitational lensing calculations.
Defined in: function:massFunctionStellarZFOURGEConstructorParameters
File: galacticus.output.analyses.mass_function_stellar.ZFOURGE.F90
Used by:

Name: slope
Type: string 1
Description: Slope of mass function incompleteness surface brightness model, i.e. α in $\mu(M) = \alpha \log_{10}(M/M_0) + \beta$.
Defined in: function:surfaceBrightnessConstructorParameters
File: statistics.mass_function.incompleteness.surface_brightness.F90
Used by:

Name: smoothAccretion
Type: boolean 1

Default value: .true.
Description: Specifies whether or not to include smooth accretion in subresolution accretion rates when constructing merger trees using the generalized Press-Schechter branching algorithm.
Defined in: function:generalizedPressSchechterConstructorParameters
File: merger_trees.branching_probability.generalized_Press_Schechter.F90
Used by:

Name: snapTolerance
Type: real 1
Default value: 0.0
Description: The fractional tolerance used in deciding if a node should be snapped to a time on the grid.
Defined in: function:regridTimesConstructorParameters
File: merger_trees.operators.regrid_times.F90
Used by:

Name: snapshotRedshifts
Type: real 0..
Description: The redshifts at which merger trees are to regridded when the [snapshotSpacing]=list option is selected.
Defined in: function:regridTimesConstructorParameters
File: merger_trees.operators.regrid_times.F90
Used by:

Name: snapshotSpacing
Type: string 1
Default value: var_str('logarithmic')
Description: Type of spacing to use in merger tree regridding (linear or logarithmic).
Defined in: function:regridTimesConstructorParameters
File: merger_trees.operators.regrid_times.F90
Used by:

Name: solutionTolerance
Type: real 1
Default value: 1.0×10^{-2}
Description: Maximum allowed mean fractional error in the radii of all components when seeking equilibrium solutions for galactic structure.
Defined in: function:equilibriumConstructorParameters
File: galactic_structure.radius_solver.equilibrium.F90
Used by:

Name: solveForInactiveProperties
Type: boolean 1
Default value: .true.
Description: If true, galactic structure is solved for during evaluation of inactive property integrals. Otherwise, structure is not solved for during this phase—this should only be used if the inactive property integrands *do not* depend on galactic structure.
Defined in: function:equilibriumConstructorParameters
File: galactic_structure.radius_solver.equilibrium.F90

Used by:

Name: `sourceAngularMomentumSpecificMean`
Type: string 1
Default value: var_str('hotGas')
Description: The component ("`hotGas`" or "`darkMatter`") from which the mean specific angular momentum should be computed for calculations of cooling gas specific angular momentum.
Defined in: function:constantRotationConstructorParameters
File: cooling.specific_angular_momentum.constant_rotation.F90
Used by:

Name: `sourceNormalizationRotation`
Type: string 1
Default value: var_str('hotGas')
Description: The component ("`hotGas`" or "`darkMatter`") from which the constant rotation speed should be computed for calculations of cooling gas specific angular momentum.
Defined in: function:constantRotationConstructorParameters
File: cooling.specific_angular_momentum.constant_rotation.F90
Used by:

Name: `spheroidAngularMomentumAtScaleRadius`
Type: double 1
Default value: spheroidAngularMomentumAtScaleRadiusDefault (I_2/I_3 where $I_n = \int_0^\infty \rho(r) r^n \mathrm{d}r$, where $\rho(r)$ is the spheroid density profile, unless either I_2 or I_3 is infinite, in which case a default of $1/2$ is used instead.)
Description: The assumed ratio of the specific angular momentum at the scale radius to the mean specific angular momentum of the standard spheroid component.
Defined in: subroutine:Node_Component_Spheroid_Standard_Thread_Initialize
File: objects.nodes.components.spheroid.standard.F90
Used by:

Name: `spheroidEnergeticOutflowMassRate`
Type: double 1
Default value: 1.0×10^{-2}
Description: The proportionallity factor relating mass outflow rate from the spheroid to the energy input rate divided by $V^2_{\rm spheroid}$.
Defined in: subroutine:Node_Component_Spheroid_Standard_Initialize
File: objects.nodes.components.spheroid.standard.F90
Used by:

Name: `spheroidLuminositiesStellarInactive`
Type: boolean 1
Default value: .false.
Description: Specifies whether or not spheroid stellar luminosities are inactive properties (i.e. do not appear in any ODE being solved).
Defined in: subroutine:Node_Component_Spheroid_Standard_Initialize
File: objects.nodes.components.spheroid.standard.F90
Used by:

Name: spheroidMassToleranceAbsolute
Type: double 1
Default value: 1.0×10^{-6}
Description: The mass tolerance used to judge whether the spheroid is physically plausible.
Defined in: subroutine:Node_Component_Spheroid_Standard_Initialize
File: objects.nodes.components.spheroid.standard.F90
Used by:

Name: spheroidOutflowTimescaleMinimum
Type: double 1
Default value: 1.0×10^{-3}
Description: The minimum timescale (in units of the spheroid dynamical time) on which outflows may deplete gas in the spheroid.
Defined in: subroutine:Node_Component_Spheroid_Standard_Initialize
File: objects.nodes.components.spheroid.standard.F90
Used by:

Name: spheroidOutputStarFormationRate
Type: string 1
Default value: .false.
Description: Specifies whether the
normalfont
ttfamily starFormationRate method of the
normalfont
ttfamily standard implemention of the
normalfont
ttfamily component class should be output.
Defined in: subroutine:nodeClassHierarchyInitialize
File: objects.nodes.components.Inc
Used by:

Name: spheroidRadiusFraction
Type: real 1
Default value: 0.0
Description: The fraction of the spheroid radius at which merging black holes will be initially placed.
Defined in: function:spheroidRadiusFractionConstructorParameters
File: black_holes.binaries.initial_separation.spheroid_size_fraction.F90
Used by:

Name: spheroidStarFormationInSatellites
Type: boolean 1
Default value: .true.
Description: Specifies whether or not star formation occurs in spheroids in satellites.
Defined in: subroutine:Node_Component_Spheroid_Standard_Initialize
File: objects.nodes.components.spheroid.standard.F90
Used by:

Name: spheroidStarFormationTimescaleMinimum
Type: double 1

Default value: 1.0×10^{-3}
Description: The minimum timescale (in units of the halo dynamical time) on which star formation may occur in the spheroid.
Defined in: subroutine:Node_Component_Spheroid_Very_Simple_Initialize
File: objects.nodes.components.spheroid.very_simple.F90
Used by:

Name: spheroidToTotalRatioThreshold
Type: real 0..1
Description: The parameter R_0 appearing in the stellar mass-weight morphology threshold for the stellar mass-weighted morphology galactic filter class.
Defined in: function:stellarMassMorphologyConstructorParameters
File: galactic.filters.stellar_mass_morphology.F90
Used by:

Name: spheroidVerySimpleMassScaleAbsolute
Type: double 1
Default value: 100.0
Description: The absolute mass scale below which calculations in the very simple spheroid component are allowed to become inaccurate.
Defined in: subroutine:Node_Component_Spheroid_Very_Simple_Initialize
File: objects.nodes.components.spheroid.very_simple.F90
Used by:

Name: spheroidVerySimpleTrackAbundances
Type: boolean 0..1
Default value: .false.
Description: Specifies whether or not to track abundances in the very simple spheroid component.
Defined in: subroutine:Node_Component_Spheroid_Very_Simple_Initialize
File: objects.nodes.components.spheroid.very_simple.F90
Used by:

Name: spheroidVerySimpleTrackLuminosities
Type: boolean 0..1
Default value: .false.
Description: Specifies whether or not to track stellar luminosities in the very simple disk component.
Defined in: subroutine:Node_Component_Spheroid_Very_Simple_Initialize
File: objects.nodes.components.spheroid.very_simple.F90
Used by:

Name: spin
Type: real 1
Default value: 0.03687 [Bett et al., 2007]
Description: The fixed value of spin in a δ-function spin distribution.
Defined in: function:deltaFunctionConstructorParameters
File: dark_matter_halos.spins.distributions.delta_function.F90
Used by:

Name: spinMaximum

Type: real 0..1
Default value: 0.5
Description: Maximum spin for which the distribution function should be calculated.
Defined in: function:haloSpinDistributionConstructorParameters
File: tasks.halo_spin_distribution.F90
Used by:

Name: spinMinimum
Type: real 0..1
Default value: 3.0×10^{-4}
Description: Minimum spin for which the distribution function should be calculated.
Defined in: function:haloSpinDistributionConstructorParameters
File: tasks.halo_spin_distribution.F90
Used by:

Name: spinPointsPerDecade
Type: real 0..1
Default value: 10.0
Description: Number of points per decade of spin at which to calculate the distribution.
Defined in: function:haloSpinDistributionConstructorParameters
File: tasks.halo_spin_distribution.F90
Used by:

Name: spinVitvitskaMassExponent
Type: double 1
Default value: 1.0
Description: The exponent of mass ratio appearing in the orbital angular momentum term in the Vitvitska spin model.
Defined in: subroutine:Node_Component_Spin_Vitvitska_Bindings
File: objects.nodes.components.spin.Vitvitska.F90
Used by:

Name: stabilityThresholdGaseous
Type: real 1
Default value: 0.7
Description: The stability threshold in the Efstathiou et al. [1982] algorithm for purely gaseous disks.
Defined in: function:efstathiou1982ConstructorParameters
File: galactic_dynamics.bar_instability.Efstathiou1982.F90
Used by:

Name: stabilityThresholdStellar
Type: real 1
Default value: 1.1
Description: The stability threshold in the Efstathiou et al. [1982] algorithm for purely stellar disks.
Defined in: function:efstathiou1982ConstructorParameters
File: galactic_dynamics.bar_instability.Efstathiou1982.F90
Used by:

Name: starFormationFrequencyNormalization

Type: real 1
Default value: 5.25×10^{-10} [Leroy et al., 2008]
Description: The star formation frequency (in the low-density limit and in units of yr^{-1}) in the "Blitz-Rosolowsky2006" star formation timescale calculation.
Defined in: function:blitz2006ConstructorParameters
File: star_formation.rate_surface_density.disks.Blitz2006.F90
Used by:

Name: startTime
Type: string 1
Description: The definition of start time (absolute time or age).
Defined in: function:sedFitConstructorParameters
File: models.likelihoods.SED_fit.F90
Used by:

Name: starveSatellites
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the hot halo should be removed ("starved") when a node becomes a satellite.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: starveSatellitesOutflowed
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the outflowed hot halo should be removed ("starved") when a node becomes a satellite.
Defined in: subroutine:Node_Component_Hot_Halo_Standard_Initialize
File: objects.nodes.components.hot_halo.standard.F90
Used by:

Name: stateFileRoot
Type: string 1
Default value: var_str('none')
Description: The root name of files to which the internal state is written (to permit restarts).
Defined in: subroutine:State_Initialize
File: galacticus.state.F90
Used by:

Name: stateRetrieveFileRoot
Type: string 1
Default value: var_str('none')
Description: The root name of files to which the internal state is retrieved from (to restart).
Defined in: subroutine:State_Initialize
File: galacticus.state.F90
Used by:

Name: `stateSwapCount`
Type: integer 1
Default value: 10
Description: The number of steps between state swap steps.
Defined in: function:differentialEvolutionConstructorParameters
File: posterior_sampling.simulation.differential_evolution.F90
Used by:

Name: `stellarDensityChangeBinaryMotion`
Type: boolean 1
Default value: .true.
Description: The change in density due to the black hole's motion.
Defined in: function:standardConstructorParameters
File: black_holes.binaries.separation_growth_rate.standard.F90
Used by:

Name: `stellarPopulationLuminosityIntegrationToleranceDegrade`
Type: real 1
Default value: .false.
Description: If `true`, automatically degrade the relative tolerance used when integrating the flux of stellar populations through filters to ensure convergence.
Defined in: subroutine:Stellar_Population_Luminosity_Tabulate
File: stellar_populations.luminosities.F90
Used by:

Name: `stellarPopulationLuminosityIntegrationToleranceRelative`
Type: real 1
Default value: 4.0×10^{-3}
Description: The relative tolerance used when integrating the flux of stellar populations through filters.
Defined in: subroutine:Stellar_Population_Luminosity_Tabulate
File: stellar_populations.luminosities.F90
Used by:

Name: `stellarPopulationLuminosityMaximumAgeExceededIsFatal`
Type: boolean 1
Default value: .true.
Description: Specifies whether or not exceeding the maximum available age of the stellar population is fatal.
Defined in: subroutine:Stellar_Population_Luminosity_Tabulate
File: stellar_populations.luminosities.F90
Used by:

Name: `stellarPopulationLuminosityStoreDirectory`
Type: string 1
Default value: galacticusPath(pathTypeDataDynamic)//'stellarPopulations'
Description: Specifies the directory to which stellar populations luminosities (integrated under a filter) should be stored to file for rapid reuse.
Defined in: subroutine:Stellar_Population_Luminosity_Tabulate
File: stellar_populations.luminosities.F90

Used by:

Name: `stellarPopulationLuminosityStoreToFile`
Type: boolean 1
Default value: .true.
Description: Specifies whether or not stellar populations luminosities (integrated under a filter) should be stored to file for rapid reuse.
Defined in: `subroutine:Stellar_Population_Luminosity_Tabulate`
File: `stellar_populations.luminosities.F90`
Used by:

Name: `stepsMaximum`
Type: integer 1
Default value: huge(0)
Description: The maximum number of steps to take.
Defined in: `function:particleSwarmConstructorParameters`
File: `posterior_sampling.simulation.particle_swarm.F90`
Used by:

Name: `stepsPerLevel`
Type: integer 1
Default value: 10
Description: The number of steps to take at each tempering level.
Defined in: `function:temperedDifferentialEvolutionConstructorParameters`
File: `posterior_sampling.simulation.tempered_differential_evolution.F90`
Used by:

Name: `stopAfterCount`
Type: real 1
Description: The number of steps to continue after convergence before stopping.
Defined in: `function:stepCountConstructorParameters`
File: `posterior_sampling.stopping_criteria.step_count.F90`
Used by:

Name: `stride`
Type: integer 1
Description: The size of the stride to take over forests.
Defined in: `function:strideConstructorParameters`
File: `tasks.evolve_forests.work_share.stride.F90`
Used by:

Name: `subhaloAngularMomentaMethod`
Type: boolean 1
Default value: var_str('summation')
Description: Specifies how to account for subhalo angular momentum when adding subhalo mass to host halo mass.
Defined in: `function:readConstructorParameters`
File: `merger_trees.construct.read.F90`
Used by:

Name: `subhaloHierarchyDepth`
Type: integer 1
Default value: 2
Description: The depth in the subhalo hierarchy for which to store unevolved subhalo mass functions.
Defined in: `function:conditionalMFConstructorParameters`
File: `merger_trees.operators.conditional_mass_function.F90`
Used by:

Name: `subtractRandomOffset`
Type: boolean 0..1
Default value: .false.
Description: If true, the center-of-mass postions and velocities of the host and satellite are enforced to be matched with the values specified by the offset parameters. If false, due to limited number of particles in the representations, the center-of-mass postions and velocities may deviate slightly from the specified values, i.e. have small random offsets.
Defined in: `function:particulateConstructorParameters`
File: `merger_trees.operators.particulate.F90`
Used by:

Name: `subvolumeBuffer`
Type: boolean 1
Default value: 0.0
Description: Specifies the buffer region (in units of Mpc/h to follow the format convention) around subvolumes of a "Sussing Merger Trees" format [Srisawat et al., 2013] merger tree file which should be read in to ensure that no halos are missed from trees.
Defined in: `function:sussingConstructorParameters`
File: `merger_trees.construct.read.importer.SussingMergerTrees.F90`
Used by:

Name: `subvolumeCount`
Type: boolean 1
Default value: 1
Description: Specifies the number of subvolumes *along each axis* into which a "Sussing Merger Trees" format [Srisawat et al., 2013] merger tree files should be split for processing through Galacticus.
Defined in: `function:sussingConstructorParameters`
File: `merger_trees.construct.read.importer.SussingMergerTrees.F90`
Used by:

Name: `subvolumeIndex`
Type: boolean 1
Default value: [0,0,0]
Description: Specifies the index (in each dimension) of the subvolume of a "Sussing Merger Trees" format [Srisawat et al., 2013] merger tree file to process. Indices range from 0 to `[subvolumeCount]`-1.
Defined in: `function:sussingConstructorParameters`
File: `merger_trees.construct.read.importer.SussingMergerTrees.F90`
Used by:

Name: `supernovaEnergy`

Type: real 1
Default value: 1.0×10^{51}
Description: The energy produced by a supernova (in ergs).
Defined in: function:standardConstructorParameters
File: stellar_astrophysics.feedback.standard.F90
Used by:

Name: surfaceBrightnessLimit
Type: real 1
Description: The limiting surface brightness to which to integrate.
Defined in: function:massFunctionConstructorParameters
File: models.likelihoods.mass_function.F90
Used by:

Name: surfaceDensityCritical
Type: real 1
Default value: 200.0 [Bigiel et al., 2008]
Description: The surface density (in units of $M_\odot$ pc^{-2}) in the "Blitz-Rosolowsky2006" star formation timescale calculation at which low-density truncation begins.
Defined in: function:blitz2006ConstructorParameters
File: star_formation.rate_surface_density.disks.Blitz2006.F90
Used by:

Name: surfaceDensityExponent
Type: real 1
Default value: 0.4 [Bigiel et al., 2008]
Description: The exponent for surface density in the "Blitz-Rosolowsky2006" star formation timescale calculation at in the high density regime.
Defined in: function:blitz2006ConstructorParameters
File: star_formation.rate_surface_density.disks.Blitz2006.F90
Used by:

Name: surveyRedshiftMaximum
Type: boolean 1
Default value: 0.1
Description: The maximum redshift at which calculations of the mass function covariance should be carried out.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: surveyRedshiftMinimum
Type: boolean 1
Default value: 0.0
Description: The minimum redshift at which calculations of the mass function covariance should be carried out.
Defined in: function:massFunctionCovarianceConstructorParameters
File: tasks.mass_function_covariance.F90
Used by:

Name: suspendPath
Type: string 1
Description: The path to which tree suspension files will be stored.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: suspendToRAM
Type: boolean 1
Default value: .true.
Description: Specifies whether trees should be suspended to RAM (otherwise they are suspend to file).
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: system
Type: real 1..*
Description: The photometric system (AB or Vega) of the broad-band SED.
Defined in: function:sedFitConstructorParameters
File: models.likelihoods.SED_fit.F90
Used by:

Name: systematicErrorPolynomialCoefficient
Type: float 0..1
Default value: [0.0d0]
Description: The coefficients of the systematic error polynomial for stellar vs halo mass relation.
Defined in: function:stellarVsHaloMassRelationLeauthaud2012ConstructorParameters
File: galacticus.output.analyses.stellar_vs_halo_mass_relation.COSMOS_Leauthaud2012.F90
Used by:

Name: tablePointsPerDecade
Type: integer 0..1
Default value: 10
Description: The number of points per decade of wavenumber at which to tabulate the transfer function.
Defined in: function:acceleratorConstructorParameters
File: structure_formation.transfer_function.accelerator.F90
Used by:

Name: tableStore
Type: boolean 0..1
Default value: .true.
Description: If true, store/restore the tabulated solution to/from file when possible.
Defined in: function:sphericalCollapseMatterLambdaConstructorParameters
File: structure_formation.virial_density_contrast.spherical_collapse_matter_lambda.F90
Used by:

Name: targetLabel

Type: string 0..1
Default value: var_str('')
Description: A label for the target dataset in a plot of this analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: temperature
Type: real 1
Description: The temperature of the black body radiation field.
Defined in: function:blackBodyConstructorParameters
File: radiation.black_body.F90
Used by:

Name: temperatureCMB
Type: real 0..1
Default value: 2.72548 [Fixsen, 2009]
Description: The present day temperature of the cosmic microwave background (CMB) in units of Kelvin.
Defined in: function:simpleConstructorParameters
File: cosmology.parameters.simple.F90
Used by:

Name: temperatureLevelCount
Type: integer 1
Default value: 10
Description: The number temperature levels to use.
Defined in: function:annealedDifferentialEvolutionConstructorParameters
File: posterior_sampling.simulation.annealed_differential_evolution.F90
Used by:

Name: temperatureMaximum
Type: integer 1
Description: The maximum temperature to reach.
Defined in: function:temperedDifferentialEvolutionConstructorParameters
File: posterior_sampling.simulation.tempered_differential_evolution.F90
Used by:

Name: temperatureScale
Type: integer 1
Description: The temperature scale.
Defined in: function:stochasticDifferentialEvolutionConstructorParameters
File: posterior_sampling.simulation.stochastic_differential_evolution.F90
Used by:

Name: temperingLevelCount
Type: integer 1
Default value: 10
Description: The number tempering levels to use.

Defined in: function:temperedDifferentialEvolutionConstructorParameters
File: posterior_sampling.simulation.tempered_differential_evolution.F90
Used by:

Name: testCount
Type: integer 1
Default value: 10
Description: The interval in number of steps at which to check convergence.
Defined in: function:gelmanRubinConstructorParameters
File: posterior_sampling.convergence.Gelman-Rubin.F90
Used by:

Name: threadLock
Type: boolean 1
Default value: .false.
Description: Specifies whether or not to limit the number of threads across all Galacticus processes.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: threadLockName
Type: string 1
Default value: var_str('galacticus')
Description: The name to use for the semaphore used to lock threads across all Galacticus processes.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: threadsMaximum
Type: string 1
Default value: var_str('processorCount')
Description: The maximum number of active threads across all Galacticus processes.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: thresholdCollapse
Type: real 1
Description: The threshold for collapse of density perturbations.
Defined in: function:peakBackgroundConstructorParameters
File: statistics.distributions.peak_background.F90
Used by:

Name: thresholdHatR
Type: real 1
Default value: 1.2
Description: The $\hat{R}$ value at which convergence is declared.
Defined in: function:gelmanRubinConstructorParameters
File: posterior_sampling.convergence.Gelman-Rubin.F90

Used by:

Name: `thresholdMaximum`
Type: float 0..1
Description: Maximum threshold for the min-max property operator.
Defined in: `function:minMaxConstructorParameters`
File: `galacticus.output.analyses.property_operator.minmax.F90`
Used by:

Name: `thresholdMinimum`
Type: float 0..1
Description: Minimum threshold for the min-max property operator.
Defined in: `function:minMaxConstructorParameters`
File: `galacticus.output.analyses.property_operator.minmax.F90`
Used by:

Name: `thresholdStabilityShock`
Type: real 1
Default value: 0.0126 [Birnboim and Dekel, 2003]
Description: The threshold value, $\epsilon_{\rm s,crit}$, for shock stability in the model of Birnboim and Dekel [2003].
Defined in: `function:coldModeConstructorParameters`
File: `accretion.halo.cold_mode.F90`
Used by:

Name: `timeBegin`
Type: real 1
Default value: 0.05d0*ageUniverse
Description: The earliest time at which to tabulate the evolution of main branch progenitor galaxies (in Gyr).
Defined in: `function:recordEvolutionConstructorParameters`
File: `merger_trees.evolve.timesteps.record_evolution.F90`
Used by:

Name: `timeBinsPerDecade`
Type: integer 1
Default value: 10
Description: The number of bins per decade of time at which to count non-primary progenitors.
Defined in: `function:profilerConstructorParameters`
File: `merger_trees.operators.profiler.F90`
Used by:

Name: `timeCountPerDecade`
Type: integer 1
Default value: 10
Description: The number of bins per decade of time to use for calculations of the properties of the universe.
Defined in: `function:intergalacticMediumStateEvolveConstructorParameters`
File: `universe.operators.intergalactic_medium_state_evolve.F90`
Used by:

Name: `timeEnd`
Type: real 1
Default value: ageUniverse
Description: The latest time at which to tabulate the evolution of main branch progenitor galaxies (in Gyr).
Defined in: function:recordEvolutionConstructorParameters
File: merger_trees.evolve.timesteps.record_evolution.F90
Used by:

Name: `timeEvolvesAlongLightcone`
Type: real 0..1
Default value: .true.
Description: If `true`, cosmic time evolves along the lightcone as expected. Otherwise, time is fixed at the present epoch throughout the lightone. This allows construction of lightcones with no evolution.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: `timeFine`
Type: real 1
Default value: 0.1
Description: The period prior to each output for which the fine time step is used in tabulations of star formation histories [Gyr].
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90
Used by:

Name: `timeFormationSeekDelta`
Type: real 1
Default value: 0.0
Description: The parameter $\Delta \log t$ by which the logarithm of the trial formation time is incremented when stepping through the formation history of a node to find the formation time. If set to zero (or a negative value) the cumulative mass histories of nodes are assumed to be monotonic functions of time, and the formation time is instead found by a root finding algorithm,
Defined in: function:ludlow2016ConstructorParameters
File: dark_matter_profiles.structure.scale.Ludlow2016.F90
Used by:

Name: `timeLimit`
Type: real 1
Default value: 1.0×10^{-2}
Description: The maximum age of stellar populations to retain in the "recent" spectra postprocessing method.
Defined in: function:recentConstructorParameters
File: stellar_populations.spectra.postprocess.recent.F90
Used by:

Name: `timeOffsetMaximumAbsolute`

Type: real 1
Default value: 0.010
Description: The maximum absolute time difference (in Gyr) allowed between merging pairs of galaxies.
Defined in: function:satelliteConstructorParameters
File: merger_trees.evolve.timesteps.satellite.F90
Used by:

Name: timeOffsetMaximumRelative
Type: real 1
Default value: 0.001
Description: The maximum time difference (relative to the cosmic time at the merger epoch) allowed between merging pairs of galaxies.
Defined in: function:satelliteConstructorParameters
File: merger_trees.evolve.timesteps.satellite.F90
Used by:

Name: timeRecent
Type: real 0..1
Description: Halos which experienced a major node merger within a time $\Delta t =$[timeRecent] of the analysis time will be excluded from the analysis.
Defined in: function:spinDistributionBett2007ConstructorParameters
File: galacticus.output.analyses.spin_distribution.Bett2007.F90
Used by:

Name: timeScale
Type: real 0..1
Default value: 1.0
Description: The timescale (in Gyr) for cooling in the simple cooling rate model.
Defined in: function:simpleConstructorParameters
File: cooling.cooling_rate.simple.F90
Used by:

Name: timeSnapTolerance
Type: real 1
Default value: 1.0×10^{-6}
Description: The fractional tolerance within which the tree base time will be snapped to a nearby output time.
Defined in: function:buildConstructorParameters
File: merger_trees.construct.build.F90
Used by:

Name: timeSnapshot
Type: real 0..1
Description: The time at which to snapshot the tree.
Defined in: function:particulateConstructorParameters
File: merger_trees.operators.particulate.F90
Used by:

Name: timeStart

Type: float 1
Description: The time at which two-body relaxation is assumed to have begun.
Defined in: function:twoBodyRelaxationConstructorParameters
File: dark_matter_profiles.heating.two_body_relaxation.F90
Used by:

Name: timeStep
Type: real 1
Default value: 0.1
Description: The time step to use in tabulations of star formation histories [Gyr].
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90
Used by:

Name: timeStepAbsolute
Type: real 1
Default value: 1.0
Description: The maximum allowed absolute change in time (in Gyr) for a single step in the evolution of a node.
Defined in: function:simpleConstructorParameters
File: merger_trees.evolve.timesteps.simple.F90
Used by:

Name: timeStepFine
Type: real 1
Default value: 0.01
Description: The fine time step to use in tabulations of star formation histories [Gyr].
Defined in: function:metallicitySplitConstructorParameters
File: star_formation.histories.metallicity_split.F90
Used by:

Name: timeStepFractional
Type: real 0..1
Default value: 0.01
Description: The fractional time step used when computing barrier crossing rates (i.e. the step used in finite difference calculations).
Defined in: function:farahiConstructorParameters
File: structure_formation.excursion_sets.first_crossing_distribution.Farahi.F90
Used by:

Name: timeStepRelative
Type: real 1
Default value: 0.1
Description: The maximum allowed relative change in time for a single step in the evolution of a node.
Defined in: function:simpleConstructorParameters
File: merger_trees.evolve.timesteps.simple.F90
Used by:

Name: times

Type: real 1..*
Description: A list of (space-separated) times at which Galacticus results should be output. Times need not be in any particular order.
Defined in: function:listConstructorParameters
File: output.times.list.F90
Used by:

Name: timesPerDecade
Type: integer 1
Default value: 10
Description: The number of points per decade of time at which to tabulate excursion set solutions.
Defined in: function:excursionSetsConstructorParameters
File: tasks.excursion_sets.F90
Used by:

Name: timescale
Type: real 1
Default value: 1.0×10^{-2}
Description: The timescale for "escape" of stellar populations in the "unescaped" spectra postprocessing method.
Defined in: function:unescapedConstructorParameters
File: stellar_populations.spectra.postprocess.unescaped.F90
Used by:

Name: timescaleMinimum
Type: real 1
Default value: 0.001
Description: The minimum timescale (in Gyr) for cooling the velocity maximum scaling scaling cooling rate model.
Defined in: function:velocityMaximumScalingConstructorParameters
File: cooling.cooling_rate.velocity_maximum_scaling.F90
Used by:

Name: timescaleMultiplier
Type: real 1
Default value: 0.75
Description: A multiplier for the merging timescale in dynamical friction timescale calculations.
Defined in: function:wetzelWhite2010ConstructorParameters
File: satellites.merging.timescale.Wetzel-White.F90
Used by:

Name: timescaleNormalization
Type: real 1
Default value: 0.13
Description: The mass loss timescale normalization (in Gyr) for the van den Bosch et al. [2005] dark matter halo mass loss rate algorithm.
Defined in: function:vanDenBoschConstructorParameters
File: dark_matter_halos.mass_loss_rates.vanDenBosch.F90
Used by:

Name: `timestepHostAbsolute`
Type: real 1
Default value: 1.0
Description: The maximum allowed absolute timestep (in Gyr) for node evolution relative to the time of the host halo.
Defined in: function:standardConstructorParameters
File: merger_trees.evolver.standard.F90
Used by:

Name: `timestepHostRelative`
Type: real 1
Default value: 0.1
Description: The maximum allowed relative timestep for node evolution relative to the time of the host halo.
Defined in: function:standardConstructorParameters
File: merger_trees.evolver.standard.F90
Used by:

Name: `tolerance`
Type: real 1
Default value: 4.0×10^{-6}
Description: The relative tolerance to use in integrating over the linear power spectrum to compute the cosmological mass variance.
Defined in: function:filteredPowerConstructorParameters
File: structure_formation.cosmological_mass_variance.filtered_power_spectrum.F90
Used by:

Name: `toleranceResolutionParent`
Type: real 0..1
Default value: 1.0×10^{-3}
Description: The fractional tolerance in parent node mass at the resolution limit below which branch mis-orderings will be ignored.
Defined in: function:cole2000ConstructorParameters
File: merger_trees.construct.builder.Cole2000.F90
Used by:

Name: `toleranceResolutionSelf`
Type: real 0..1
Default value: 1.0×10^{-6}
Description: The fractional tolerance in node mass at the resolution limit below which branch mis-orderings will be ignored.
Defined in: function:cole2000ConstructorParameters
File: merger_trees.construct.builder.Cole2000.F90
Used by:

Name: `toleranceScale`
Type: real 0..
Default value: 0.15

Description: The tolerance scale used in deciding if a trial tree is an acceptable match.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: toleranceTopHat
Type: real 1
Default value: 1.0×10^{-6}
Description: The relative tolerance to use in integrating over the linear power spectrum using a top-hat (real space) window function to compute the cosmological mass variance.
Defined in: function:filteredPowerConstructorParameters
File: structure_formation.cosmological_mass_variance.filtered_power_spectrum.F90
Used by:

Name: toomreParameterCritical
Type: real 1
Default value: 0.4 [Kennicutt, 1989]
Description: The critical Toomre parameter for star formation in disks.
Defined in: function:kennicuttSchmidtConstructorParameters
File: star_formation.rate_surface_density.disks.Kennicutt-Schmidt.F90
Used by:

Name: topLevel
Type: boolean 1
Default value: .false.
Description: If true, output the index of the host at the top level of the hierarchy, otherwise output the index of the direct host.
Defined in: function:indicesHostConstructorParameters
File: nodes.property_extractor.hosts.F90
Used by:

Name: treeBeginAt
Type: integer 1
Default value: 0
Description: The index (in order of increasing base halo mass) of the tree at which to begin when building merger trees. A value of "0" means to begin with tree number 1 (if processing trees in ascending order), or equal to the number of trees (otherwise).
Defined in: function:buildConstructorParameters
File: merger_trees.construct.build.F90
Used by:

Name: treeCount
Type: float 1
Default value: spread(1,1,fixedHalosCount)
Description: Specifies the number of halos to use when building halos.
Defined in: function:fixedMassConstructorParameters
File: merger_trees.construct.build.masses.fixed_mass.F90
Used by:

Name: `treeIndexToRootNodeIndex`
Type: boolean 1
Default value: .false.
Description: Specifies whether tree indices should always be set to the index of their root node.
Defined in: `function:readConstructorParameters`
File: `merger_trees.construct.read.F90`
Used by:

Name: `treeNodeMethodAgeStatistics`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the ageStatistics component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodBasic`
Type: string 1
Default value: var_str('standard')
Description: Specifies the implementation to be used for the basic component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodBlackHole`
Type: string 1
Default value: var_str('standard')
Description: Specifies the implementation to be used for the blackHole component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodDarkMatterProfile`
Type: string 1
Default value: var_str('scale')
Description: Specifies the implementation to be used for the darkMatterProfile component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodDisk`
Type: string 1
Default value: var_str('standard')
Description: Specifies the implementation to be used for the disk component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodDynamicsStatistics`

Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the dynamicsStatistics component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodFormationTime`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the formationTime component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodHostHistory`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the hostHistory component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodHotHalo`
Type: string 1
Default value: var_str('standard')
Description: Specifies the implementation to be used for the hotHalo component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodIndices`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the indices component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodInterOutput`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the interOutput component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodMassFlowStatistics`
Type: string 1

Default value: var_str('null')
Description: Specifies the implementation to be used for the massFlowStatistics component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodMergingStatistics`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the mergingStatistics component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodNBody`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the nBody component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodPosition`
Type: string 1
Default value: var_str('null')
Description: Specifies the implementation to be used for the position component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodSatellite`
Type: string 1
Default value: var_str('standard')
Description: Specifies the implementation to be used for the satellite component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodSpheroid`
Type: string 1
Default value: var_str('standard')
Description: Specifies the implementation to be used for the spheroid component of nodes.
Defined in: `subroutine:nodeClassHierarchyInitialize`
File: `objects.nodes.components.Inc`
Used by:

Name: `treeNodeMethodSpin`
Type: string 1
Default value: var_str('random')

Description: Specifies the implementation to be used for the spin component of nodes.
Defined in: subroutine:nodeClassHierarchyInitialize
File: objects.nodes.components.Inc
Used by:

Name: treeSampleRate
Type: float 1
Default value: 1.0
Description: Specify the probability that any given tree should processed (to permit subsampling).
Defined in: function:sussingConstructorParameters
File: merger_trees.construct.read.importer.SussingMergerTrees.F90
Used by:

Name: treesPerDecade
Type: real 1
Default value: 10.0
Description: The number of merger trees masses to sample per decade of base halo mass.
Defined in: function:sampledDistributionConstructorParameters
File: merger_trees.construct.build.masses.sampled_distribution.F90
Used by:

Name: tripleBlackHoleInteraction
Type: boolean 1
Default value: .false.
Description: Determines whether or not triple black hole interactions will be accounted for.
Defined in: subroutine:Node_Component_Black_Hole_Noncentral_Initialize
File: objects.nodes.components.black_hole.non_central.F90
Used by:

Name: truncate
Type: boolean 1
Default value: .true.
Description: Specifies whether or not to truncate star formation below a critical surface density in disks.
Defined in: function:kennicuttSchmidtConstructorParameters
File: star_formation.rate_surface_density.disks.Kennicutt-Schmidt.F90
Used by:

Name: type
Type: string 1
Description: The metadata type.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: unitLengthInSI
Type: float 0..1
Description: The length unit expressed in the SI system.
Defined in: function:gadgetHDF5ConstructorParameters

File: nBody.import.GadgetHDF5.F90
Used by:

Name: unitMassInSI
Type: float 0..1
Description: The mass unit expressed in the SI system.
Defined in: function:gadgetHDF5ConstructorParameters
File: nBody.import.GadgetHDF5.F90
Used by:

Name: unitVector1
Type: real 0..1
Description: The first (radial) unit vector defining the lightcone geometry.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: unitVector2
Type: real 0..1
Description: The second (angular) unit vector defining the lightcone geometry.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: unitVector3
Type: real 0..1
Description: The third (angular) unit vector defining the lightcone geometry.
Defined in: function:squareConstructorParameters
File: geometry.lightcones.square.F90
Used by:

Name: unitVelocityInSI
Type: float 0..1
Description: The velocity unit expressed in the SI system.
Defined in: function:gadgetHDF5ConstructorParameters
File: nBody.import.GadgetHDF5.F90
Used by:

Name: unitsInSI
Type: float 1
Description: The velocity unit in the SI system.
Defined in: function:mergerTreeFileBuilderConstructorParameters
File: tasks.merger_tree_file_builder.F90
Used by:

Name: untemperedStepCount
Type: integer 1
Default value: 10
Description: The number of untempered steps to take.

Defined in: function:temperedDifferentialEvolutionConstructorParameters
File: posterior_sampling.simulation.tempered_differential_evolution.F90
Used by:

Name: updateCount
Type: real 1
Description: The number of steps between potential updates of the temperature exponent.
Defined in: function:adaptiveConstructorParameters
File: posterior_sampling.differential_proposal_size.temperature_exponent.adaptive.F90
Used by:

Name: useFittingFunction
Type: boolean 1
Default value: .true.
Description: Specifies whether the warm dark matter critical overdensity mass scaling should be computed from a fitting function or from tabulated data.
Defined in: function:barkana2001WDMConstructorParameters
File: structure_formation.critical_overdensity.warm_dark_matter.F90
Used by:

Name: useFormationHalo
Type: boolean 1
Default value: .false.
Description: Specifies whether or not the "formation halo" should be used when solving for the radii of galaxies.
Defined in: function:simpleConstructorParameters
File: galactic_structure.radius_solver.simple.F90
Used by:

Name: useFormationNode
Type: real 1
Default value: .false.
Description: Specifies whether to use the virial velocity of the formation node or current node in the cooling rate "cut-off" modifier.
Defined in: function:cutOffConstructorParameters
File: cooling.cooling_rate.cut_off.F90
Used by:

Name: useInteriorMean
Type: boolean 1
Default value: .false.
Description: Specifies whether to use the specific angular momentum at the cooling radius, or the mean specific angular momentum interior to that radius.
Defined in: function:constantRotationConstructorParameters
File: cooling.specific_angular_momentum.constant_rotation.F90
Used by:

Name: useMeanConcentration
Type: string 1

Default value: .false.
Description: If true, then when computing dark matter profile scale radii using concentrations do not account for any possible scatter in the concentration-mass relation.
Defined in: function:concentrationConstructorParameters
File: dark_matter_profiles.structure.scale.concentration.F90
Used by:

Name: useOneNodeTrees
Type: boolean 0..1
Default value: .false.
Description: If true, trees only consisting of their base node will be augmented.
Defined in: function:augmentConstructorParameters
File: merger_trees.operators.augment.F90
Used by:

Name: useSurveyLimits
Type: boolean 1
Default value: .false.
Description: Specifies whether the limiting redshifts for integrating over the halo mass function should be limited by those of a galaxy survey.
Defined in: function:conditionalMassFunctionConstructorParameters
File: tasks.conditional_mass_function.F90
Used by:

Name: useVelocityMostBound
Type: boolean 0..1
Default value: .false.
Description: If true, the velocity of the most bound particle in velocity space is used as the representative velocity of the satellite. If false, use the mass weighted mean velocity (center-of-mass velocity) of self-bounf particles instead.
Defined in: function:selfBoundConstructorParameters
File: nBody.operator.self_bound.F90
Used by:

Name: variance
Type: real 1
Description: The variance of the normal distribution.
Defined in: function:normalConstructorParameters
File: statistics.distributions.normal.F90
Used by:

Name: varianceBackground
Type: real 1
Description: The variance in the background density field.
Defined in: function:peakBackgroundConstructorParameters
File: statistics.distributions.peak_background.F90
Used by:

Name: vectorRotation

Type: float 1
Default value: [acos(2.0d0*randomSequence%uniformSample()-1.0d0),2.0d0*Pi*randomSequence%uniformSample()] Isotropically random on the unit sphere.
Description: The vector, in spherical coordinates (θ, ϕ), about which the mock catalog should be rotated.
Defined in: function:catalogProjectedCorrelationFunctionConstructorParameters
File: tasks.catalog_projected_correlation_function.F90
Used by:

Name: velocityCharacteristic
Type: real 0..1
Default value: 250.0
Description: The velocity scale at which the supernovae (SNe)-driven outflow rate equals the star formation rate in disks.
Defined in: function:powerLawConstructorParameters
File: star_formation.feedback.disks.power_law.F90
Used by:

Name: velocityCoefficient
Type: real 1
Default value: 0.5
Description: Velocity parameter.
Defined in: function:particleSwarmConstructorParameters
File: posterior_sampling.simulation.particle_swarm.F90
Used by:

Name: velocityCutOff
Type: real 1
Default value: 200.0
Description: The halo maximum velocity scale appearing in the exponential term for cooling timescale in the velocity maximum scaling cooling rate model.
Defined in: function:velocityMaximumScalingConstructorParameters
File: cooling.cooling_rate.velocity_maximum_scaling.F90
Used by:

Name: velocityCutOffExponentRedshift
Type: real 1
Default value: 0.0
Description: The exponent of $(1+z)$ in the velocity scale appearing in the exponential term for cooling timescale in the velocity maximum scaling cooling rate model.
Defined in: function:velocityMaximumScalingConstructorParameters
File: cooling.cooling_rate.velocity_maximum_scaling.F90
Used by:

Name: velocityDispersionDiskGas
Type: real 1
Default value: 10.0 [Leroy et al., 2008]
Description: The velocity dispersion of gas in disks.
Defined in: function:kennicuttSchmidtConstructorParameters

File: star_formation.rate_surface_density.disks.Kennicutt-Schmidt.F90
Used by:

Name: velocityExponent
Type: real 1
Default value: 0.0
Description: The exponent of maximum circular velocity in the velocity maximum scaling model for outflow reincorporation.
Defined in: function:velocityMaximumScalingConstructorParameters
File: hot_halo.outflow_reincorporation.velocity_maximum_scaling.F90
Used by:

Name: velocityRadial
Type: real 1
Default value: -0.90d0
Description: The radial velocity (in units of the host virial velocity) to used for the fixed virial orbits distribution. Default value matches approximate peak in the distribution of Benson [2005].
Defined in: function:fixedConstructorParameters
File: satellites.merging.virial_orbits.fixed.F90
Used by:

Name: velocitySuppressionReionization
Type: real 1
Default value: 35.0
Description: The velocity scale below which baryonic accretion is suppressed.
Defined in: function:simpleConstructorParameters
File: accretion.halo.simple.F90
Used by:

Name: velocityTangential
Type: real 1
Default value: 0.75
Description: The tangential velocity (in units of the host virial velocity) to used for the fixed virial orbits distribution. Default value matches approximate peak in the distribution of Benson [2005].
Defined in: function:fixedConstructorParameters
File: satellites.merging.virial_orbits.fixed.F90
Used by:

Name: verbosityLevel
Type: integer 1
Default value: 1
Description: The level of verbosity for Galacticus (higher values give more verbosity).
Defined in: subroutine:Galacticus_Verbosity_Set_From_Parameters
File: galacticus.display.verbosity.F90
Used by:

Name: virialRadius
Type: real 1
Default value: 1.0

Description: The virial radius of the NFW profile.
Defined in: function:nfwConstructorParameters
File: mass_distributions.spherical.NFW.F90
Used by:

Name: viscosityAlpha
Type: real 1
Default value: 0.1
Description: The value for the viscosity parameter α in an ADAF to be used if [adafViscosityOption]=fixed.
Defined in: function:adafConstructorParameters
File: accretion_disks.ADAF.F90
Used by:

Name: viscosityOption
Type: string 1
Default value: var_str('fit')
Description: Controls how the viscosity parameter α in an ADAF is determined. fit will cause α to be computed using the fitting function of Benson and Babul [2009]; fixed will cause α =[adafViscosityFixedAlpha] to be used.
Defined in: function:adafConstructorParameters
File: accretion_disks.ADAF.F90
Used by:

Name: walltimeMaximum
Type: boolean 1
Default value: -1_kind_int8
Description: If set to a positive number, this is the maximum wall time for which forest evolution is allowed to proceed before the task gives up.
Defined in: function:evolveForestsConstructorParameters
File: tasks.evolve_forests.F90
Used by:

Name: wavelengthCountPerDecade
Type: integer 1
Default value: 10
Description: The number of bins per decade of wavelength to use for calculations of the cosmic background radiation.
Defined in: function:intergalacticBackgroundInternalConstructorParameters
File: radiation.intergalactic_background.internal.F90
Used by:

Name: wavelengthExponent
Type: string 0..1
Default value: 0.7
Description: Exponent of wavelength in the optical depth.
Defined in: function:lmnstyStllrChrltFll2000ConstructorParameters
File: nodes.property_extractor.luminosity_stellar.dust.CharlotFall2000.F90
Used by:

Name: `wavelengthMaximum`
Type: real 1
Default value: 100000.0
Description: The maximum wavelength (in units of Å) to use in calculations of the cosmic background radiation.
Defined in: function:intergalacticBackgroundInternalConstructorParameters
File: radiation.intergalactic_background.internal.F90
Used by:

Name: `wavelengthMinimum`
Type: real 1
Default value: 100.0
Description: The minimum wavelength (in units of Å) to use in calculations of the cosmic background radiation.
Defined in: function:intergalacticBackgroundInternalConstructorParameters
File: radiation.intergalactic_background.internal.F90
Used by:

Name: `wavenumberCount`
Type: integer 0..1
Default value: 60_c_size_t
Description: The number of bins in wavenumber to use in computing the correlation function.
Defined in: function:correlationFunctionConstructorParameters
File: galacticus.output.analyses.correlation_function.F90
Used by:

Name: `wavenumberMaximum`
Type: real 1
Default value: 1.0×10^{3}
Description: The maximum wavenumber at which to tabulate power spectra.
Defined in: function:powerSpectraConstructorParameters
File: tasks.power_spectrum.F90
Used by:

Name: `wavenumberMinimum`
Type: real 1
Default value: 1.0×10^{-3}
Description: The minimum wavenumber at which to tabulate power spectra.
Defined in: function:powerSpectraConstructorParameters
File: tasks.power_spectrum.F90
Used by:

Name: `wavenumberReference`
Type: real 0..1
Default value: 1.0
Description: When a running power spectrum index is used, this is the wavenumber at which the index is equal to `[index]`.
Defined in: function:powerLawConstructorParameters
File: structure_formation.power_spectrum.primordial.power_law.F90

Used by:

Name: `whenCutOff`
Type: real 1
Default value: var_str('after')
Description: Specifies whether cooling is cut off before or after `[redshiftCutOff]`.
Defined in: function:cutOffConstructorParameters
File: cooling.cooling_rate.cut_off.F90
Used by:

Name: `widthBuffer`
Type: float 1
Default value: 30.0
Description: The width of the buffer region around survey geometry to ensure galaxies are not lost when moving to redshift space.
Defined in: function:catalogProjectedCorrelationFunctionConstructorParameters
File: tasks.catalog_projected_correlation_function.F90
Used by:

Name: `widthCutOff`
Type: real 1
Default value: 1.0
Description: The width appearing in the exponential term for cooling timescale in the velocity maximum scaling scaling cooling rate model.
Defined in: function:velocityMaximumScalingConstructorParameters
File: cooling.cooling_rate.velocity_maximum_scaling.F90
Used by:

Name: `widthTransitionStabilityShock`
Type: real 1
Default value: 0.01 [Benson and Bower, 2010]
Description: The width of the transition from stability to instability for cold mode accretion [Benson and Bower, 2010].
Defined in: function:coldModeConstructorParameters
File: accretion.halo.cold_mode.F90
Used by:

Name: `xAxisIsLog`
Type: boolean 0..1
Description: If true, indicates that the x-axis should be logarithmic in a plot of this analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: `xAxisLabel`
Type: string 0..1
Description: A label for the x-axis in a plot of this analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90

Used by:

Name: yAxisIsLog
Type: boolean 0..1
Description: If true, indicates that the y-axis should be logarithmic in a plot of this analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: yAxisLabel
Type: string 0..1
Description: A label for the y-axis in a plot of this analysis.
Defined in: function:volumeFunction1DConstructorParameters
File: galacticus.output.analyses.volume_function_1d.F90
Used by:

Name: zeroPoint
Type: string 1
Description: Mass zero point for the mass function incompleteness surface brightness model, i.e. M_0 in $\mu(M) = \alpha \log_{10}(M/M_0) + \beta$.
Defined in: function:surfaceBrightnessConstructorParameters
File: statistics.mass_function.incompleteness.surface_brightness.F90
Used by:

Name: zeta
Type: real 1
Default value: 0.36
Description: The mass loss scaling with halo mass for the van den Bosch et al. [2005] dark matter halo mass loss rate algorithm.
Defined in: function:vanDenBoschConstructorParameters
File: dark_matter_halos.mass_loss_rates.vanDenBosch.F90
Used by:

Name: accretionDiskSpectraMethod
Attached to: module:Accretion_Disk_Spectra
File: accretion_disks.spectra.F90
Default value: hopkins2007
Description: The method to be used for accretionDiskSpectra.

Name: accretionDisksMethod
Attached to: module:Accretion_Disks
File: accretion_disks.F90
Default value: shakuraSunyaev
Description: The method to be used for accretionDisks.

Name: accretionHaloMethod
Attached to: module:Accretion_Halos
File: accretion.halo.F90
Default value: simple

Description: The method to be used for `accretionHalo`.

Name: `accretionHaloTotalMethod`
Attached to: `module:Accretion_Halo_Totals`
File: `accretion.halo.total.F90`
Default value: simple
Description: The method to be used for `accretionHaloTotal`.

Name: `atomicCrossSectionIonizationPhotoMethod`
Attached to: `module:Atomic_Cross_Sections_Ionization_Photo`
File: `atomic.cross_sections.ionization.photo.F90`
Default value: verner
Description: The method to be used for `atomicCrossSectionIonizationPhoto`.

Name: `atomicExcitationRateCollisionalMethod`
Attached to: `module:Atomic_Rates_Excitation_Collisional`
File: `atomic.rates.excitation.collisional.F90`
Default value: scholzWalters1991
Description: The method to be used for `atomicExcitationRateCollisional`.

Name: `atomicIonizationPotentialMethod`
Attached to: `module:Atomic_Ionization_Potentials`
File: `atomic.ionization_potentials.F90`
Default value: verner
Description: The method to be used for `atomicIonizationPotential`.

Name: `atomicIonizationRateCollisionalMethod`
Attached to: `module:Atomic_Rates_Ionization_Collisional`
File: `atomic.rates.ionization.collisional.F90`
Default value: verner1996
Description: The method to be used for `atomicIonizationRateCollisional`.

Name: `atomicRecombinationRateDielectronicMethod`
Attached to: `module:Atomic_Rates_Recombination_Dielectronic`
File: `atomic.rates.recombination.dielectronic.F90`
Default value: arnaud1985
Description: The method to be used for `atomicRecombinationRateDielectronic`.

Name: `atomicRecombinationRateRadiativeMethod`
Attached to: `module:Atomic_Rates_Recombination_Radiative`
File: `atomic.rates.recombination.radiative.F90`
Default value: verner1996
Description: The method to be used for `atomicRecombinationRateRadiative`.

Name: `blackHoleBinaryInitialSeparationMethod`
Attached to: `module:Black_Hole_Binary_Initial_Separation`
File: `black_holes.binaries.initial_separation.F90`
Default value: spheroidRadiusFraction
Description: The method to be used for `blackHoleBinaryInitialSeparation`.

Name: blackHoleBinaryMergerMethod
Attached to: module:Black_Hole_Binary_Mergers
File: black_holes.binary_mergers.F90
Default value: rezzolla2008
Description: The method to be used for blackHoleBinaryMerger.

Name: blackHoleBinaryRecoilMethod
Attached to: module:Black_Hole_Binary_Recoil_Velocities
File: black_holes.binaries.recoil_velocity.F90
Default value: zero
Description: The method to be used for blackHoleBinaryRecoil.

Name: blackHoleBinarySeparationGrowthRateMethod
Attached to: module:Black_Hole_Binary_Separations
File: black_holes.binaries.separation_growth_rate.F90
Default value: zero
Description: The method to be used for blackHoleBinarySeparationGrowthRate.

Name: chemicalReactionRateMethod
Attached to: module:Chemical_Reaction_Rates
File: chemical.reaction_rates.F90
Default value: zero
Description: The method to be used for chemicalReactionRate.

Name: chemicalStateMethod
Attached to: module:Chemical_States
File: chemical.state.F90
Default value: atomicCIECloudy
Description: The method to be used for chemicalState.

Name: coldModeInfallRateMethod
Attached to: module:Cooling_Cold_Mode_Infall_Rates
File: cooling.cold_mode.infall_rate.F90
Default value: dynamicalTime
Description: The method to be used for coldModeInfallRate.

Name: conditionalMassFunctionMethod
Attached to: module:Conditional_Mass_Functions
File: halo_model.conditional_mass_function.F90
Default value: behroozi2010
Description: The method to be used for conditionalMassFunction.

Name: coolingFunctionMethod
Attached to: module:Cooling_Functions
File: cooling.cooling_function.F90
Default value: atomicCIECloudy
Description: The method to be used for coolingFunction.

Name: coolingInfallRadiusMethod
Attached to: module:Cooling_Infall_Radii
File: cooling.infall_radius.F90
Default value: coolingRadius
Description: The method to be used for coolingInfallRadius.

Name: coolingRadiusMethod
Attached to: module:Cooling_Radii
File: cooling.cooling_radius.F90
Default value: simple
Description: The method to be used for coolingRadius.

Name: coolingRateMethod
Attached to: module:Cooling_Rates
File: cooling.cooling_rate.F90
Default value: whiteFrenk1991
Description: The method to be used for coolingRate.

Name: coolingSpecificAngularMomentumMethod
Attached to: module:Cooling_Specific_Angular_Momenta
File: cooling.specific_angular_momentum.F90
Default value: constantRotation
Description: The method to be used for coolingSpecificAngularMomentum.

Name: coolingTimeAvailableMethod
Attached to: module:Cooling_Times_Available
File: cooling.time_available.F90
Default value: whiteFrenk1991
Description: The method to be used for coolingTimeAvailable.

Name: coolingTimeMethod
Attached to: module:Cooling_Times
File: cooling.cooling_time.F90
Default value: simple
Description: The method to be used for coolingTime.

Name: cosmologicalMassVarianceMethod
Attached to: module:Cosmological_Density_Field
File: structure_formation.cosmological_density_field.F90
Default value: filteredPower
Description: The method to be used for cosmologicalMassVariance.

Name: cosmologyFunctionsMethod
Attached to: module:Cosmology_Functions
File: cosmology.functions.F90
Default value: matterLambda
Description: The method to be used for cosmologyFunctions.

Name: cosmologyParametersMethod

Attached to: module:Cosmology_Parameters
File: cosmology.parameters.F90
Default value: simple
Description: The method to be used for `cosmologyParameters`.

Name: `criticalOverdensityMethod`
Attached to: module:Cosmological_Density_Field
File: structure_formation.cosmological_density_field.F90
Default value: sphericalCollapseMatterLambda
Description: The method to be used for `criticalOverdensity`.

Name: `darkMatterHaloBiasMethod`
Attached to: module:Dark_Matter_Halo_Biases
File: structure_formation.halo_bias.F90
Default value: tinker2010
Description: The method to be used for `darkMatterHaloBias`.

Name: `darkMatterHaloMassAccretionHistoryMethod`
Attached to: module:Dark_Matter_Halo_Mass_Accretion_Histories
File: dark_matter_halos.mass_accretion_history.F90
Default value: wechsler2002
Description: The method to be used for `darkMatterHaloMassAccretionHistory`.

Name: `darkMatterHaloMassLossRateMethod`
Attached to: module:Dark_Matter_Halos_Mass_Loss_Rates
File: dark_matter_halos.mass_loss_rates.F90
Default value: zero
Description: The method to be used for `darkMatterHaloMassLossRate`.

Name: `darkMatterHaloScaleMethod`
Attached to: module:Dark_Matter_Halo_Scales
File: dark_matter_halos.scales.F90
Default value: virialDensityContrastDefinition
Description: The method to be used for `darkMatterHaloScale`.

Name: `darkMatterParticleMethod`
Attached to: module:Dark_Matter_Particles
File: dark_matter.particle.F90
Default value: CDM
Description: The method to be used for `darkMatterParticle`.

Name: `darkMatterProfileConcentrationMethod`
Attached to: module:Dark_Matter_Profiles_Concentration
File: dark_matter_profiles.structure.concentration.F90
Default value: gao2008
Description: The method to be used for `darkMatterProfileConcentration`.

Name: `darkMatterProfileDMOMethod`
Attached to: module:Dark_Matter_Profiles_DMO

File: dark_matter_profiles_DMO.F90
Default value: NFW
Description: The method to be used for darkMatterProfileDMO.

Name: darkMatterProfileHeatingMethod
Attached to: module:Dark_Matter_Profiles_DMO
File: dark_matter_profiles_DMO.F90
Default value: null
Description: The method to be used for darkMatterProfileHeating.

Name: darkMatterProfileMethod
Attached to: module:Dark_Matter_Profiles
File: dark_matter_profiles.F90
Default value: adiabaticGnedin2004
Description: The method to be used for darkMatterProfile.

Name: darkMatterProfileScaleRadiusMethod
Attached to: module:Dark_Matter_Profile_Scales
File: dark_matter_profiles.structure.scale.F90
Default value: concentration
Description: The method to be used for darkMatterProfileScaleRadius.

Name: darkMatterProfileShapeMethod
Attached to: module:Dark_Matter_Profiles_Shape
File: dark_matter_profiles.structure.shape.F90
Default value: gao2008
Description: The method to be used for darkMatterProfileShape.

Name: distributionFunction1DMethod
Attached to: module:Statistics_Distributions
File: statistics.distributions.F90
Default value: uniform
Description: The method to be used for distributionFunction1D.

Name: distributionFunctionDiscrete1DMethod
Attached to: module:Statistics_Distributions_Discrete
File: statistics.distributions.discrete.F90
Default value: binomial
Description: The method to be used for distributionFunctionDiscrete1D.

Name: evolveForestsWorkShareMethod
Attached to: module:Task_Evolve_Forests_Work_Shares
File: tasks.evolve_forests.work_share.F90
Default value: FCFS
Description: The method to be used for evolveForestsWorkShare.

Name: excursionSetBarrierMethod
Attached to: module:Excursion_Sets_Barriers
File: structure_formation.excursion_sets.barrier.F90

Default value: criticalOverdensity
Description: The method to be used for `excursionSetBarrier`.

Name: `excursionSetFirstCrossingMethod`
Attached to: `module:Excursion_Sets_First_Crossings`
File: `structure_formation.excursion_sets.first_crossing_distribution.F90`
Default value: linearBarrier
Description: The method to be used for `excursionSetFirstCrossing`.

Name: `freefallRadiusMethod`
Attached to: `module:Freefall_Radii`
File: `cooling.freefall_radii.F90`
Default value: darkMatterHalo
Description: The method to be used for `freefallRadius`.

Name: `freefallTimeAvailableMethod`
Attached to: `module:Cooling_Freefall_Times_Available`
File: `cooling.freefall_time_available.F90`
Default value: haloFormation
Description: The method to be used for `freefallTimeAvailable`.

Name: `galacticDynamicsBarInstabilityMethod`
Attached to: `module:Galactic_Dynamics_Bar_Instabilities`
File: `galactic_dynamics.bar_instability.F90`
Default value: efstathiou1982
Description: The method to be used for `galacticDynamicsBarInstability`.

Name: `galacticFilterMethod`
Attached to: `module:Galactic_Filters`
File: `galactic.filters.F90`
Default value: always
Description: The method to be used for `galacticFilter`.

Name: `galacticStructureSolverMethod`
Attached to: `module:Galactic_Structure_Solvers`
File: `galactic_structure.radius_solver.F90`
Default value: equilibrium
Description: The method to be used for `galacticStructureSolver`.

Name: `gauntFactorMethod`
Attached to: `module:Atomic_Radiation_Gaunt_Factors`
File: `atomic.radiation.gaunt_factors.F90`
Default value: sutherland1998
Description: The method to be used for `gauntFactor`.

Name: `geometryLightconeMethod`
Attached to: `module:Geometry_Lightcones`
File: `geometry.lightcones.F90`
Default value: square

Description: The method to be used for `geometryLightcone`.

Name: `gravitationalLensingMethod`
Attached to: `module:Gravitational_Lensing`
File: `structure_formation.gravitational_lensing.F90`
Default value: takahashi2011
Description: The method to be used for `gravitationalLensing`.

Name: `haloEnvironmentMethod`
Attached to: `module:Cosmological_Density_Field`
File: `structure_formation.cosmological_density_field.F90`
Default value: uniform
Description: The method to be used for `haloEnvironment`.

Name: `haloMassFunctionMethod`
Attached to: `module:Halo_Mass_Functions`
File: `structure_formation.halo_mass_function.F90`
Default value: tinker2008
Description: The method to be used for `haloMassFunction`.

Name: `haloModelPowerSpectrumModifierMethod`
Attached to: `module:Halo_Model_Power_Spectrum_Modifiers`
File: `halo_model.power_spectrum_modifier.F90`
Default value: identity
Description: The method to be used for `haloModelPowerSpectrumModifier`.

Name: `haloSpinDistributionMethod`
Attached to: `module:Halo_Spin_Distributions`
File: `dark_matter_halos.spins.distributions.F90`
Default value: bett2007
Description: The method to be used for `haloSpinDistribution`.

Name: `hotHaloColdModeCoreRadiiMethod`
Attached to: `module:Hot_Halo_Cold_Mode_Density_Core_Radii`
File: `hot_halo.cold_mode.density_profile.core_radius.F90`
Default value: virialFraction
Description: The method to be used for `hotHaloColdModeCoreRadii`.

Name: `hotHaloMassDistributionCoreRadiusMethod`
Attached to: `module:Hot_Halo_Mass_Distributions_Core_Radii`
File: `hot_halo.mass_distribution.cored.core_radius.F90`
Default value: virialFraction
Description: The method to be used for `hotHaloMassDistributionCoreRadius`.

Name: `hotHaloMassDistributionMethod`
Attached to: `module:Hot_Halo_Mass_Distributions`
File: `hot_halo.mass_distribution.F90`
Default value: betaProfile
Description: The method to be used for `hotHaloMassDistribution`.

Name: hotHaloOutflowReincorporationMethod
Attached to: module:Hot_Halo_Outflows_Reincorporations
File: hot_halo.outflow_reincorporation.F90
Default value: haloDynamicalTime
Description: The method to be used for hotHaloOutflowReincorporation.

Name: hotHaloRamPressureForceMethod
Attached to: module:Hot_Halo_Ram_Pressure_Forces
File: hot_halo.ram_pressure_force.F90
Default value: font2008
Description: The method to be used for hotHaloRamPressureForce.

Name: hotHaloRamPressureStrippingMethod
Attached to: module:Hot_Halo_Ram_Pressure_Stripping
File: hot_halo.ram_pressure_stripping.F90
Default value: font2008
Description: The method to be used for hotHaloRamPressureStripping.

Name: hotHaloRamPressureTimescaleMethod
Attached to: module:Hot_Halo_Ram_Pressure_Stripping_Timescales
File: hot_halo.ram_pressure_stripping.timescale.F90
Default value: ramPressureAcceleration
Description: The method to be used for hotHaloRamPressureTimescale.

Name: hotHaloTemperatureProfileMethod
Attached to: module:Hot_Halo_Temperature_Profiles
File: hot_halo.temperature_profile.F90
Default value: virial
Description: The method to be used for hotHaloTemperatureProfile.

Name: initialMassFunctionMethod
Attached to: module:Stellar_Populations_Initial_Mass_Functions
File: stellar_populations.initial_mass_functions.F90
Default value: chabrier2001
Description: The method to be used for initialMassFunction.

Name: intergalacticMediumFilteringMassMethod
Attached to: module:Intergalactic_Medium_Filtering_Masses
File: intergalactic_medium.filtering_mass.F90
Default value: gnedin2000
Description: The method to be used for intergalacticMediumFilteringMass.

Name: intergalacticMediumStateMethod
Attached to: module:Intergalactic_Medium_State
File: intergalactic_medium.state.F90
Default value: recFast
Description: The method to be used for intergalacticMediumState.

Name: linearGrowthMethod
Attached to: module:Linear_Growth
File: structure_formation.linear_growth.F90
Default value: simple
Description: The method to be used for linearGrowth.

Name: massDistributionMethod
Attached to: module:Mass_Distributions
File: mass_distributions.F90
Default value: none
Description: The method to be used for massDistribution.

Name: massFunctionIncompletenessMethod
Attached to: module:Mass_Function_Incompletenesses
File: statistics.mass_function.incompleteness.F90
Default value: complete
Description: The method to be used for massFunctionIncompleteness.

Name: mergerMassMovementsMethod
Attached to: module:Satellite_Merging_Mass_Movements
File: satellites.merging.mass_movements.F90
Default value: simple
Description: The method to be used for mergerMassMovements.

Name: mergerProgenitorPropertiesMethod
Attached to: module:Satellite_Merging_Progenitor_Properties
File: satellites.merging.progenitor_properties.F90
Default value: standard
Description: The method to be used for mergerProgenitorProperties.

Name: mergerRemnantSizeMethod
Attached to: module:Satellite_Merging_Remnant_Sizes
File: satellites.merging.remnant_sizes.F90
Default value: covington2008
Description: The method to be used for mergerRemnantSize.

Name: mergerTreeBranchingProbabilityMethod
Attached to: module:Merger_Tree_Branching
File: merger_trees.branching_probability.F90
Default value: parkinsonColeHelly
Description: The method to be used for mergerTreeBranchingProbability.

Name: mergerTreeBranchingProbabilityModifierMethod
Attached to: module:Merger_Tree_Branching_Modifiers
File: merger_trees.branching_probability.modifier.F90
Default value: identity
Description: The method to be used for mergerTreeBranchingProbabilityModifier.

Name: mergerTreeBuildMassDistributionMethod

Attached to: module:Merger_Trees_Build_Masses_Distributions
File: merger_trees.construct.build.masses.distribution.F90
Default value: haloMassFunction
Description: The method to be used for mergerTreeBuildMassDistribution.

Name: mergerTreeBuildMassesMethod
Attached to: module:Merger_Trees_Build_Masses
File: merger_trees.construct.build.masses.F90
Default value: sampledDistributionUniform
Description: The method to be used for mergerTreeBuildMasses.

Name: mergerTreeBuilderMethod
Attached to: module:Merger_Trees_Builders
File: merger_trees.construct.builder.F90
Default value: cole2000
Description: The method to be used for mergerTreeBuilder.

Name: mergerTreeConstructorMethod
Attached to: module:Merger_Tree_Construction
File: merger_trees.construct.F90
Default value: build
Description: The method to be used for mergerTreeConstructor.

Name: mergerTreeEvolveTimestepMethod
Attached to: module:Merger_Tree_Timesteps
File: merger_trees.evolve.timesteps.F90
Default value: standard
Description: The method to be used for mergerTreeEvolveTimestep.

Name: mergerTreeEvolverMethod
Attached to: module:Merger_Trees_Evolve
File: merger_trees.evolver.F90
Default value: standard
Description: The method to be used for mergerTreeEvolver.

Name: mergerTreeImporterMethod
Attached to: module:Merger_Tree_Read_Importers
File: merger_trees.construct.read.importer.F90
Default value: galacticus
Description: The method to be used for mergerTreeImporter.

Name: mergerTreeMassResolutionMethod
Attached to: module:Merger_Trees_Build_Mass_Resolution
File: merger_trees.construct.build.mass_resolution.F90
Default value: fixed
Description: The method to be used for mergerTreeMassResolution.

Name: mergerTreeNodeEvolverMethod
Attached to: module:Merger_Trees_Evolve_Node

File: merger_trees.node_evolver.F90
Default value: standard
Description: The method to be used for mergerTreeNodeEvolver.

Name: mergerTreeNodeMergerMethod
Attached to: module:Merger_Trees_Merge_Node
File: merger_trees.node_merger.F90
Default value: singleLevelHierarchy
Description: The method to be used for mergerTreeNodeMerger.

Name: mergerTreeOperatorMethod
Attached to: module:Merger_Tree_Operators
File: merger_trees.operators.F90
Default value: null
Description: The method to be used for mergerTreeOperator.

Name: mergerTreeOutputterMethod
Attached to: module:Merger_Tree_Outputters
File: merger_trees.outputter.F90
Default value: standard
Description: The method to be used for mergerTreeOutputter.

Name: mergerTreeWalkerMethod
Attached to: module:Merger_Tree_Walkers
File: merger_trees.walkers.F90
Default value: isolatedNodes
Description: The method to be used for mergerTreeWalker.

Name: metaTreeProcessingTimeMethod
Attached to: module:Meta_Tree_Compute_Times
File: meta.tree_processing_times.F90
Default value: file
Description: The method to be used for metaTreeProcessingTime.

Name: modelParameterMethod
Attached to: module:Model_Parameters
File: models.parameters.F90
Default value: active
Description: The method to be used for modelParameter.

Name: nbodyHaloMassErrorMethod
Attached to: module:Statistics_NBody_Halo_Mass_Errors
File: statistics.Nbody.halos.mass_errors.F90
Default value: null
Description: The method to be used for nbodyHaloMassError.

Name: nbodyImporterMethod
Attached to: module:NBody_Importers
File: nBody.import.F90

Default value: gadgetHDF5
Description: The method to be used for `nbodyImporter`.

Name: `nbodyOperatorMethod`
Attached to: `module:NBody_Operators`
File: `nBody.operator.F90`
Default value: null
Description: The method to be used for `nbodyOperator`.

Name: `nodePropertyExtractorMethod`
Attached to: `module:Node_Property_Extractors`
File: `nodes.property_extractor.F90`
Default value: nodeIndices
Description: The method to be used for `nodePropertyExtractor`.

Name: `operatorUnaryMethod`
Attached to: `module:Math_Operators_Unary`
File: `math.operators.unary.F90`
Default value: identity
Description: The method to be used for `operatorUnary`.

Name: `outputAnalysisDistributionNormalizerMethod`
Attached to: `module:Output_Analysis_Distribution_Normalizers`
File: `galacticus.output.analyses.distribution_normalizer.F90`
Default value: identity
Description: The method to be used for `outputAnalysisDistributionNormalizer`.

Name: `outputAnalysisDistributionOperatorMethod`
Attached to: `module:Output_Analysis_Distribution_Operators`
File: `galacticus.output.analyses.distribution_operator.F90`
Default value: identity
Description: The method to be used for `outputAnalysisDistributionOperator`.

Name: `outputAnalysisMethod`
Attached to: `module:Output_Analyses`
File: `galacticus.output.analyses.F90`
Default value: null
Description: The method to be used for `outputAnalysis`.

Name: `outputAnalysisMolecularRatioMethod`
Attached to: `module:Output_Analysis_Molecular_Ratios`
File: `galacticus.output.analyses.molecular_ratio.F90`
Default value: obreschkow2009
Description: The method to be used for `outputAnalysisMolecularRatio`.

Name: `outputAnalysisPropertyOperatorMethod`
Attached to: `module:Output_Analysis_Property_Operators`
File: `galacticus.output.analyses.property_operator.F90`
Default value: identity

Description: The method to be used for `outputAnalysisPropertyOperator`.

Name: `outputAnalysisWeightOperatorMethod`
Attached to: `module:Output_Analysis_Weight_Operators`
File: `galacticus.output.analyses.weight_operator.F90`
Default value: identity
Description: The method to be used for `outputAnalysisWeightOperator`.

Name: `outputTimesMethod`
Attached to: `module:Output_Times`
File: `output.times.F90`
Default value: list
Description: The method to be used for `outputTimes`.

Name: `posteriorSampleConvergenceMethod`
Attached to: `module:Posterior_Sampling_Convergence`
File: `posterior_sampling.convergence.F90`
Default value: gelmanRubin
Description: The method to be used for `posteriorSampleConvergence`.

Name: `posteriorSampleDffrntlEvltnProposalSizeMethod`
Attached to: `module:Posterior_Sample_Differential_Proposal_Size`
File: `posterior_sampling.differential_proposal_size.F90`
Default value: none
Description: The method to be used for `posteriorSampleDffrntlEvltnProposalSize`.

Name: `posteriorSampleDffrntlEvltnPrpslSzTmpExpMethod`
Attached to: `module:Posterior_Sampling_Prop_Size_Temp_Exp`
File: `posterior_sampling.differential_proposal_size.temperature_exponent.F90`
Default value: none
Description: The method to be used for `posteriorSampleDffrntlEvltnPrpslSzTmpExp`.

Name: `posteriorSampleDffrntlEvltnRandomJumpMethod`
Attached to: `module:Posterior_Sample_Differential_Random_Jump`
File: `posterior_sampling.differential_random_jump.F90`
Default value: none
Description: The method to be used for `posteriorSampleDffrntlEvltnRandomJump`.

Name: `posteriorSampleLikelihoodMethod`
Attached to: `module:Models_Likelihoods`
File: `models.likelihoods.F90`
Default value: none
Description: The method to be used for `posteriorSampleLikelihood`.

Name: `posteriorSampleSimulationMethod`
Attached to: `module:Posterior_Sampling_Simulation`
File: `posterior_sampling.simulation.F90`
Default value: differentialEvolution
Description: The method to be used for `posteriorSampleSimulation`.

Name: posteriorSampleStateInitializeMethod
Attached to: module:Posterior_Sampling_State_Initialize
File: posterior_sampling.state.initialize.F90
Default value: priorRandom
Description: The method to be used for posteriorSampleStateInitialize.

Name: posteriorSampleStateMethod
Attached to: module:Posterior_Sampling_State
File: posterior_sampling.state.F90
Default value: simple
Description: The method to be used for posteriorSampleState.

Name: posteriorSampleStoppingCriterionMethod
Attached to: module:Posterior_Sampling_Stopping_Criteria
File: posterior_sampling.stopping_criteria.F90
Default value: never
Description: The method to be used for posteriorSampleStoppingCriterion.

Name: powerSpectrumMethod
Attached to: module:Power_Spectra
File: structure_formation.power_spectrum.F90
Default value: standard
Description: The method to be used for powerSpectrum.

Name: powerSpectrumNonlinearMethod
Attached to: module:Power_Spectra_Nonlinear
File: structure_formation.power_spectrum.nonlinear.F90
Default value: cosmicEmu
Description: The method to be used for powerSpectrumNonlinear.

Name: powerSpectrumPrimordialMethod
Attached to: module:Power_Spectra_Primordial
File: structure_formation.power_spectrum.primordial.F90
Default value: powerLaw
Description: The method to be used for powerSpectrumPrimordial.

Name: powerSpectrumPrimordialTransferredMethod
Attached to: module:Power_Spectra_Primordial_Transferred
File: structure_formation.power_spectrum.primordial.transferred.F90
Default value: simple
Description: The method to be used for powerSpectrumPrimordialTransferred.

Name: powerSpectrumWindowFunctionMethod
Attached to: module:Power_Spectrum_Window_Functions
File: structure_formation.power_spectrum.variance.window_function.F90
Default value: topHat
Description: The method to be used for powerSpectrumWindowFunction.

Name: radiationFieldMethod
Attached to: module:Radiation_Fields
File: radiation.F90
Default value: null
Description: The method to be used for radiationField.

Name: ramPressureStrippingDisksMethod
Attached to: module:Ram_Pressure_Stripping_Mass_Loss_Rate_Disks
File: ram_pressure_stripping.mass_loss_rate.disks.F90
Default value: null
Description: The method to be used for ramPressureStrippingDisks.

Name: ramPressureStrippingSpheroidsMethod
Attached to: module:Ram_Pressure_Stripping_Mass_Loss_Rate_Spheroids
File: ram_pressure_stripping.mass_loss_rate.spheroids.F90
Default value: null
Description: The method to be used for ramPressureStrippingSpheroids.

Name: satelliteDynamicalFrictionMethod
Attached to: module:Satellite_Dynamical_Friction
File: satellites.dynamical_friction.acceleration.F90
Default value: chandrasekhar1943
Description: The method to be used for satelliteDynamicalFriction.

Name: satelliteMergingTimescalesMethod
Attached to: module:Satellite_Merging_Timescales
File: satellites.merging.timescale.F90
Default value: jiang2008
Description: The method to be used for satelliteMergingTimescales.

Name: satelliteOrphanDistributionMethod
Attached to: module:Satellite_Oprhan_Distributions
File: satellites.orphans.distributions.F90
Default value: traceDarkMatter
Description: The method to be used for satelliteOrphanDistribution.

Name: satelliteTidalFieldMethod
Attached to: module:Satellites_Tidal_Fields
File: satellites.tidal_fields.F90
Default value: null
Description: The method to be used for satelliteTidalField.

Name: satelliteTidalHeatingRateMethod
Attached to: module:Satellite_Tidal_Heating
File: satellites.tidal_heating.rate.F90
Default value: zero
Description: The method to be used for satelliteTidalHeatingRate.

Name: satelliteTidalStrippingMethod

Attached to: module:Satellite_Tidal_Stripping
File: satellites.tidal_stripping.rate.F90
Default value: zentner2005
Description: The method to be used for satelliteTidalStripping.

Name: starFormationExpulsiveFeedbackDisksMethod
Attached to: module:Star_Formation_Feedback_Expulsion_Disks
File: star_formation.feedback_expulsion.disks.F90
Default value: zero
Description: The method to be used for starFormationExpulsiveFeedbackDisks.

Name: starFormationExpulsiveFeedbackSpheroidsMethod
Attached to: module:Star_Formation_Feedback_Expulsion_Spheroids
File: star_formation.feedback_expulsion.spheroids.F90
Default value: zero
Description: The method to be used for starFormationExpulsiveFeedbackSpheroids.

Name: starFormationFeedbackDisksMethod
Attached to: module:Star_Formation_Feedback_Disks
File: star_formation.feedback.disks.F90
Default value: powerLaw
Description: The method to be used for starFormationFeedbackDisks.

Name: starFormationFeedbackSpheroidsMethod
Attached to: module:Star_Formation_Feedback_Spheroids
File: star_formation.feedback.spheroids.F90
Default value: powerLaw
Description: The method to be used for starFormationFeedbackSpheroids.

Name: starFormationHistoryMethod
Attached to: module:Star_Formation_Histories
File: star_formation.histories.F90
Default value: null
Description: The method to be used for starFormationHistory.

Name: starFormationRateSurfaceDensityDisksMethod
Attached to: module:Star_Formation_Rate_Surface_Density_Disks
File: star_formation.rate_surface_density.disks.F90
Default value: krumholz2009
Description: The method to be used for starFormationRateSurfaceDensityDisks.

Name: starFormationTimescaleDisksMethod
Attached to: module:Star_Formation_Timescales_Disks
File: star_formation.timescales.disks.F90
Default value: intgrtdSurfaceDensity
Description: The method to be used for starFormationTimescaleDisks.

Name: starFormationTimescaleSpheroidsMethod
Attached to: module:Star_Formation_Timescales_Spheroids

File: star_formation.timescales.spheroids.F90
Default value: dynamicalTime
Description: The method to be used for starFormationTimescaleSpheroids.

Name: stellarAstrophysicsMethod
Attached to: module:Stellar_Astrophysics
File: stellar_astrophysics.F90
Default value: file
Description: The method to be used for stellarAstrophysics.

Name: stellarFeedbackMethod
Attached to: module:Stellar_Feedback
File: stellar_astrophysics.feedback.F90
Default value: standard
Description: The method to be used for stellarFeedback.

Name: stellarPopulationMethod
Attached to: module:Stellar_Populations
File: stellar_populations.F90
Default value: standard
Description: The method to be used for stellarPopulation.

Name: stellarPopulationPropertiesMethod
Attached to: module:Stellar_Population_Properties
File: stellar_populations.properties.F90
Default value: instantaneous
Description: The method to be used for stellarPopulationProperties.

Name: stellarPopulationSelectorMethod
Attached to: module:Stellar_Population_Selectors
File: stellar_populations.selectors.F90
Default value: fixed
Description: The method to be used for stellarPopulationSelector.

Name: stellarPopulationSpectraMethod
Attached to: module:Stellar_Population_Spectra
File: stellar_populations.spectra.F90
Default value: FSPS
Description: The method to be used for stellarPopulationSpectra.

Name: stellarPopulationSpectraPostprocessorBuilderMethod
Attached to: module:Stellar_Population_Spectra_Postprocess
File: stellar_populations.spectra.postprocess.F90
Default value: lookup
Description: The method to be used for stellarPopulationSpectraPostprocessorBuilder.

Name: stellarPopulationSpectraPostprocessorMethod
Attached to: module:Stellar_Population_Spectra_Postprocess
File: stellar_populations.spectra.postprocess.F90

Default value: inoue2014
Description: The method to be used for `stellarPopulationSpectraPostprocessor`.

Name: `stellarSpectraDustAttenuationMethod`
Attached to: `module:Stellar_Spectra_Dust_Attenuations`
File: `stellar_populations.spectra.dust_attenuation.F90`
Default value: zero
Description: The method to be used for `stellarSpectraDustAttenuation`.

Name: `stellarTracksMethod`
Attached to: `module:Stellar_Astrophysics_Tracks`
File: `stellar_astrophysics.tracks.F90`
Default value: file
Description: The method to be used for `stellarTracks`.

Name: `stellarWindsMethod`
Attached to: `module:Stellar_Astrophysics_Winds`
File: `stellar_astrophysics.winds.F90`
Default value: leitherer1992
Description: The method to be used for `stellarWinds`.

Name: `supernovaePopulationIIIMethod`
Attached to: `module:Supernovae_Population_III`
File: `stellar_astrophysics.supernovae_PopulationIII.F90`
Default value: hegerWoosley2002
Description: The method to be used for `supernovaePopulationIII`.

Name: `supernovaeTypeIaMethod`
Attached to: `module:Supernovae_Type_Ia`
File: `stellar_astrophysics.supernovae_type_Ia.F90`
Default value: nagashima2005
Description: The method to be used for `supernovaeTypeIa`.

Name: `surveyGeometryMethod`
Attached to: `module:Geometry_Surveys`
File: `geometry.surveys.F90`
Default value: liWhite2009SDSS
Description: The method to be used for `surveyGeometry`.

Name: `taskMethod`
Attached to: `module:Tasks`
File: `tasks.F90`
Default value: evolveForests
Description: The method to be used for `task`.

Name: `tidalStrippingDisksMethod`
Attached to: `module:Tidal_Stripping_Mass_Loss_Rate_Disks`
File: `tidal_stripping.mass_loss_rate.disks.F90`
Default value: null

Description: The method to be used for `tidalStrippingDisks`.

Name: `tidalStrippingSpheroidsMethod`
Attached to: `module:Tidal_Stripping_Mass_Loss_Rate_Spheroids`
File: `tidal_stripping.mass_loss_rate.spheroids.F90`
Default value: null
Description: The method to be used for `tidalStrippingSpheroids`.

Name: `transferFunctionMethod`
Attached to: `module:Transfer_Functions`
File: `structure_formation.transfer_function.F90`
Default value: eisensteinHu1999
Description: The method to be used for `transferFunction`.

Name: `unevolvedSubhaloMassFunctionMethod`
Attached to: `module:Unevolved_Subhalo_Mass_Functions`
File: `structure_formation.unevolved_subhalo_mass_function.F90`
Default value: giocoli2008
Description: The method to be used for `unevolvedSubhaloMassFunction`.

Name: `universeOperatorMethod`
Attached to: `module:Universe_Operators`
File: `universe.operators.F90`
Default value: identity
Description: The method to be used for `universeOperator`.

Name: `virialDensityContrastMethod`
Attached to: `module:Virial_Density_Contrast`
File: `structure_formation.virial_density_contrast.F90`
Default value: sphericalCollapseMatterLambda
Description: The method to be used for `virialDensityContrast`.

Name: `virialOrbitMethod`
Attached to: `module:Virial_Orbits`
File: `satellites.merging.virial_orbits.F90`
Default value: benson2005
Description: The method to be used for `virialOrbit`.

4. Extracting and Analyzing Results

Galacticus stores its output in an HDF5 file. The contents of this file can be viewed and manipulated using a variety of ways including:

HDFView This is a graphical viewer for exploring the contents of HDF5 files;

HDF5 Command Line Tools A set of tools which can be used to extract data from HDF5 files (`h5dump` and `h5ls` are particularly useful);

C++ and Fortran 90 APIs Allow access to and manipulation of data in HDF5 files;

h5py A Python interface to HDF5 files.

In the remainder of this section the structure of Galacticus HDF5 files is described and a general-purpose Perl module which we use to extract data in a convenient manner is outlined.

4.1. General Structure of Output File

Figure 4.1 shows the structure of a typical Galacticus output file. The various groups and subgroups are described below.

4.1.1. UUID

The UUID (Universally Unique Identifier) is a unique identifier assigned to each Galacticus model that is run. It allows identification of a given model and can be referenced from, for example, an external database.

4.1.2. Build Information

Galacticus automatically stores various information about how it was built in the `Build` group attributes. Currently, included attributes consist of:

`FGSL_library_version` The version number of the FGSL library;

`FoX_library_version` The version number of the FoX library;

`GSL_library_version` The version number of the GSL library;

`HDF5_library_version` The version number of the HDF5 library;

`make_CCOMPILER` The C compiler command used;

`make_CCOMPILER_VERSION` The C compiler version information;

`make_CFLAGS` The flags passed to the C compiler;

`make_CPPCOMPILER` The C++ compiler command used;

```
outputFile.hdf5

 |    |    x-> ...                         Group             [optional]
 |    |    x-> ...                         Group             [optional]
 |    |    x-> mergerTree<treeCount>       Group             [optional]
 |    |    |
```

`make_CPPCOMPILER_VERSION` The C++ compiler version information;

`make_CPPFLAGS` The flags passed to the C++ compiler;

`make_FCCOMPILER` The Fortran compiler command used;

`make_FCCOMPILER_VERSION` The Fortran compiler version information;

`make_FCFLAGS` The flags passed to the Fortran compiler;

`make_FCFLAGS_NOOPT` The flags passed to the Fortran compiler for unoptimized compiles;

`make_MODULETYPE` The Fortran module type identifier string;

`make_PREPROCESSOR` The preprocessor command used.

Additionally, two datasets are included which store details of the Galacticus source changeset. `sourceChangeSetMerge` contains the output of "`hg bundle -t none`", that is, it contains a Mercurial changegroup that incorporates any changes made to the current branch relative to the main Galacticus branch. `sourceChangeSetDiff` contains the output of "`hg diff`", that is, all differences between the source code in the working directory and that which has been committed to Mercurial. Used together, these two datasets allow the precise source code used to run the model to be recovered from the main branch Galacticus source.

4.1.3. Filters

For each broadband filter used in the Galacticus model run an entry is added to the datasets in this group. Currently, two datasets are generated:

`name` The name of each filter used.

`wavelengthEffective` The effective wavelength, $\lambda_{\rm eff}$ (defined as $\lambda_{\rm eff} = \int_0^\infty \lambda R(\lambda) {\rm d}\lambda / \int_0^\infty R(\lambda) {\rm d}\lambda$, where $R(\lambda)$ is the filter response) of the filter in Å.

4.1.4. Parameters

The `Parameters` group contains a record of all parameter values (either input or default) that were used for this Galacticus run. The group contains a long list of attributes, each attribute named for the corresponding parameter and with a single entry giving the value of that parameter. If a parameter has subparameters, a group is created having the same name as the parameter, which will contain attributes corresponding to each subparameter. The `scripts/aux/Extract_Parameter_File.pl` script can be used to extract these parameter values to an XML file suitable for re-input into Galacticus.

4.1.5. Version

The `Version` group contains a record of the Galacticus version used for this model, storing the major and minor version numbers, the revision number and the Mercurial revision and hash (if the code is being maintained using Mercurial, otherwise a value of -1 is entered or the revision and the hash attribute is empty). Additionally, the time at which the model was run is stored and, if the `galacticusConfig.xml` file (see §2.1) is present and contains contact details, the name and e-mail address of the person who ran the model.

4.1.6. globalHistory

The `globalHistory` group stores volume averaged properties of the model universe as a function of time. Currently, the properties stored are:

`historyTime` Cosmic time (in Gyr);

`historyExpansion` Expansion factor;

`historyStarFormationRate` Volume averaged star formation rate (in $M_\odot$/Gyr/Mpc^3).

`historyDiskStarFormationRate` Volume averaged star formation rate in disks (in $M_\odot$/Gyr/Mpc^3).

`historySpheroidStarFormationRate` Volume averaged star formation rate in spheroids (in $M_\odot$/Gyr/Mpc^3).

`historyStellarDensity` Volume averaged stellar mass density (in $M_\odot$/Mpc^3).

`historyDiskStellarDensity` Volume averaged stellar mass density in disks (in $M_\odot$/Mpc^3).

`historySpheroidStellarDensity` Volume averaged stellar mass density in spheroids (in $M_\odot$/Mpc^3).

`historyGasDensity` Volume averaged cooled gas density (in $M_\odot$/Mpc^3).

`historyNodeDensity` Volume averaged resolved node density (in $M_\odot$/Mpc^3).

Dimensionful datasets have a `unitsInSI` attribute which gives their units in the SI system.

4.1.7. Outputs

The `Outputs` group contains one or more sub-groups corresponding to the output times requested from Galacticus. Each sub-group contains the following information:

`outputTime` ***(attribute)*** The cosmic time (in Gyr) at this output;

`outputExpansionFactor` ***(attribute)*** The expansion factor at this output;

`nodeData` A group of node properties as described below.

`mergerTree` **subgroups** ***(optional)*** A set of `mergerTree` groups as described below.

Output is controlled by parameters given within the `mergerTreeOutput` section of the parameter file. Current options are:

`outputMergerTrees` If `true` then each merger tree is output to the relevant sub-group at each output time (see §4.1.7). Otherwise merger trees are not output. [Default: `true`.]

`outputReferences` If `true` then an HDF5 reference dataset is written for each merger tree subgroup (see §4.1.7). [Default: `false`.]

`galacticFilterMethod` A "galactic filter" (see §16.4.1) which is applied to each node in the tree to determine whether or not it should be output. By combinding multiple filters it is possible to construct arbitrarily complex criteria for output. [Default: `always`.]

nodeData group

The `nodeData` group contains all data from nodes in all merger trees. The group consists of a collection of datasets each of which lists a property of all nodes in the trees which exist at the output time. Where relevant, each dataset contains an attribute, `unitsInSI`, which gives the units of the dataset in the SI system.

mergerTree datasets

To allow locating of nodes belonging to a given merger tree in the datasets in the `nodeData` group, the `mergerTreeStartIndex` and `mergerTreeCount` datasets list the starting index of each tree's nodes in the `nodeData` datasets, and the number of nodes belonging to each tree respectively. Additionally, the `mergerTreeWeight` dataset lists the `volumeWeight` property for each tree (see §4.1.7) which gives the weight (in Mpc^{-3}) which should be assigned to this tree (and all nodes in it) to create a volume-averaged sample (see §4.2.1). Finally, the `mergerTreeIndex` dataset gives the index of each tree stored in the `nodeData` datasets.

mergerTree subgroups

These subgroups will be present if the `[mergerTreeOutputReferences]` parameter is set to true. Each `mergerTree` subgroup contains HDF5 references to all data on a single merger tree. The group consists of a collection of scalar references each of which points to the appropriate region of the corresponding dataset in the `nodeData` group. Additionally, the `volumeWeight` attribute of this group gives the weight (in Mpc^{-3}) which should be assigned to this tree (and all nodes in it) to create a volume-averaged sample. (A second attribute, `volumeWeightUnitsInSI`, gives the units of `volumeWeight` in the SI system.)

4.1.8. Optional Outputs

Numerous other quantities can be optionally output. These are documented below:

Redshifts

The redshift corresponding to the time at which a node was last isolated can be output by setting `[outputNodeRedshifts]` to `true`. This quantity will be output as `basicRedshiftLastIsolated`.

Mass Accretion Histories

A mass accretion history (i.e. mass as a function of time) for the main branch in each merger tree can be output by setting `massAccretionHistoryOutput=true`. If requested, a new group `massAccretionHistories` will be made in the Galacticus output file. It will contain groups called `mergerTreeN` where `N` is the merger tree index. Each such group will contain the following three datasets, defined for the main branch of the tree[1]:

`nodeIndex` The index of the node in the tree;

`nodeTime` The time at this point in the tree (in Gyr);

`nodeMass` The mass of the node at this point in the tree (in $M_\odot$). The `nodeMass` property is defined to be the total mass of each node in a merger tree. Therefore, it includes both dark and baryonic mass. Additionally, the mass of a node includes the mass of any satellite nodes that it may contain. The mean density of the node depends on the method selected by the `virialDensityContrastMethod` parameter.

[1] "Main branch" is defined by starting from the root node of a tree and repeatedly stepping back to the most massive progenitor of the branch. This does not necessarily pick out the most massive progenitor at a given time.

Merger Tree Dump

A full dump of merger tree structure by setting `mergerTreeStructureDump=true`. In this case, files will be dumped to the directory specified by `[mergerTreeStructureDumpDirectory]` for each merger tree with final mass between `[mergerTreeStructureDumpMassMinimum]` and `[mergerTreeStructureDumpMassMaximum]`. Each tree is dumped to a file named "`mergerTreeDump:<treeIndex>:1.gv`" in the specified directory in GraphViz format.

Conditional Mass Functions

Setting `[mergerTreeComputeConditionalMassFunction]=true` will cause conditional mass functions to be computed and output to the Galacticus output file in a group named "`conditionalMassFunction`". The mass functions are binned in parent halo mass, and the mass ratio of the progenitor to parent halo. Bins are logarithmically spaced in mass (and mass ratio), with the range and number of bins controlled by the parameters:

- `[mergerTreeComputeConditionalMassFunctionParentMassCount]`;
- `[mergerTreeComputeConditionalMassFunctionParentMassMinimum]`;
- `[mergerTreeComputeConditionalMassFunctionParentMassMaximum]`;
- `[mergerTreeComputeConditionalMassFunctionMassRatioCount]`;
- `[mergerTreeComputeConditionalMassFunctionMassRatioMinimum]`;
- `[mergerTreeComputeConditionalMassFunctionMassRatioMaximum]`.

The resulting parent masses and mass ratios are written to datasets `massParent` and `massRatio` respectively. Parent and progenitor halos are defined at a set of redshifts defined by the arrays `[mergerTreeComputeConditionalMas` and `[mergerTreeComputeConditionalMassFunctionProgenitorRedshifts]`, which are written to datasets `redshiftParent` and `redshiftProgenitor`. The resulting conditional masses functions are written to datasets `conditionalMassFunction` and `conditionalMassFunctionError`.

In addition to standard progenitor mass functions, the progenitor mass function conditioned on progenitor rank (i.e. $1^{\rm st}$ most massive, $2^{\rm nd}$, $\ldots$, $n^{\rm th}$ most massive progenitor) is computed and output to the datasets `primaryProgenitorMassFunction` and `primaryProgenitorMassFunctionError`. The depth (i.e. n) is specifed by `[mergerTreeComputeConditionalMassFunctionPrimaryProgenitorDepth]`.

Finally, the progenitor mass functoin conditioned on recent formation is computed and output to the datasets `formationRateFunction` and `formationRateFunctionError`. To be considered "recently formed" a progenitor must have formed between t and $t(1-\Delta)$ where t is the progenitor time and $\Delta=$`[mergerTreeConditionalMassFunctionFormationRateTimeFraction]`.

Pre-Evolution Merger Trees

Galacticus can output the full structure of merger trees prior to any evolution. Merger tree structure can be requested by setting `mergerTreeStructureOutput=true`. Structures are written to a new group, `mergerTreeStructures`, in the Galacticus output file. This group will contain groups called `mergerTreeN` where `N` is the merger tree index. Each such group will contain the following datasets:

`nodeIndex` The index of the node in the tree;

`childIndex` The index of this node's first child node;

`parentIndex` The index of this node's parent node;

`siblingIndex` The index of this node's sibling node;

`nodeTime` The time at this point in the tree (in Gyr);

`nodeMass` The mass of the node at this point in the tree (in $M_\odot$). The `nodeMass` property is defined to be the total mass of each node in a merger tree. Therefore, it includes both dark and baryonic mass. Additionally, the mass of a node includes the mass of any satellite nodes that it may contain. The mean density of the node depends on the method selected by the `virialDensityContrastMethod` parameter.

Additional, optional, datasets can be added by setting appropriate input parameters. Currently these include:

Virial quantities If `mergerTreeStructureOutputVirialQuantities=true` then two additional datasets are included:

`nodeVirialRadius` The virial radius of the node (in Mpc);

`nodeVirialVelocity` The virial velocity of the node (in km/s);

ark matter scale radii If `mergerTreeStructureOutputDarkMatterScaleRadius=true` then an additional dataset is included:

`darkMatterScaleRadius` The scale radius of this node's dark matter halo profile (in Mpc);

tree final descendent If `outputFinalDescendentIndices=true` then an additional dataset is included:

`finalDescendentIndex` The index of the final descendent that this node will reach in its merger trees;

4.2. Topics in Analysis of GALACTICUS Outputs

4.2.1. Building Volume Limited Samples

The `mergerTreeWeight` property (see §4.1.7) property specifies the weight to be assigned to each merger tree in a model to construct a representative (i.e. volume limited) sample of galaxies. GALACTICUS does not typically generate every merger tree in a fixed volume of the Universe (as an N-body simulation might for example) as it's generally a waste of time to simulate millions of low mass halos and only a small number of high mass halos. The `mergerTreeWeight` factors correct for this sampling. If merger trees are being built, then the `mergerTreeWeight`, w_i, for each tree of mass M_i (where the trees are ranked in order of increasing mass) is given by

$$w_i = \int_{M_{\rm min}}^{M_{\rm max}} n(M) {\rm d}M, \tag{4.1}$$

where $n(M)$ is the dark matter halo mass function and

$$M_{\rm min} = \sqrt{M_{i-1} M_i}, \tag{4.2}$$
$$M_{\rm min} = \sqrt{M_i M_{i+1}}. \tag{4.3}$$

Suppose, for example, that we wish to construct a luminosity function of galaxies. In particular, we consider a luminosity bin k which extends from $L_k - \Delta k/2$ to $L_k + \Delta k/2$. If tree i contains N_i galaxies with luminosities $l_{i,j}$, where j runs from 1 to N_i, then the luminosity function in this bin is given by:

$$\phi_k = \sum_i \sum_{j=1}^{N_i} \left\{ \begin{array}{ll} w_i & \hbox{if } L_k - \Delta k/2 < l_{i,j} \leq L_k + \Delta k/2 \\ 0 & \hbox{otherwise.} \end{array} \right. \tag{4.4}$$

4.3. Meta-Analysis of Galacticus

Galacticus contains modules which allow it to analyze and profile its own performance.

4.3.1. Tree Construction/Evolution Timing

The Galacticus_Meta_Tree_Timing module records the time taken to construct and evolve each merger tree. Setting [metaCollectTimingData]=true will cause tree timing data to be recorded and output to the metaData/treeTiming group. Three datasets are written to this group:

treeMasses Gives the base node masses of the recorded trees (in units of $M_\odot$);

treeConstuctTimes Gives the time (in seconds) taken to construct each merger tree;

treeEvolveTimes Gives the time (in seconds) taken to evolve each merger tree.

4.3.2. ODE Evolver Profiler

The Galacticus_Meta_Evolver_Profiler module records statistics on the performance of the main ODE solver used to advance galaxies through time.

Note: Currently, this profiler requires access to features of the GNU Scientific Library that are not implemeted within FGSL. As such, this functionallity is normally *not* compiled with Galacticus. If you want to use the profiler, contact Andrew Benson and request a copy of the modified FGSL source code. Once this is installed, the profiler can be activated by including -DPROFILE in the compilation options (e.g. add this to your GALACTICUS_FCFLAGS environment variable).

When active, setting [profileOdeEvolver]=true will activate profiling. Each step taken by the ODE evolver is then analyzed. First, a record of the size of the time step taken is recorded. Second, the property which is currently limiting the time step size (i.e. that which has the largest error over the step as judged using the same heuristics as the ODE solver uses to determine step size) is determined and a record of this is kept.

At the end of a run the accumulated data is written to the Galacticus output file, into a group named metaData/evolverProfiler. A histogram of time step sizes is written to metaProfileTimeStepCount with bins specified in metaProfileTimeStep—these bins can be adjusted using [metaProfileTimeStepMinimum], [metaProfileTimeStepMaximum] and [metaProfileTimeStepPointsPerDecade]. A histogram of which properties limited step size is written to metaProfilePropertyHitCount with the associated property names written to [metaProfilePropertyNames]. Property names can only be determined if the component to which they belong supports the decodePropertyIdentifiersTask directive (see §16.4.3). Properties which could not be decoded in this way are listed as unknown.

4.4. On-The-Fly Analysis

Galacticus can perform various analyses on-the-fly (i.e. as it is running), outputting the expectation for a particular observed dataset. Analyses are selected by adding the appropriate label to the [mergerTreeAnalyses] parameter (multiple, space-separated labels can be added to this parameter). Available on-the-fly analyses are described below.

On-the-fly analyses exist for several different stellar and gas mass functions. These analyses share several common features which are described below. In general, the model masses are used to construct a mass function by binning into a histogram using the same bins as the observational dataset as the centers of the bins (with bin boundaries placed at the geometric means of consecutive bin centers), and with each galaxy contributing a weight equal to the volume weight of its merger tree. Typically the bins

will be uniformly spaced in the logarithm of mass. Before accumulation to the histogram, galaxy masses are adjusted to account for two effects:

1. *Cosmological parameters:* Typically the observational data will have been analyzed assuming some specific set of cosmological parameters which will differ from that in the current model. Therefore, the mass of the galaxy and the weight assigned to it are both adjusted to match what would be inferred if they were assessed using the same cosmological parameters as were used for the observational data. Typically, this will mean that masses are scaled in proportion to $D_\mathrm{L}^2(\bar{z})$, where $D_\mathrm{L}(z)$ is the luminosity distance to redshift z and $\bar{z}$ is the median redshift of observational sample, while weights are scaled in proportional to $D_\mathrm{c}^2 H^{-1}(z)$, where $D_\mathrm{c}(z)$ is the comoving distance to redshift z and $H(z)$ is the Hubble parameter at redshift z. These scalings are typical for galaxies where masses are determined from luminosities, but may vary in other cases.

2. *Systematic errors:* Each mass function allows for a systematic shift in model masses (to account for systematic uncertainties in the observational analysis) using a simple model. Specifically, model masses are mapped by this model as follows

$$\log_{10} M \rightarrow \log_{10} M + \sum_{i=0}^{N} \alpha_i \log_{10}^i (M/M_0), \tag{4.5}$$

   where M_0 is a mass scale defined for each analysis, N is fixed integer for each analysis, and the coefficients α_i are input parameters `[<label>MassSystematic<i>]`, where `<label>` is the label of the analysis and `<i>` is an integer in the range $0 \ldots N$.

Individual analyses may defined additional transformations of the galaxy mass. These are detailed below.

When the weight of each galaxy is accumulated to the mass function histogram, the logarithm of the galaxy mass is modeled as a Gaussian kernel with width specified by each analysis to account for random errors in the observations and/or scatter in model masses. That is, the weight of each galaxy is spread over every bin of the histogram using this Gaussian kernel. Additionally, if `[analysisMassFunctionsApplyGravitationalLensing` then the mass of each galaxy is convolved with the magnification distribution expected due to gravitational lensing from large-scale structure (see §12.19).

The contribution to the mass function from each model output redshift is computed from the volume associated with that output redshift, given the angular geometry and depth of the survey as determined from the appropriate survey geometry (see §12.59) and assuming that each output redshift represents a range of redshifts running between the geometric means of the times corresponding to each output redshift.

In addition to the mass function, the covariance matrix, $\mathbf{C}_\mathrm{model}$, of the mass function is also computed. The assumptions used when constructing the covariance matrix are controlled by the parameter `[analysisMassFunctionCovarianceModel]`. If set to `binomial`, them to construct $\mathbf{C}_\mathrm{model}$ we make use of the fact that Galacticus works by sampling a set of tree "root masses" from the $z = 0$ dark matter halo mass function. From each root, a tree is grown, within which the physics of galaxy formation is then solved. Root masses are sampled uniformly from the halo mass function. That is, the cumulative halo mass function, $N(M)$, is constructed between the maximum and minimum halo masses to be simulated. The number of root masses, N_r, to be used in a model evaluation is then determined. Root masses are then chosen such that

$$N(M_i) = N(M_\mathrm{min}) \frac{i-1}{N_\mathrm{r}-1} \tag{4.6}$$

for $i = 1 \ldots N_\mathrm{r}$ (noting that $N(M_\mathrm{max}) = 0$ by construction).

Consider first those galaxies which form in the main branch of each tree (i.e. those galaxies which are destined to become the central galaxy of the $z = 0$ halo). Suppose that we simulate N_k halos of root mass M_k at $z = 0$. In such halos the main branch galaxies will, at any time, have stellar masses drawn

from some distribution $p_k(M_\star|t)$. The number of such galaxies contributing to bin i of the mass function is therefore binomially distributed with success probability $p_{ik} = \int_{M_{i,min}}^{M_{i,max}} p_k(M_\star|t)\mathrm{d}M_\star$ and a sample size of N_k. The contribution to the covariance matrix from these main branch galaxies is therefore:

$$\mathcal{C}_{ij} = \begin{cases} p_{ik}(1-p_{ik})N_k w_k^2 & \text{if } i = j \\ -p_{ik}p_{jk}N_k w_k^2 & \text{otherwise,} \end{cases} \tag{4.7}$$

where w_k is the weight to be assigned to each tree. To compute this covariance requires knowledge of the probabilities, p_{ik}. We estimate these directly from the model. To do this, we bin trees into narrow bins of root mass and assume that p_{ik} does not vary significantly across the mass range of each bin. Using all realizations of trees that fall within a given bin, k, we can directly estimate p_{ik}. In computing p_{ik}, the range of halo masses considered and the fineness of binning in halo mass are determined by the parameters `[analysisMassFunctionsHaloMassMinimum]`, `[analysisMassFunctionsHaloMassMaximum]`, and `[analysisMassFunctionsHaloMassBinsPerDecade]`.

If instead, `[analysisMassFunctionCovarianceModel]`=`Poisson`, the main branch galaxies are modeled as being sampled from a Poisson distribution (and so off-diagonal terms in the covariance matrix will be zero).

In addition to the main branch galaxies, each tree will contain a number of other galaxies (these will be "satellite" galaxies at $z = 0$, but at higher redshifts may still be central galaxies in their own halos). Tests have established that the number of satellites in halos is well described by a Poisson process. Note that, as described above, each galaxy contributes a Gaussian distribution to the mass function due to modelling of random errors in stellar mass determinations. For main branch galaxies this is simply accounted for when accumulating the probabilities, p_{ik}. For satellite galaxies, off-diagonal contributions to the covariance matrix arise as a result, $C_{ij} = w_k f_i f_j$, where f_i is the fraction of the galaxy contributing to bin i of the mass function.

The parameter `[analysisMassFunctionsCorrelationTruncateLevel]` allows off-diagonal elements in the model covariance matrix whose correlation is less than the specified value to be truncated to zero. This helps avoid remove numerical noise from the covariance matrix.

4.4.1. ALFALFA HI Mass Function

This analysis, selected using label `alfalfaHiMassFunctionZ0.00`, computes the model expectation for the HI gas mass function of Martin et al. [2010]. Calculation of the mass function follows the basic methdology outlined above. Model galaxy masses and weights are mapped for differences in cosmological parameters as described above, and the simple systematic mass error model is employed with parameter $N = 1$ and $M_0 = 10^9 M_\odot$.

The analysis assumes that only the total interstellar medium (ISM) mass of each galaxy is available, along with the disk radius (assuming an exponential disk). To infer the HI mass the model of Obreschkow et al. [2009] is used. Specifically, the molecular ratio, $R_{\rm mol} \equiv M_{\rm H_2}/M_{\rm HI}$, is given by:

$$R_{\rm mol} = \left(A_1 R_{\rm mol}^{{\rm c}\,\alpha_1} + A_2 R_{\rm mol}^{{\rm c}\,\alpha_2}\right)^{-1}, \tag{4.8}$$

where the ratio at the disk center is given by

$$R_{\rm mol}^{\rm c} = [K r_{\rm disk}^{-4} M_{\rm gas}(M_{\rm gas} + \langle f_\sigma \rangle M_\star)]^\beta. \tag{4.9}$$

Here, $R_{\rm mol}$ is the mass ratio of H_2 to HI, $M_\star$ is the stellar mass of the disk, $r_{\rm disk}$ is the disk exponential scale length, $\langle f_\sigma \rangle$ is the average ratio of the vertical velocity dispersions of gas to stars, and $K = {\rm G}/(8\pi P_\star)$. The HI mass is then determined from:

$$M_{\rm HI} = X_{\rm H} M_{\rm gas}/(1 + R_{\rm mol}), \tag{4.10}$$

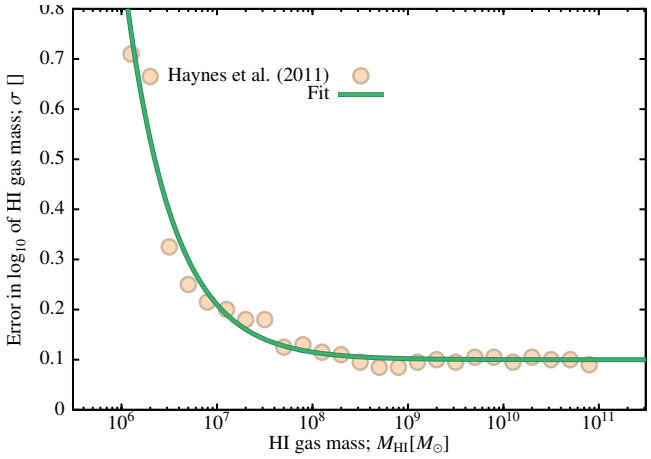

Figure 4.2.: The observational random error in galaxy HI mass as a function of HI mass for the ALFALFA survey. Points show the errors reported by Haynes et al. [2011], while the line shows a simple functional form fit to these errors.

where $X_{\rm H} = 0.778$ is the primordial hydrogen fraction by mass. In the above $K =$ `[alfalfaHiMassFunctionZ0.00MolecularF`
$\langle f_\sigma \rangle =$ `[alfalfaHiMassFunctionZ0.00MolecularFractionfSigma]`, $A_1 =$ `[alfalfaHiMassFunctionZ0.00MolecularFracti`
$A_2 =$ `[alfalfaHiMassFunctionZ0.00MolecularFractionA2]`, $\alpha_1 =$ `[alfalfaHiMassFunctionZ0.00MolecularFractionAlp`
$\alpha_2 =$ `[alfalfaHiMassFunctionZ0.00MolecularFractionAlpha2]`, and $\beta =$ `[alfalfaHiMassFunctionZ0.00MolecularFract`
Default values for these parameters are taken from Obreschkow et al. [2009]. According to Obreschkow (private communication), there remains significant scatter of $\sigma_{R_{\rm mol}} = 0.4$ dex between the predicted $R_{\rm mol}$ from this model and that observed. This is accounted for in when constructing the mass function (see below).

To account for both observational errors and scatter in $R_{\rm mol}$ not captured by the above model, the HI mass of each galaxy is modeled as a Gaussian in $\log_{10} M_{\rm HI}$ when constructing the mass function. Observational random errors on HI mass, including those arising from flux density uncertainties and errors in the assumed distance to each source, are taken from Fig. 19 of Haynes et al. [2011]. The magnitude of the error as a function of HI mass is fit using a functional form:

$$\sigma_{\rm obs} = a + \exp\left(-\frac{\log_{10}(M_{\rm HI}/M_\odot) - b}{c}\right), \tag{4.11}$$

where $\sigma_{\rm obs}$ is the error on $\log_{10}(M_{\rm HI}/M_\odot)$. We find a reasonable fit using values[2] of $a = 0.100 \pm 0.010$, $b = 5.885 \pm 0.100$, and $c = 0.505 \pm 0.020$ as shown in Fig. 4.4.1. The total random error on the logarithm of each galaxy mass is given by $\sigma^2 = \sigma^2_{R_{\rm mol}} + \sigma^2_{\rm obs}$, and is used as the width of the Gaussian kernal when applying each galaxy to the mass function histogram (as described above).

Additionally, HI mass estimates can be affected by HI self-absorption for highly inclined galaxies. [Zwaan et al., 1997, see also Zwaan et al. 2005] estimate that this effect would lead to a mean underestimation of HI masses by a factor 1.1 for a randomly oriented galaxy sample. Therefore, a value of -0.0414 for the systematic parameter `[alfalfaHiMassFunctionZ0.00MassSystematic0]` is recommended.

[2]This should not be regarded as a formal good fit. Error estimates are approximate—we have simply found a functional form that roughly describes them, along with conservative errors on the parameters of this function which are included in the priors.

5. Input Data

In some configurations, Galacticus requires additional input data to run. For example, if asked to process galaxy formation through a set of externally derived merger trees, then a file describing those trees must be given. In the remainder of this section we describe the structure of external datasets which can be inputs to Galacticus.

5.1. Broadband Filters

To compute luminosities through a given filter, Galacticus requires the response function, $R(\lambda)$, of that filter to be defined. Galacticus follows the convention of Hogg et al. [2002] in defining the filter response to be the fraction of incident photons received by the detector at a given wavelength, multiplied by the relative photon response (which will be 1 for a photon-counting detector such as a CCD, or proportional to the photon energy for a bolometer/calorimeter type detector. Filter response files are stored in `data/filters/`. Their structure is shown below, with the `SDSS_g.xml` filter reponse file used as an example:

```
 <filter>
  <description>SDSS g vacuum (filter+CCD +0 air mass)</description>
  <name>SDSS g</name>
  <origin>Michael Blanton</origin>
  <response>
    <datum>   3630.000      0.0000000E+00</datum>
    <datum>   3680.000      2.2690000E-03</datum>
    <datum>   3730.000      5.4120002E-03</datum>
    <datum>   3780.000      9.8719997E-03</datum>
    <datum>   3830.000      2.9449999E-02</datum>
    .
    .
    .
  </response>
  <effectiveWavelength>4727.02994472695</effectiveWavelength>
  <vegaOffset>0.107430167298754</vegaOffset>
</filter>
```

The `description` tag should provide a description of the filter, while the `name` tag provides a shorter name. The `origin` tag should describe from where/whom this filter originated. The `response` element contains a list of `datum` tags each giving a wavelength (in Angstroms) and response pair. The normalization of the response is arbitrary. The `effectiveWavelength` tag gives the mean, response-weighted wavelength of the filter and is used, for example, in dust attenuation calculations. The `vegaOffset` tag gives the value (in magnitudes) which must be added to an AB-system magnitude in this system to place it into the Vega system. Both `effectiveWavelength` and `vegaOffset` can be computed by running

```
scripts/filters/vega_offset_effective_lambda.pl data/filters
```

which will compute these values for any filter files that do not already contain them and append them to the files.

5.2. Merger Trees

While Galacticus can build merger trees using analytic methods it is often useful to be able to utilize merger trees from other sources (e.g. extracted from an N-body simulation). To facilitate this, Galacticus allows merger trees to be read from an HDF5 file[1]. To do so, set the `[mergerTreeConstructMethod]` input parameter to `read` and specify the filename to read via their `[mergerTreeReadFileName]` parameter.

The HDF5 file should follow the general purpose format described in §A. An example of how to construct such a file can be found in the `tests/nBodyMergerTrees` folder. In that folder, the `getMillenniumTrees.pl` script will retrieve a sample of merger trees from the Millennium Simulation database and use the `Merger_Tree_File_Maker.exe` code supplied with Galacticus to convert these into an HDF5 file suitable for reading into Galacticus. The `getMillenniumTrees.pl` script requires you to have a username and password to access the Millennium Simulation database[2]. These can be entered manually or stored in a section of the `galacticusConfig.xml` file (see §2.1) as follows:

```
<millenniumDB>
  <host>
    <name>^myHost$</name>
    <user>myUserName</user>
    <passwordFrom>input</passwordFrom>
    <treePath>/path/to/trees</treePath>
  </host>
  <host>
    <name>default</name>
    <user>myUserName</user>
    <password>myPassword</password>
  </host>
</millenniumDB>
```

Here, each `host` section describes rules for a given computer (with "default" being used if no specific match to the regular expression give in `name` is found). The `user` element gives the user name to use, while the `passwordFrom` element specifies how the password should be obtained. Currently the only allowed mechanism is "input", in which case the password is read from standard input. Alternatively, you can include a `password` element which contains the password itself. Of course, this is insecure...

The optional `treePath` element gives the location where merger trees from the Millennium Simulation can be stored. Some scripts will make use of this location so that Millennium Simulation merger trees can be shared between multiple scripts.

5.2.1. Processing of Merger Tree Files

The "read" merger tree construction method (see §12.32.1) reads these files and processes them into a form suitable for Galacticus to evolve. Merger trees are inherently complex structures, particularly when the possibility of subhalos are considered. Galacticus is currently designed to work with single descendent merger trees, i.e. ones in which the tree structure is entirely defined by specifying which node a given node is physically associated with at a later time. Additionally, Galacticus expects the merger tree file to contain information on the host node, i.e. the node within which a given node is physically

[1] The following assumes that merger trees will be read from a file following Galacticus's standard HDF5 format which is described in §A. Other formats can also be read by selecting the relevant importer via the `[mergerTreeImporterMethod]` parameter.

[2] If you do not have a username and password for the Millennium Simulation database you can request one from contact@g-vo.org.

located. In the following, these two properties are labelled `descendentNode` and `hostNode`. Galacticus assumes that nodes for which `descendentNode`=`hostNode` are isolated halos (i.e. they are their own hosts) while other nodes are subhalos (i.e. they are hosted by some other node). An example of a simple tree structure is shown in Fig. 5.1. The particular structure would be represented by the following list of nodes and node properties (a -1 indicates that no descendent node exists):

node	descendentNode	hostNode
1	-1	1
2	1	2
3	2	3
4	1	4
5	4	5
6	-1	1
7	6	4
8	7	8

The following should be noted when constructing merger tree files:

- Note that Galacticus does not require that nodes be placed on a uniform grid of times/redshifts, nor that mass be conserved along a branch of the tree. After processing the tree in this way, Galacticus builds additional links which identify the child node of each halo and any sibling nodes. These are not required to specify the tree structure but are computationally convenient.
- It is acceptable for a node to begin its existence as a subhalo (i.e. to have never had an isolated node progenitor). Such nodes will be created as satellites in the merger tree and, providing the selected node components (see §11) initialize their properties appropriately, will be evolved correctly.
- It is acceptable for an isolated node to have progenitors, none of which are a primary progenitor. This can happen if all progenitors descend into subhalos in the isolated node. In such cases, Galacticus will create a clone of the isolated node at a very slightly earlier time to act as the primary progenitor. This is necessary to allow the tree to be processed correctly, but does not affect the evolution of the tree.
- Normally, cases where a node's host node cannot be found in the forest will cause Galacticus to exit with an error. Setting `[mergerTreeReadMissingHostsAreFatal]`=`false` will instead circumvent this issue by making any such nodes self-hosting (i.e. they become isolated nodes rather than subhalos). Note that this behavior is not a physically correct way to treat such cases—it is intended only to allow trees to be processed in cases where the full forest is not available.
- It is acceptable for nodes to jump between branches in a tree, or even to jump between branches in different trees. In the latter case, all trees linked by jumping nodes (a so-called "forest" of connected trees) must be stored as a single forest (with multiple root-nodes) in the merger tree file. Galacticus will process this forest of trees simultaneously, allowing to nodes to move between their branches.
- It is acceptable for a subhalo to later become an isolated halo (as can happen due to three-body interactions; see Sales et al. 2007). If `[mergerTreeReadAllowSubhaloPromotions]`=`true` then such cases will be handled correctly (i.e. the subhalo will be promoted back to being an isolated halo). If `[mergerTreeReadAllowSubhaloPromotions]`=`false` then subhalos are not permitted to become isolated halos. In this case, the following logic will be applied to remove all such cases from the tree:

  → For any branch in a tree which at some point is a subhalo:

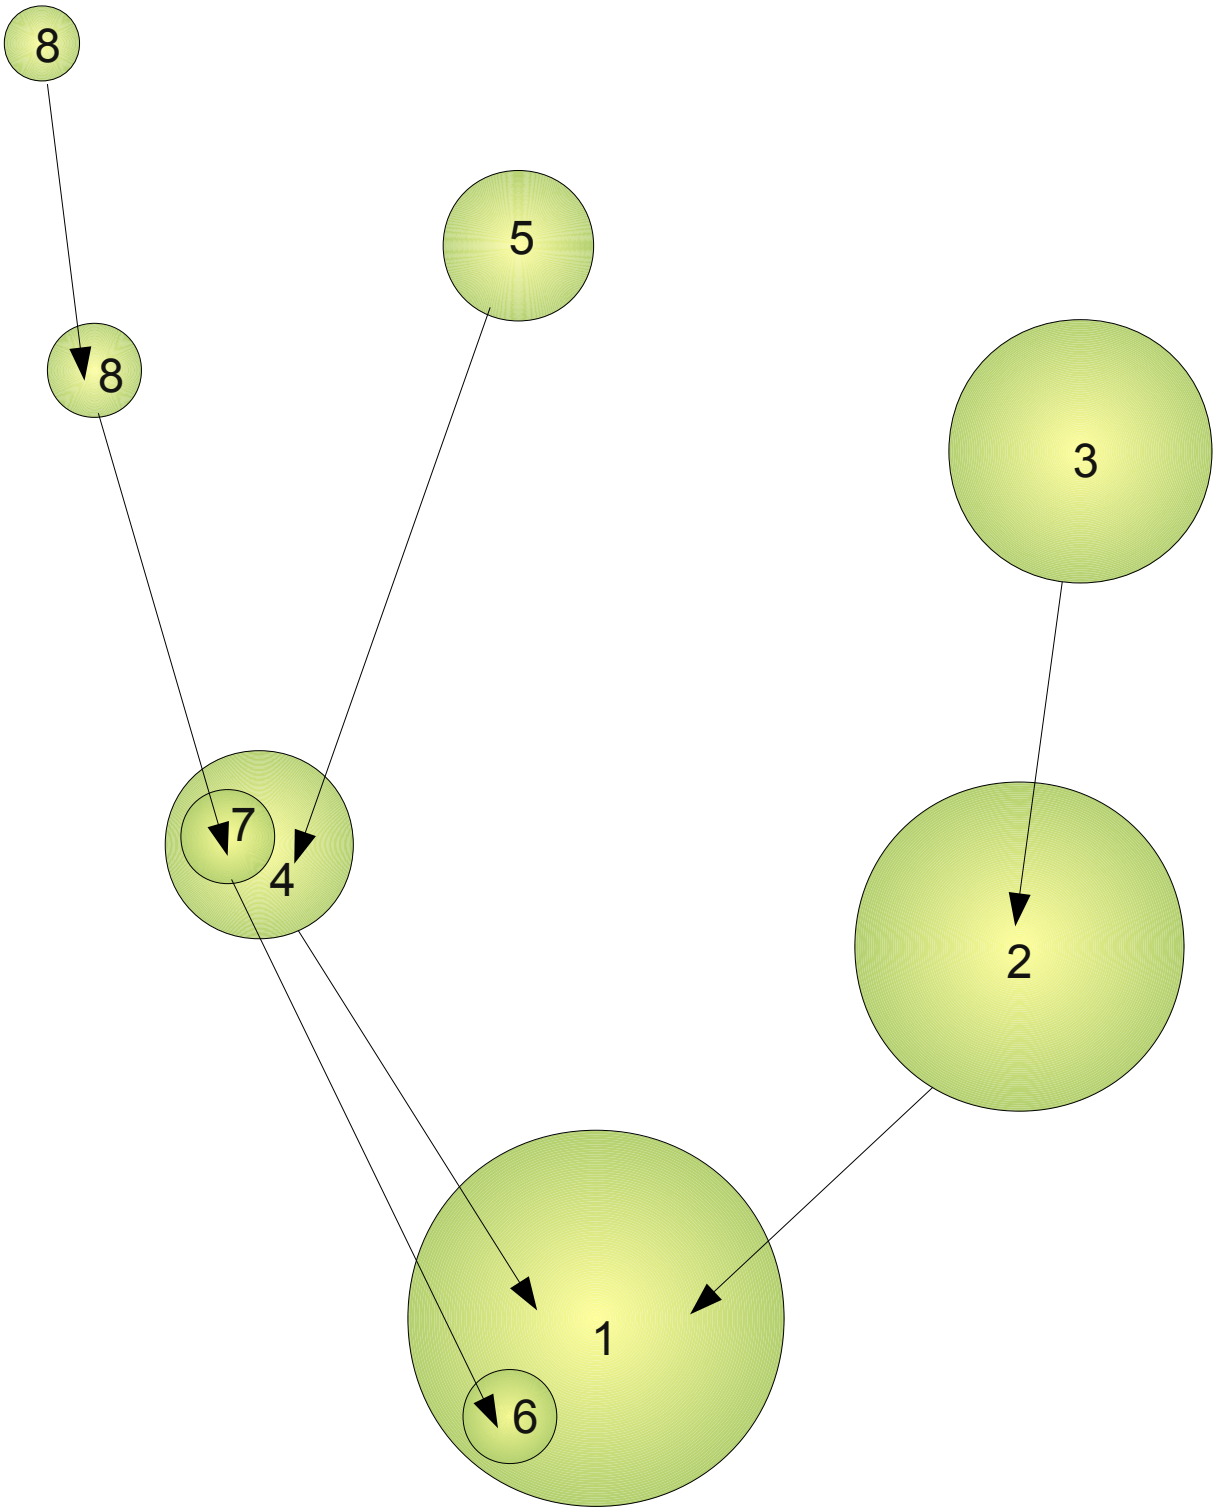

Figure 5.1.: An example of a simple merger tree structure. Colored circles represent nodes in the merger tree. Each node has a unique index indicated by the number inside each circle. Black arrows link each node to its descendent node (as specified by the `descendentNode` property. Where a node is not its own host node it is placed inside its host node.

→ Beginning from the earliest node in the branch that is a subhalo, repeatedly step to the next descendent node;

→ If that descendent is *not* a subhalo then:

→ If there is not currently any non-subhalo node which has the present node as its descendent then current node is only descendent of a subhalo. Therefore, try to make this node a subhalo, and propose the descendent of the host node of the previous node visited in the branch as the new host:

→ If the proposed host exists:

→ If the mass of the current node is less than that of the proposed host:

→ If the proposed hosts exists before the current node, repeatedly step to its descendents until one is found which exists at or after the time of the current node. This is the new proposed host.

→ If the proposed host is a subhalo, make it an isolated node.

→ The current node is made a subhalo within the proposed host.

→ Otherwise:

→ The current node remains an isolated node, while the proposed host is instead made a subhalo within the current node.

→ Otherwise:

→ The proposed host does not exists, which implies the end of a branch has been reached. Therefore, flag the current node as being a subhalo with a host identical to that of the node from which it descended.

Requirements for Galacticus Input Parameters

The following requirements must be met for the input parameters to Galacticus when using merger trees read from file:

- The cosmological parameters (Ω_M, Ω_Λ, Ω_b, H_0, σ_8), if defined in the file, must be set identically in the Galacticus input file unless you set `[mergerTreeReadMismatchIsFatal]=false` in which case you'll just be warned about any mismatch;
- Galacticus assumes by default that all merger trees exist at the final output time—if this is not the case set `[allTreesExistAtFinalTime]=false`.

5.2.2. Setting of Halo Properties

Dark Matter Scale Radii

If `[mergerTreeReadPresetScaleRadii]=true` and the `halfMassRadius` dataset is available within the `haloTrees` group (see §A.7) then the half-mass radii of nodes will be used to compute the corresponding

scale length of the dark matter halo profile[3]. This requires a dark matter profile scale component which supports setting of the scale length (see §11.13).

Satellite Merger Times

If `[mergerTreeReadPresetMergerTimes]=true` then merger times for satellites will be computed directly from the merger tree data read from file. When a subhalo has an isolated halo as a descendent it is assumed to undergo a merger with that isolated halo at that time. Note that this requires a satellite orbit component method which supports setting of merger times (e.g. `[treeNodeMethodSatelliteOrbit]=preset`).

Dark Matter Halo Spins

If `[mergerTreeReadPresetSpins]=true` and the `angularMomentum` dataset is available within the `haloTrees` group (see §A.7) then the spin parameters of nodes will be computed and set. This requires a dark matter halo spin component which supports setting of the spin (see §11.12).

[3]The scale radius is found by seeking a value which gives the correct half mass radius. It is therefore important that the definition of halo mass (specifically the virial overdensity) in Galacticus be the same as was used in computing the input half mass radii.

6. Tutorials

This chapter contains step-by-step guides to performing common tasks with Galacticus.

6.1. Running Galacticus on N-body Merger Trees

See §A.11 for details of how to build merger tree files suitable for input into Galacticus. There are many options which control precisely how merger trees read from file should be handled. The following section provides guidance on the best choice of parameters.

6.1.1. Setting Input Parameters

To utilize merger trees from the file[1] that you created in a Galacticus run it's necessary to set two parameters in the input parameter file that you will use for the run:

```
<!-- Specify that merger trees are to be read from file, and give the name of the file to read -->
<mergerTreeConstructMethod value="read"             />
<mergerTreeReadFileName    value="myNBodyTrees.hdf5"/>
```

The first of these `[mergerTreeConstructMethod]=read` tells Galacticus that merger trees will be constructed by reading them from a file. The second, `[mergerTreeReadFileName]`, gives the name of the file from which to read the trees.

In order to choose sensible settings for the various parameters that control merger trees read from file, it is recommended that you read through each of the items below and follow the guidance given.

Cosmology: In addition to specifying that trees should be read from a file, it's also important to ensure that the values of cosmological parameters in Galacticus match those in the merger tree file. (If they don't match, Galacticus will stop with an error message unless you set `[mergerTreeReadMismatchIsFatal]=false` in which case you'll just be warned about any mismatch.) In our case of using merger trees from the Millennium Simulation, the correct cosmological parameter values can be set as follows:

```
<!-- Use Millennium Simulation cosmology. -->
<cosmologyParametersMethod value="simple"/>
 <HubbleConstant  value="73.0"  />
 <OmegaMatter     value="0.25"  />
 <OmegaDarkEnergy value="0.75"  />
 <OmegaBaryon     value="0.0455"/>
</cosmologyParametersMethod>
<cosmologicalMassVarianceMethod value="filteredPower">
  <sigma_8 value="0.900"/>
</cosmologicalMassVarianceMethod>
<powerSpectrumPrimordialMethod value="powerLaw">
  <index               value="1.000"/>
  <wavenumberReference value="1.000"/>
```

[1] The following assumes that merger trees will be read from a file following Galacticus's standard HDF5 format which is described in Appendix A.

```
    <running              value="0.000"/>
  </powerSpectrumPrimordialMethod>
```

Existance at Final Time: Normally, Galacticus assumes that all merger trees will exist (i.e. have at least one node present) at the final output time. This may not be true of trees extracted from an N-body simulation—in this case Galacticus can be informed of this fact by setting:

```
<allTreesExistAtFinalTime value="false"/>
```

Snapping Nodes to Snapshots: N-body merger trees are often built from "snapshots" of the simulation, i.e. all of the nodes exist at a set of discrete times. Often we want to output nodes at precisely these output times. In such cases it is useful to set:

```
<mergerTreeReadOutputTimeSnapTolerance value="1.0d-3"/>
```

which ensures that the times of nodes are adjusted to lie at precisely the output time if that time is within the specified relative tolerance (this avoids any small differences between node times and output times that can arises due to rounding errors when converting from redshifts to times and vice-versa).

Missing Hosts: Galacticus expects to find each node's host node present in a merger tree forest. If a node's host is not found this is cause for a fatal error to be issued, since it is impossible to correctly construct and evolve the corresponding forest. If you absolutely want to run a forest for which one or more host nodes are missing, you can allow this by setting `[mergerTreeReadMissingHostsAreFatal]=false`—in this case missing host nodes trigger a warning only and nodes without a host are forced to become isolated nodes. This will lead to incorrect tree evolution however, so the recommended setting is:

```
<mergerTreeReadMissingHostsAreFatal value="true"/>
```

Branch Jumps and Subhalo Promotions: If your merger trees contain subhalos they will most likely exhibit two specific behaviors[2]: i) nodes which are subhalos in one timestep may become non-subhalos (isolated halos) in a subsequent timestep ("subhalo promotion"), and ii) nodes which are subhalos in one branch of the tree may "jump" to another branch[3] of the tree becoming a subhalo there ("branch jumping"). These behaviors are fully supported by Galacticus and so we recommend the following settings:

```
<mergerTreeReadAllowSubhaloPromotions value="true"/>
<mergerTreeReadAllowBranchJumps       value="true"/>
```

You may choose to disallow these behaviors by setting either of the above parameters to `false`—for example if you wish to explore how your results would differ if subhalos were forced to remain subhalos forever in their original branch. Note that allowing subhalo promotion while not allowing branch jumping can lead to deadlocks in merger tree evolution, so change these settings with caution.

Note that for trees which do not contain subhalos these two parameters are irrelevant.

Subhalo Masses: If your trees contain subhalos, the mass evolution of those subhalos can be preset in the satellite component of each node. In this way, the subhalo mass in Galacticus will track that specified by the merger tree file. This requires the use of a satellite component which allows presetting of subhalo masses. Recommended settings are therefore:

```
<treeNodeMethodSatellite           value="preset"/>
<mergerTreeReadPresetSubhaloMasses value="true"  />
```

If your trees do not contain subhalos, recommended settings are instead:

[2] These two behaviors are called out as they specifically *do not* occur in merger trees created using Press-Schechter-based algorithms for example.

[3] That is, the subhalo's descendented is hosted by a node other than the descendent of the subhalo's host.

```
<treeNodeMethodSatellite           value="standard"/>
<mergerTreeReadPresetSubhaloMasses value="false"   />
```

Halo Positions/Velocities: If your trees contain position and velocity information for halos, those positions and velocities can be preset in the position component of each node. This requires the use of a position component which allows presetting of positions and velocities. Recommended settings are therefore:

```
<treeNodeMethodPosition        value="preset"/>
<mergerTreeReadPresetPositions value="true"  />
```

If your trees do not contain position information recommended settings are:

```
<treeNodeMethodPosition        value="null" />
<mergerTreeReadPresetPositions value="false"/>
```

Subhalo Orbits: If your trees contain position and velocity information they can be used to preset initial orbit information for subhalos. Note that it is not required that your trees contain subhalos for this orbit presetting to be performed—Galacticus can follow subhalo orbits even if subhalos are not included in the trees themselves. The following settings are recommended:

```
<mergerTreeReadPresetOrbits             value="true"/>
<mergerTreeReadPresetOrbitsSetAll       value="true"/>
<mergerTreeReadPresetOrbitsAssertAllSet value="true"/>
<mergerTreeReadPresetOrbitsBoundOnly    value="true"/>
```

These options will cause an orbit to be preset for each subhalo based on the relative position and velocity of merging halos and assuming that the orbital energy and angular momentum are conserved between the time immediately prior to the merger and the time of virial radius crossing. If the computed orbit does not cross the virial radius of the larger halo or if the computed orbit is unbound, the above options cause an orbit to be preset by drawing orbital parameters at random from the chosen cosmological distribution (see §12.51.2).

Subhalo Merging: If your merger trees contain subhalo information, that information can be used to specify when, and with which other node, each subhalo merges. Specifically, a subhalo is assumed to merge at the time at which it is not the primary progenitor of its descendent halo—possibly with some other delay to be described below. Recommended settings are:

```
<mergerTreeReadPresetMergerTimes          value="true"             />
<mergerTreeReadPresetMergerNodes          value="true"             />
<mergerTreeReadSubresolutionMergingMethod value="boylanKolchin2008"/>
```

The first two options cause subhalos to merge at the time described above, and with their descendent node. The final option accounts for the possibility that the subhalo should not actually merge immediately at this time. For example, in N-body simulations, the subhalo may have simply been lost due to limitations of resolution or halo finder algorithms. The final option specifies that some additional time until merging be added based on the subhalo merging timescale algorithm of Boylan-Kolchin et al. [2008; see §12.51.1], and computed using the last known orbital properties of the subhalo.

Halo Scale Radii: If your merger trees contain information on halo scale radii or half-mass radii, these can be used to preset the scale radius of each node. This requires the use of a dark matter profile component which allows presetting of scale length. Recommended settings are therefore:

```
<mergerTreeReadPresetScaleRadii                  value="true"     />
<mergerTreeReadPresetScaleRadiiFailureIsFatal    value="true"     />
```

```
<mergerTreeReadPresetScaleRadiiConcentrationMinimum value="3"        />
<mergerTreeReadPresetScaleRadiiConcentrationMaximum value="60"       />
<mergerTreeReadPresetScaleRadiiMinimumMass          value="see below"/>
```

Minimum and maximum concentrations are specified—these are used to restrict the range of scale radii that are allowed for a given halo. If scale radii are to be determined based on half-mass radii given in the merger tree file, and if the computed scale radius does not result in a concentration between these limits, then a fatal error is issued.

Finally, you can set a minimum halo mass via the `[mergerTreeReadPresetScaleRadiiMinimumMass]` parameter below which the scale radii or half-mass radii in your file should be considered not reliable. For halos below this mass, scale radii will instead be assigned via the selected dark matter halo concentration method (see §12.11.3).

Halo Angular Momenta: If your merger trees contain spin or angular momentum information these can be preset for each node. Recommended settings are:

```
<treeNodeMethodSpin                   value="preset"/>
<mergerTreeReadPresetSpins            value="true"  />
<mergerTreeReadPresetUnphysicalSpins value="true"  />
```

The last of these options causes any halos for which the spin given in the merger tree file is non-positive to be assigned a spin at random instead, drawn from the specified cosmological distribution (see §12.11.7).

If subhalo masses are not included in their host halo masses in your merger tree file, you should specify how the angular momenta of subhalos should be accounted for when adding their mass to their host halo. If positions and 3D angular momenta are available in your merger tree file, the recommended setting is:

```
<mergerTreeReadSubhaloAngularMomentaMethod value="summation"/>
```

If this information is not present

```
<mergerTreeReadSubhaloAngularMomentaMethod value="scale"    />
```

should be used instead.

If your merger tree file contains 3D spin or angular momentum information, you can choose to make that information available within Galacticus be using the settings:

```
<treeNodeMethodSpin          value="preset3D"/>
<mergerTreeReadPresetSpins3D value="true"    />
```

Subhalo Indices: If your merger trees contain subhalos, you can tell Galacticus to keep track of the indices of subhalos by setting:

```
<treeNodeMethodSatellite            value="preset"/>
<mergerTreeReadPresetSubhaloIndices value="true"  />
```

The Galacticus output file will then contain `satelliteNodeIndex` datasets which list the index (as given in the merger tree file) for all subhalos and halos. Without specifying this presetting, the index of subhalos is frozen at the index of the halo immediately prior to it becomming a subhalo.

The remainder of this section gives more detail about many of the parameters described above and how they affect handling of merger trees read from file. Further parameters can be set to control what information from the stored trees will be used in Galacticus. Examples are given below.

6.1.2. Further Details

Further details of the effects of the many parameters controlling merger trees read from file are given below.

Node Positions

If position and velocity information for tree nodes is available within the merger tree file then Galacticus can be instructed to use this information by using the "preset" method for tree node positions and telling the merger tree construction method to preset node positions as follows:

```
<!-- Use merger tree node positions -->
<treeNodeMethodPosition        value="preset"/>
<mergerTreeReadPresetPositions value="true"  />
```

If position information is unavailable, the "null" position method can be selected and the merger tree construction method instructed not to preset positions as follows:

```
<!-- Do not use merger tree node positions -->
<treeNodeMethodPosition        value="null" />
<mergerTreeReadPresetPositions value="false"/>
```

Virial Orbits

If position and velocity information for tree nodes is available within the merger tree file then Galacticus can be instructed to use this information to estimate the orbit of each subhalo at the point at which it crosses the virial radius of its host halo. This "virial orbit" may then be used by, for example, calculations of merging timescales.

```
<!-- Use merger tree node positions to compute orbits at the virial radius -->
<mergerTreeReadPresetOrbits             value="true"/>
<mergerTreeReadPresetOrbitsBoundOnly    value="true"/>
<mergerTreeReadPresetOrbitsSetAll       value="true"/>
<mergerTreeReadPresetOrbitsAssertAllSet value="true"/>
```

Typically, a merging halo is not seen at precisely the time at which it crosses the virial radius of its host (due to the fact that N-body simulations are output at discretely spaced timesteps). Therefore, Galacticus computes the orbit at the time just prior to merging and assumes that the orbital parameters (energy and angular momentum) remain fixed to propagate the orbit to the virial radius of the host. The second parameter in the above example, `[mergerTreeReadPresetOrbitsBoundOnly]`, specifies whether or not only bound orbits should be set. Some calculations (e.g. of subhalo merging times) assume bound orbits and may fail if given an unbound orbit. Setting this option to `true` causes only bound orbits to be preset—unbound orbits are ignored. Note that some orbits cannot be propagated to the virial radius (i.e. their pericenter is larger than the virial radius). The `[mergerTreeReadPresetOrbitsSetAll]` option, if true, will cause such orbits to be assigned randomly using the selected `[virialOrbitsMethod]`, such that all orbits are assigned. The `[mergerTreeReadPresetOrbitsAssertAllSet]` option requires that all orbits be set—if `[mergerTreeReadPresetOrbitsSetAll]`=`false` and `[mergerTreeReadPresetOrbitsAssertAllSet]`=`true` then Galacticus will exit with an error message if any orbit cannot be set.

If the satellite component additionally permits setting of the satellite position and velocity, these properties will also be assigned based on the relative position and velocity of the satellite and host halos.

Merging Times and Targets

The times at which subhalos merge with their host halo can be determined directly from the merger tree file if subhalo information is included in that file. Merging is assumed to occur when the subhalo no longer has a distinct descendent (i.e. it descends into a non-subhalo). If merging times are to be computed in this way set

```
<treeNodeMethodSatellite         value="preset"/>
<mergerTreeReadPresetMergerTimes value="true"  />
```

which select a satellite orbit method that allows merger times to be present and tell the merger tree construction method to preset those merger times respectively. If merger times are not to be computed in this way then instead set, for example,

```
<treeNodeMethodSatellite         value="standard" />
<mergerTreeReadPresetMergerNodes value="false"    />
<satelliteMergingMethod          value="Jiang2008"/>
```

which selects a standard satellite orbit method, prevents attempts to preset the merger times and selects the `Jiang2008` method for computing merger times instead.

In addition to setting the times of merger events, it is possible to set the target node with which a merging node should merge. By default, Galacticus will assume that all merging occurs with the non-subhalo host node in which a subhalo is located. This may not be the desired behavior when using N-body merger trees. For example, such trees may indicate that a subhalo merges with another subhalo. Setting

```
<mergerTreeReadPresetMergerNodes value="true"/>
```

will cause the target node with which each merger should occur to be determined from the merger tree structure and preset for use in Galacticus.

It is possible to add a delay between the last time at which a subhalo was seen in a simulation and the time at which it is considered to merge. This functionality is motivated by the consideration that a subhalo vanishing from a simulation may be simply due to it dropping below resolution rather than it actually having undergone a merger. The parameter `[mergerTreeReadSubresolutionMergingMethod]` can be used to select a satellite merging timescale method (see §12.51.1) to use in this case. (It is set by default to "`null`" such that no delay before merging occurs.) The orbit of the subhalo around its parent at the last time it is present in the merger tree is passed to this method and used to estimate a time until merging. This delay is added to the time at which the subhalo merges and, if merge target nodes are being set, the target node is updated accordingly.

Subhalo Indices

The indices of subhalos are usually frozen at the index of the halo just prior to becoming a subhalo. The index of the corresponding halo in the original tree (as read from file) can be tracked as follows:

```
<treeNodeMethodSatellite            value="preset"/>
<mergerTreeReadPresetSubhaloIndices value="true"  />
```

to first select the "preset" satellite orbit method (which allows subhalo indices to be preset) and, second, to instruct the merger tree construction algorithm to preset those indices. The index will then be available in output as `satelliteNodeIndex`.

Subhalo Masses

The masses of subhalos (specifically their time evolution after they become subhalos) can be set using the values stored in the merger tree file (if available). To set subhalo masses in this way use

```
<treeNodeMethodSatellite           value="preset"/>
<mergerTreeReadPresetSubhaloMasses value="true"  />
```

to first select the "preset" satellite orbit method (which allows subhalo masses to be preset) and, second, to instruct the merger tree construction algorithm to preset those masses.

Node Spins

If information on the angular momenta of nodes is available in the merger tree file, this can be used to preset the value of the spin parameter in each node[4] by setting:

```
<mergerTreeReadPresetSpins value="true"/>
```

The spin parameter is set using the spin of each node if available, or otherwise using the angular momentum of each node stored in the merger tree file using:

$$\lambda = \frac{|\mathbf{J}||E|^{1/2}}{GM^{5/2}} \tag{6.1}$$

where $|\mathbf{J}|$ is the magnitude of the node's angular momentum, M is the node's mass and E is its energy. Additionally, by setting:

```
<mergerTreeReadPresetSpins3D value="true"/>
```

the spin vector of each node will be set (assuming that the vector spin or angular momenta of nodes are available in the merger tree file) using:

$$\lambda = \frac{\mathbf{J}|E|^{1/2}}{GM^{5/2}}. \tag{6.2}$$

If spins could not be determined for some halos the spin (or angular momentum) should be set to zero in the merger tree file, and the parameter `[mergerTreeReadPresetUnphysicalSpins]` set to `true`. Galacticus will then assign a spin to such halos by sampling from the selected spin distribution (see §12.11.7).

Node Scale Radii

If information on the half-mass or scale radii of nodes is available in the merger tree file, it can be used to preset the value of the dark matter halo scale radius in each node by setting:

```
<mergerTreeReadPresetScaleRadii value="true"/>
```

Before doing this, it is important to be sure that the half-mass or scale radii of the nodes are reliable. For example, in low mass nodes extracted from an N-body simulation resolution effect may limit the accuracy of the measured half-mass or scale radius. In such cases, use the `[mergerTreeReadPresetScaleRadiiMinimumMass]` parameter to specify the lowest mass halos for which the scale radii should be preset—lower mass halos will be assigned a scale radius using the method specified by the `[mergerTreeReadConcentrationFallbackMethod]` parameter (which will default to the value of `[darkMatterConcentrationMethod]`; see §12.11.3). It is also possible to specify minimum and maximum allowed concentrations when computing the scale radius from the half mass radius using the `[mergerTreeReadPresetScaleRadiiConcentrationMinimum]` and `[mergerTreeReadPresetScaleRadiiConcentrationMaximum]` parameters. If matching the half mass radius would require a concentration outside of this range, Galacticus will abort unless `[mergerTreeReadPresetScaleRadiiFa` in which case it will instead silently use the fallback concentration method described above.

If only half-mass radii are available, the scale radius is set by using a root finding algorithm to ensure that half of the total halo mass is enclosed within the specified half-mass radius.

[4] Before doing this, it is important to be sure that the angular momenta of the nodes are reliable. For example, in low mass nodes extracted from an N-body simulation resolution effect may limit the accuracy of the measured angular momentum.

Miscellaneous N-body Properties

Several miscellaneous properties often available from N-body merger trees can also be preset by setting the following parameters to `true`:

mergerTreeReadPresetParticleCounts Sets the number of particles in each halo (requires the `particleCount` dataset to be present in the merger tree file);

mergerTreeReadPresetVelocityMaxima Sets the maxima of halo rotation curves (requires the `velocityMaximum` dataset to be present in the merger tree file);

mergerTreeReadPresetVelocityDispersions Sets the velocity dispersion of halos (requires the `velocityDispersion` dataset to be present in the merger tree file).

Subhalo Promotion

A subhalo may, at a later time, become an isolated halo once again. Galacticus allows you to control whether such behavior is allowed, or should be prohibited. To allow such "subhalo promotion", set:

```
<mergerTreeReadAllowSubhaloPromotions value="true"/>
```

If you choose to inhibit this behavior by setting the above parameter to false, a halo that becomes a subhalo will remain a subhalo forever thereafter. Note that the isolated halo to which it would have been promoted will still exist, and may therefore form its own galaxy. This can result in double counting of mass, and so inhibiting subhalo promotion is not recommended.

"Fly-by" Halos

In some cases, a halo that is part of one tree can later become part of another tree. This can happen in so-called "fly-by" encounters where a halo may briefly become a subhalo in a halo in tree A then leave that halo and become a subhalo in tree B.

The correct way to handle this issue is to combine trees A and B into a single tree (which will now have multiple base nodes). Galacticus will then process these two trees simultaneously, correctly handling the fly-by, and outputting the trees as two separate trees.

If for some reason this is not possible or desired, the fly-by problem will normally cause Galacticus to complain that the host halo of a node cannot be found (since it exists in a different tree). This problem can be avoided by setting:

```
<mergerTreeReadMissingHostsAreFatal value="false"/>
```

In this case, nodes with missing hosts are simply treated as being isolated halos. This will avoid an error condition, but is not a physically correct way to handle such cases, so use with caution.

6.1.3. Using Particles to Track Unresolved Subhalos

In N-body simulations it is possible that a subhalo can become "lost" from the simulation (i.e. can no longer be identified by a halo finder due to resolution issues) before it has actually merged with the central galaxy or been completely tidally destroyed. In such cases it is useful to be able to assign a position to the subhalo at later times. A common approach to assigning a position (and velocity) is to use that of the most bound particle in the subhalo at the last time it was identified. Galacticus allows for particle tracking in this way through the addition of particle information to the merger tree file.

To add particle tracking data to a merger tree file, follow these steps:

1. Identify all subhalos which are lost from the simulation prior to the final timestep;

2. Determine the index of the most bound particle in each such subhalo in the last timestep in which it was identified;

3. For each subhalo, extract the redshift, position, and velocity of that particle (which is usally trivial to do once its index is known) at each subsequent timestep in the simulation;

4. Write these data (along with the particle index) to the `particles` group in the merger tree file as described in §A.10;

5. Add two datasets to the `forestHalos` group:

   a) `particleIndexStart` which should indicate the index in the datasets in the `particles` group at which the data for each halo begins (or -1 if no particle data is included for the halo);

   b) `particleIndexCount` which should indicate the number of entries in the datasets in the `particles` group for each halo (or -0 if no particle data is included for the halo).

6.1.4. Handling of Extremely Large Merger Tree Forests

Halos can move between merger trees (see §6.1.2 and §6.1.2), leading to the necessity of merger tree forests—interconnected groups of merger trees that Galacticus typically processes as a whole. These forests can become very large—in some cases so large that they do not fit within the available memory. Galacticus can handle such forests by splitting them into individual trees. Each tree is processed separately, and nodes are moved between trees as needed. If a tree needs a node from another tree before its evolution can continue, its state can be suspended to disk, and later re-read once the node it requires becomes available. In this way, very large forests can be processed without running out of memory (as trees are stored to disk while they are not being processed).

To cause forests to be split in this way, the following parameters should be set:

```
<treeEvolveSuspendToRAM                   value="false"            />
<treeEvolveSuspendPath                    value="/my/scratch/path/"/>
<mergerTreeReadForestSizeMaximum          value="10000000"         />
<mergerTreeReadSubresolutionMergingMethod value="infinite"         />
```

Here, `treeEvolveSuspendToRAM` specifies that merger trees should be suspended to disk (i.e. not to RAM which is the default), and `treeEvolveSuspendPath` gives a path where the suspended trees can be written—typically scratch space local to the compute node where Galacticus is being run is a good option.

`mergerTreeReadForestSizeMaximum` specifies the maximum number of nodes allowed in a forest before it will be split. A suitable number for this depends on the details of the available RAM, the number of threads sharing that RAM, and the characteristics of the Galacticus model being used (which will affect the memory required per node).

Finally, `mergerTreeReadSubresolutionMergingMethod` is set to `infinite` to prevent any merging (which is not supported for split forests at present, although it should be soon).

6.1.5. Analyzing the Output

Positions and Velocities

Components of the position of each node are output as `positionX`, `positionY` and `positionZ` and can be accessed in the same way as other output properties from Galacticus (see §4.1.7).

Subhalo Masses

The current mass of subhalos is available via the `nodeBoundMass` output dataset and can be accessed in the same way as other output properties from Galacticus (see §4.1.7). For non-subhalos this property is equal to the usual `nodeMass` property.

6.2. Generating Mock Catalogs with Lightcones from the Millennium Simulation

Suppose that you want to create a catalog of galaxies as would be found in a survey of an area of the sky out to some redshift. Such a "mock catalog" can be built by populating with galaxies all of the dark matter halos which happen to lie within the cone which that area makes as it is projected from the observer through the Universe.

Generating such a mock catalog using Galacticus involves first extracting the halos (and their merger trees) within this "lightcone" from a suitable N-body simulation, and then processing them through Galacticus. In this tutorial, we will specifically make use of the Millennium Simulation database to provide the merger trees, but the same principles apply to any N-body simulation.

The script, `scripts/aux/Millennium_Lightcone_Grab.pl` can be used to retrieve merger trees that intersect a given lightcone from the Millennium Database and to store them in Galacticus's format (see §A). The script is used as follows:

```
scripts/aux/Millennium_Lightcone_Grab.pl <lightconeDirectory> <fieldSize> <maximumRedshift>
    --user <myUserName> --password <myPassword> --treesPerFile <treesPerFile>
```

Here, `<lightconeDirectory>` is the name of a (pre-existing) directory into which merger tree data will be stored, `<fieldSize>` is the length (in degrees) of one side of the square field of view of the lightcone, `<maximumRedshift>` is the highist redshift for which halos should be included in the catalog. The `-user` and `-password` options allow you to specify your username and password for accessing the Millennium Simulation database. Finally, the `-treesPerFile` specifies how many merger trees should be stored in each file (the script will split the lightcone between many files—this is primarily so that each request sent to the Millennium Database server is not too large). If no value is specified a default of 200 trees per file will be used.

The script generates multiple SQL queries to the Millennium database in order to first find all halos which intersect the lightcone and second to retrieve the complete merger tree associated with each such halo. These merger trees are then stored in Galacticus's merger tree file format in files named `Lightcone_Trees_AAA:BBB.hdf5` in the given `<lightconeDirectory>`, where `AAA` and `BBB` are numbers giving the first and last trees in the file[5]

Each of the merger tree files created can then be run through Galacticus in the usual way (see §6.1). Outputs should be requested at every Millennium snapshot (up to the largest redshift to be considered), and the `lightcone` filter should be used to cause only those galaxies which intersect the lightcone to be output—for example:

```
<!-- Set output redshifts to the snapshots in the milliMillennium. -->
<outputRedshifts value=
   "0.0000 0.0199 0.0414 0.0645 0.0893 0.1159 0.1444 0.1749 0.2075 0.2425
    0.2798 0.3197 0.3623 0.4079 0.4566 0.5086 0.5642 0.6236 0.6871 0.7550
    0.8277 0.9055 0.9887 1.0779 1.1734 1.2758 1.3857 1.5036 1.6303 1.7663
    1.9126 2.0700 2.2395 2.4220 2.6189 2.8312 3.0604 3.3081 3.5759 3.8657
    4.1795 4.5196 4.8884 5.2888 5.7239 6.1968"
```

[5] Note that these are not the ID numbers of the trees, just a sequential count of all trees retrieved.

```
/>

<!-- Add a lightcone filter with the required geometry -->
<mergerTreeOutput>
  <galacticFilterMethod value="lightcone"/>
</mergerTreeOutput>

<!-- Switch on output of lightcone data -->
<outputLightconeData value="true"/>

<!-- Prune away trees not appearing in the lightcone -->
<mergerTreeOperatorMethod value="pruneLightcone"/>

<!-- Specify lightcone geometry -->
<geometryLightconeMethod value="square">
  <origin value="0 0 0"/>
  <unitVector1 value=" 1 1  1"/>
  <unitVector2 value=" 0 1 -1"/>
  <unitVector3 value="-2 1  1"/>
  <lengthReplication value="500"/>
  <lengthHubbleExponent value="-1"/>
  <lengthUnitsInSI value="3.08567758135e22"/>
  <angularSize value="0.5"/>
  <timeEvolvesAlongLightcone value="true"/>
  <redshift value=
   "0.0000 0.0199 0.0414 0.0645 0.0893 0.1159 0.1444 0.1749 0.2075 0.2425
    0.2798 0.3197 0.3623 0.4079 0.4566 0.5086 0.5642 0.6236 0.6871 0.7550
    0.8277 0.9055 0.9887 1.0779 1.1734 1.2758 1.3857 1.5036 1.6303 1.7663
    1.9126 2.0700 2.2395 2.4220 2.6189 2.8312 3.0604 3.3081 3.5759 3.8657
    4.1795 4.5196 4.8884 5.2888 5.7239 6.1968"
  />
</geometryLightconeMethod>
```

In the above `[outputLightconeData]` causes lightcone coordinate information (i.e. the position and velocity of each galaxy in a coordinate system with axes aligned along the line of sight of the lightcone and parallel to the two edges of the square field of view, along with the redshift) to be output (see §13.9), and `[mergerTreeOperatorMethod]` is set to `pruneLightcone` to cause any merger trees which have no nodes within the lightcone volume to be pruned away (as there is no need to process them). Finally, the `geometryLightconeMethod` parameter describes the geometry of the lightcone to be used—see §16.4.1 for details.

6.3. Using the Instantaneous Recycling Approximation

Choosing `[stellarPopulationPropertiesMethod]=instantaneous` will cause Galacticus to use the instantaneous recycling approximation for all calculations of stellar populations. The recyling rate and yield to use are set by the `[imfNAMERecycledInstantaneous]` and `[imfNAMEYieldInstantaneous]` parameters respectively, where `NAME` is the name of the appropriate IMF.

Setting `[stellarPopulationPropertiesMethod]=noninstantaneous` causes Galacticus to use a fully non-instantaneous, metal-depdendent calculation of recycling, metal production and SNe rates.

However, it is possible to force this method to operate in the instantaneous recycling approximation limit (which can be useful for testing and comparison) by setting:

```
<!-- Force the calculation of recycling, yields etc. to   -->
<!-- be done assuming instantaneous recycling             -->
<starFormationImfInstantaneousApproximation value="true"/>
<!-- Set the mass of stars which should be used as the    -->
<!-- dividing line between long-lived and instantaneously -->
<!-- evolving in this approximation.                      -->
<starFormationImfInstantaneousApproximationMassLongLived value="1.0"/>
<!-- Set the effective age of populations to use in this -->
<!-- approximation when computing SNe numbers.           -->
<starFormationImfInstantaneousApproximationEffectiveAge value="13.8"/>
```

6.4. Postprocessing of Stellar Spectra

Stellar luminosities are computed by convolving a library of simple stellar populations with the star formation history of each galaxy. Galacticus allows the spectra of those simple stellar populations to be postprocessed (after being read from file or internally generated for example) before they are utilized in the convolution integral. This postprocessing can modify the spectra in arbitrary ways that depend on wavelength, redshift, and age of stellar population. Furthermore, Galacticus allows you to chain together stellar spectra postprocessors into a set to allow multiple postprocessings to be applied. Furthermore again, you can define an arbitrary number of sets and apply different sets to different luminosities.

Typical uses of stellar spectra postprocessors include accounting for absorption of galaxy light by the intervening IGM, or capturing only the light from recent star formation[6]. A full list of the available postprocessors can be found in §12.49.

If you don't specify a postprocessing set, the "default" set (consisting of the `inoue2014` postprocessor; see §12.49.1) is applied to each luminosity calculation. To specify other postprocessing sets add the following to your parameter file:

```
<luminosityPostprocessSet value="default recent unabsorbed recentUnabsorbed"/>
```

where one set must be specified for each luminosity specified in the `luminosityFilter` parameter. Note that set names can be reused in order to apply the same postprocessor set to multiple luminosities.

The chain of postprocessors to apply for each set is then specified as follows:

```
<stellarPopulationSpectraPostprocessRecentMethods           value="inoue2014 recent"/>
<stellarPopulationSpectraPostprocessUnabsorbedMethods       value="identity"        />
<stellarPopulationSpectraPostprocessRecentUnabsorbedMethods value="recent"          />
```

In this case we've constructed three new sets, in addition to the default set (which applies just the `inoue2014` postprocessor). The `recent` set applies both the `inoue2014` IGM absorption postprocessor, followed by the `recent` postprocessor to retain only recently emitted light. The `unabsorbed` set ignores IGM absorption entirely—it does this by using the `identity` postprocessor which leaves the spectrum unaffected. Finally, the `recentUnabsorbed` set applies only the `recent` filter while ignoring IGM absorption.

In this way it is relatively easy to extract multiple different measures of luminosity from a Galacticus model. For example, you could construct four postprocessor sets, each corresponding to one of the four different IGM absorption models (`lycSuppress`, `madau1995`, `meiksin2006`, and `inoue2014`) and apply these to the same luminosity filter to assess how luminosity depends on the IGM model used.

[6] Perhaps so that additional dust extinction can be applied to the light of recently formed stars.

6.5. Migrating Parameter Files to a New Version

The names and allowed values of parameters often change between versions of Galacticus. To permit easy and error-free migration between versions a script is provided to translate parameter files from earlier to later versions. To migrate a parameter file simply use:

```
scripts/aux/parametersMigrate.pl parameters.xml newParameters.xml
```

By default, this script will translate from the previous to the current version of Galacticus. If your parameter file contains a `version` element then this will be used to determine which version of Galacticus the parameter file was constructed for. The migration script will then migrate the parameter file through all intermediate versions to bring it into compliance with the current version. You can also specify input and output versions directly:

```
scripts/aux/parametersMigrate.pl parameters.xml newParameters.xml --inputVersion 0.9.0 --outputVersion 0
```

will convert `parameters.xml` from version 0.9.0 syntax to version 0.9.3 syntax.

6.5.1. Reionization Calculations

Galacticus can self-consistently solve for the evolution of the IGM as it becomes photoionized by light emitted by stars and AGN. To activate this calculation, include the following in your parameters file:

```
<!-- IGM evolver -->
<intergalacticMediumStateMethod  value="internal"/>
<igmPropertiesCompute            value="true"    />
<igmPropertiesTimeCountPerDecade value="10"      />

<!-- Background radiation -->
<backgroundRadiationCompute                   value="true"    />
<radiationIntergalacticBackgroundMethod       value="internal"/>
<backgroundRadiationWavelengthCountPerDecade value="50"      />
<backgroundRadiationTimeCountPerDecade        value="10"      />

<!-- Halo accretion options -->
<accretionHaloMethod value="naozBarkana2007"/>
```

The first block of parameters switches Galacticus to using an internal calculation for the state of the IGM, instructs it to solve for IGM properties as a function of time, and specifies that IGM properties should be updated 10 times per decade of cosmic time. Specifically, at each of these time intervals, solving of galaxy evolution is halted and the IGM evolved up to this time using the currently computed photoionizing background spectrum.

The second block of parameters activates an internal calculation of cosmic background radiation, in which the background is computed from the emissivities of model galaxies and AGN. The number of points at which to tabulate the background per decade of wavelength and cosmic time are specified.

Finally, the third block of parameters tells Galacticus to use the Naoz and Barkana [2007] prescription for computing gas accretion into halos from the IGM. This prescription uses the filtering mass to determine accretion rates, and will take the filtering mass from the internal IGM evolution calculation.

With these three sets of configurations, Galacticus will perform a self-consistent evolution of the IGM—in the sense that the IGM is ionized by photons emitted by model galaxies and AGN, while galaxy evolution is affected by the computed state of the model IGM. Note that, when run in this way, Galacticus needs to keep all merger trees in memory simultaneously (as they are run synchronously to allow the IGM properties to evolved alongside galaxy properties).

Once completed, data on the IGM and background radiation are written to the output file in the `igmProperties` and `backgroundRadiation` groups respectively.

7. Troubleshooting

This chapter contains guidance on solving various problems that you might encounter when running Galacticus.

7.1. Low CPU utilization with large numbers of output redshifts

If a Galacticus model is failing to make use of the majority of the available CPU cycles, and you are running a model with a large number of output redshifts the problem may be that I/O to disk is limiting the rate at which merger trees can be processed. I/O occurs through the HDF5 library which provides caching functionality. Therefore, this problem can often be mitigated by expanding the size of the HDF5 library's cache. Galacticus allows you to do this using a set of input parameters:

`[hdf5CacheElementsCount]` HDF5 limits the number of objects that it will store in its cache. Increasing this number will allow more data to be cached and potentially make disk I/O more efficient. We have had good results by setting this number to some factor (e.g. 2) times the product of the number of output redshifts and the number of properties being output in each snapshot.

`[hdf5CacheSizeBytes]` HDF5 also limits the size of the cache in bytes. We have had good results setting this to a factor of a few above the product of `[hdf5CacheElementsCount]`, the chunk size (see below) and the size of each output property (8 bytes).

`[hdf5SieveBufferSize]` HDF5 uses a sieve buffer to speed reading/writing of partial datasets. Increasing the buffer size (specified here in bytes) may improve I/O performance. We have had good results using a value of 512Kb.

`[hdf5UseLatestFormat]` Normally, HDF5 selects an internal file format to used based on maximum portability. If you set this option to `true` HDF5 will instead use the latest format that it supports—typically allowing it to employ optimizations unavailable to older versions of HDF5. Note that this can make the output file unreadable by older versions of the HDF5 library.

Additionally, you can ensure that compression is switched off in the HDF5 output by setting `[hdf5CompressionLevel]`$=-1$. Finally, adjusting the HDF5 chunk size via the `[hdf5ChunkSize]` parameter may make for more efficient I/O. HDF5 datasets are read/written in chunks of this size. Increasing the size may improve I/O performance.

8. Numerical Implementation

8.1. Timestepping Criteria

Galacticus evolves each merger tree forest by repeatedly walking the trees and evolving each node forward in time by some timestep Δt. Nodes are evolved individually such that nodes in different branches of a tree may have reached different cosmic times at any given point in the execution of Galacticus. Each node is evolved over the interval Δt using an adaptive ordinary differential equation (ODE) solver, which adjusts the smaller timesteps, δt, taken in evolving the system of ODEs to maintain a specified precision.

The choice of Δt then depends on other considerations. For example, a node should not be evolved beyond the time at which it is due to merge with another galaxy. Also, we typically don't want satellite nodes to evolve too far ahead of their host node, such that any interactions between satellite and host occur (near) synchronously.

In the remainder of this section we list all criteria used to select Δt for a node. All criteria are considered and the largest Δt consistent with all criteria is selected.

8.1.1. Tree Criteria

The following timestep criteria ensure that tree evolution occurs in a way which correctly preserves tree structure and ordering of interactions between nodes.

"Branch Segment" Criteria

For nodes which are the primary progenitor of their parent, the "branch segment" criterion asserts that

$$\Delta t \leq t_{\rm parent} - t \tag{8.1}$$

where t is current time in the node and $t_{\rm parent}$ is the time of the parent node. This ensures that primary progenitor nodes to not evolve beyond the time at which their parent (which they will replace) exists. If this criterion is the limiting criteria for Δt then the node will be promoted to replace its parent at the end of the timestep.

"Parent" Criteria

For nodes which are satellites in a hosting node the "parent" timestep criterion asserts that

$$\Delta t \leq t_{\rm host}, \tag{8.2}$$
$$\Delta t \leq \epsilon_{\rm host}(a/\dot{a}), \tag{8.3}$$

where $t_{\rm host}$ =`[timestepHostAbsolute]`, $\epsilon_{\rm host}$ =`[timestepHostRelative]`, and a is expansion factor. These criteria are intended to prevent a satellite for evolving too far ahead of the host node before the host is allowed to "catch up".

"Satellite" Criteria

For nodes which host satellite nodes, the "satellite" criterion asserts that

$$\Delta t \leq \min(t_{\rm satellite}) - t, \tag{8.4}$$

where t is the time of the host node and $t_{\rm satellite}$ are the times of all satellite nodes in the host. This criterion prevents a host from evolving ahead of any satellites.

"Sibling" Criteria

For nodes which are primary progenitors, the "sibling" criterion asserts that

$$\Delta t \leq \min(t_{\rm sibling}) - t, \tag{8.5}$$

where t is the time of the host node and $t_{\rm sibling}$ are the times of all siblings of the node. This criterion prevents a node from reaching its parent (and being promoted to replace it) before all of its siblings have reach the parent and have become satellites within it.

"Mergee" Criteria

For nodes with mergee nodes, the "mergee" criterion asserts that

$$\Delta t \leq \min(t_{\rm merge}) - t, \tag{8.6}$$

where t is the time of the host node and $t_{\rm merge}$ are the times at which the mergees will merge. This criterion prevents a node from evolving past the time at which a merger event takes place.

8.1.2. General Criteria

"Simple" Criteria

The `simple` timestep criteria assert that

$$\Delta t \leq t_{\rm simple}, \tag{8.7}$$
$$\Delta t \leq \epsilon_{\rm simple}(a/\dot{a}), \tag{8.8}$$

where $t_{\rm simple}$ =`[timestepSimpleAbsolute]`, $\epsilon_{\rm simple}$ =`[timestepSimpleRelative]`, and a is expansion factor. These criteria are intended to prevent any one node evolving over an excessively large time in one step. In general, these criteria are not necessary, as nodes should be free to evolve as far as possible unless prevented by some physical requirement. These criteria are therefore present to provide a simple example of how timestep criteria work.

"Satellite" Criteria

The `satellite` timestep criteria asserts the following for satellite nodes. If the satellite's merge target has been advanced to at least a time of $t_{\rm required} = t_{\rm satellite} + \Delta t_{\rm merge} - \delta t_{\rm merge,maximum}$ then

$$\Delta t \leq \Delta t_{\rm merge}, \tag{8.9}$$

where $t_{\rm satellite}$ is the current time for the satellite node, $\Delta t_{\rm merge}$ is the time until the satellite is due to merge and $\delta t_{\rm merge,maximum}$ is the maximum allowed time difference between merging galaxies. This ensures that the satellite is not evolved past the time at which it is due to merge. If this criterion is the limiting criteria for Δt then the merging of the satellite will be triggered at the end of the timestep.

If the merge target has not been advanced to at least $t_{\rm required}$ then instead

$$\Delta t \leq \max(\Delta t_{\rm merge} - \delta t_{\rm merge,maximum}/2, 0), \tag{8.10}$$

is asserted to ensure that the satellite does not reach the time of merging until its merge target is sufficiently close (within $\delta t_{\rm merge,maximum}$) of the time of merging.

8.1.3. Output Criteria

"History" Criteria

The `history` timestep criterion asserts that

$$\Delta t \leq t_{{\rm history},i} - t \tag{8.11}$$

where t is the current time, $t_{{\rm history},i}$ is the $i^{\rm th}$ time at which the global history (see §4.1.6) of galaxies is to be output and i is chosen to be the smallest i such that $t_{{\rm history},i} > t$. If there is no i for which $t_{{\rm history},i} > t$ this criterion is not applied. If this criterion is the limiting criterion for Δt then the properties of the galaxy will be accumulated to the global history arrays at the end of the timestep.

"Record Main Branch Evolution" Criteria

If selected, the `recordEvolution` timestep criterion asserts that

$$\Delta t \leq t_{{\rm record},i} - t \tag{8.12}$$

where t is the current time, $t_{{\rm record},i}$ is the $i^{\rm th}$ time at which the evolution of main branch galaxies is to be output and i is chosen to be the smallest i such that $t_{{\rm record},i} > t$. If there is no i for which $t_{{\rm record},i} > t$ this criterion is not applied. If this criterion is the limiting criterion for Δt then the properties of the galaxy will be recorded at the end of the timestep.

Part II.

Advanced Use

9. Constraining Galacticus

9.1. Model Accuracy

The model accuracy script processes the model described by a standard Galacticus constraints configuration file to assess how accurate the model is. Specifically, it determines the relative contribution to the covariance of each constraint arising from the finite number of merger trees run in the model and the intrinsic covariance of the observations. An accurate model should make a negligible contribution to the covariance.

To run the model accuracy script use

```
constraints/testModelAccuracy.pl <configFile>
```

where `configFile` is the name of the configuration file. The script will run the model multiple times, reducing the number of trees per decade by a factor of two each time (this is done 8 times, such that the smallest model run has a factor 128 times fewer trees than the original model). Furthermore, this sequence of models is run for three different choices for sampling halo masses: `powerLaw`, `haloMassFunction`, and `stellarMassFunction` (see §12.11.6).

For each constraint in the specified constraint compilation and accuracy measure is constructed which is the root mean squared ratio of the error arising from the finite number of trees and the intrinsic error of the constraint data.

Accuracy analysis files are written to:

```
<workDirectory>/accuracy
```

For each constraint in the compilation a plot showing accuracy measure as a function of CPU time is written to

```
<constraintLabel>_mergerTreeBuildTreesPerDecade.pdf
```

Each point in the plot is labelled with the number of merger trees per decade. An accurate model should have accuracy measure significantly below unity. This plot is also useful to see which sampling method achieves that accuracy in the least amount of CPU time.

Additionally, a report is written to:

```
<constraintLabel>Report.txt
```

This file lists, for each sampling method, the accuracy measure achieved and the CPU time taken for the largest model run.

9.2. Model Convergence

The model convergence script processes the model described by a standard Galacticus constraints configuration file to assess how well converged the model is with respect to several of Galacticus's numerical parameters. Specifically, it determines the a covariance measure for each constraint in the specified compilation file.

To run the model convergence script use

```
constraints/testConvergnce.pl <configFile>
```

where `configFile` is the name of the configuration file. The script will run the model multiple times, adjusting the value of a numerical parameter each time.

For each constraint in the specified constraint compilation a convergence measure, C, is constructed which

$$C = \sum_i \frac{(y_i - y_{\mathrm{ideal},i})^2}{\sqrt{2}\sigma^2_{\mathrm{ideal},i}} \tag{9.1}$$

where y_i is the result of the constraint, σ_i is the error on the result, and subscript "ideal" refers to the model with the most ideal value (i.e. that in the original, unmodified model) of the numerical parameter being tested (which might be the lowest value for a mass resolution, or the highest value for the maximum tree mass simulated for example). To be converged, the convergence measure should remain consistent with unity within a significant distance[1] away from the ideal value.

Convergence analysis files are written to:

```
<workDirectory>/convergence
```

For each combination of constraint in the compilation and numerical parameter a plot showing the convergence measure as a function of the numerical parameter is created in:

```
<constraintLabel>_<numericalParameter>.pdf
```

Each point in the plot has an error bar since, due to the limited number of merger trees run, the convergence measure is not known with perfect precision. A horizontal line shows the desired convergence measure of unity.

Additionally, a report is written to:

```
<constraintLabel>Report.txt
```

This file lists, for each numerical parameter, the convergence measure and its error achieved by the ideal model. Additionally a normalized measure (the measure divided by its error) is listed. This normalized measure can be approximately interpretted as the number of σ deviation from convergence.

9.3. Model Discrepancy

Model discrepancy scripts process the model described by a standard Galacticus constraints configuration file to produce an output HDF5 file which describes a particular contribution to the model discrepancy. The format of these files is

```
HDF5 "discrepancy.hdf5" {
GROUP "/" {
   DATASET "additive" {
   }
   DATASET "multiplicative" {
   }
   DATASET "covariance" {
   }
}
```

[1] "Significant distance" here requires some judgement. Typically we would like for the model results to not change significantly as the value of a numerical parameter is adjusted by at least a factor of 2 away from the ideal value.

Each of the three datasets is optional (i.e. not all need be provided for each discrepancy). The `additive` dataset gives an additive offset which will be applied to the relevant model results. The `multiplicative` dataset similarly gives a multiplicative offset which will be applied to the relevant model results. Finally, the `covariance` dataset gives the contribution from this discrepancy to the covariance matrix used in evaluating the model likelihood.

Discrepancy files are written to

```
<workDirectory>/modelDiscrepancy/<discrepancyLabel>/discrepancy<constraintLabel>.hdf5
```

Constraint scripts (see §9.5) accept a command line option `-modelDiscrepancies` which specifies the path to the `modelDiscrepancy` directory (i.e. `<workDirectory>/modelDiscrepancy`) and will search for any relevant model discrepancy files and apply them in their calculations.

9.3.1. Monte Carlo Merger Trees

Galacticus typically uses Monte Carlo-generated merger trees when being constrained to fit data. These have the advantage that they can be generated for any cosmological parameters (necessary if the cosmological parameters are to be varied as part of the constraining process) and they can be generated uniquely for each model evaluation which avoids any bias introduced by using a fixed set of halos.

However, these Monte Carlo-generated trees may not precisely capture the properties of merger trees derived from a fully non-linear calculation of gravitational collapse (e.g. as performed by an N-body simulation). Therefore it is important to assess the model discrepancy arising from this limitation.

Model discrepancy files can be generated using:

```
constraints/modelDiscrepancy/monteCarloTrees.pl config.xml
```

where `config.xml` is a standard Galacticus constraint configuration file. The script will run two sets of models, one using N-body merger trees derived from the Millennium Simulation, and a second using Monte Carlo-generated merger trees. The number of subvolumes of the Millennium Simulation to use is specified by the `subVolumeCount` option to this script (a default of 32 subvolumes is used if no number is specified). The subvolume data will be downloaded from the Millennium Simulation database if necessary.

To make a fair comparison, Millennium Simulation merger trees have their branches pruned below a mass corresponding to 20 particles, and the Monte Carlo merger trees are built with the equivalent mass resolution. Additionally, the Monte Carlo merger trees are regridded onto a set of timesteps matched to the Millennium Simulation.

A multiplicative model discrepancy is computed for each constraint included in the compilation (as specified in the configuration file) equal to the ratio of the N-body result to the Monte Carlo result. Additionally, the subvolumes of the Millennium Simulation are used to estimate the covariance in the N-body result due to the finite volume of the simulation. The result is computed for each subvolume separately and the covariance of the result between subvolumes computed. This is repeated using pairs of subvolumes, quads of subvolumes, etc. If 2^n subvolumes were used, then the covariance measured from the result combining 2^{n-3} subvolumes is used to extrapolate the covariance for all 512 subvolumes assuming that the covariance scales in inverse proportion to the number of subvolume used. Finally, the contribution of the Monte Carlo trees model to the covariance is assumed to be a diagonal matrix with elements equal to the square of the reported errors on the result of the model.

9.3.2. Fixed Virial Orbits

The orbital parameters of subhalos at the point of virial orbit crossing are usually drawn from an appropriate cosmological distribution. If instead fixed virial orbital parameters are used instead then term should be included in the model discrepancy accounting for this approximation.

Model discrepancy files can be generated using:

```
constraints/modelDiscrepancy/fixedVirialOrbits.pl config.xml
```

where `config.xml` is a standard Galacticus constraint configuration file. The script will run two models, one using fixed virial orbital parameters, and a second using variable orbital parameters using the `Benson2005` method (see §12.51.2). A multiplicative model discrepancy is computed for each constraint included in the compilation (as specified in the configuration file) equal to the ratio of the variable orbits result to the fixed orbits result. Additionally, a model discrepancy covariance is computed. This is assumed to be a diagonal matrix with elements equal to the square of the reported errors on the results of the fixed and variable orbital parameters models.

9.3.3. Jiang et al. (2008) Merger Time Scatter

The Jiang et al. [2008] algorithm for the merging times of dark matter subhalos includes drawing times from a log-normal distribution of width $\sigma = 0.4$ with median equal to their fitting function (see §12.51.1). If instead zero scatter is used then a term should be included in the model discrepancy accounting for this approximation.

Model discrepancy files can be generated using:

```
constraints/modelDiscrepancy/jiang2008MergingTimeScatter.pl config.xml
```

where `config.xml` is a standard Galacticus constraint configuration file. The script will run two models, one using the default scatter specified by the configuration file, and a second using $\sigma = 0.4$. A multiplicative model discrepancy is computed for each constraint included in the compilation (as specified in the configuration file) equal to the ratio of the $\sigma = 0.4$ and default scatter results. Additionally, a model discrepancy covariance is computed. This is assumed to be a diagonal matrix with elements equal to the sum of the square of the reported errors on the result of the default scatter and $\sigma = 0.4$ models.

9.4. Optimal Halo Mass Function Sampling

Suppose we want to fit parameters of the Galacticus model to some dataset. The basic approach is to generate large numbers of model realizations for different parameter values and see which ones best match the data. Galacticus models involve simulating individual merger trees and then adding together their galaxies to produce some overall function. The question we want to answer is, given some finite amount of computing time, what is the optimal distribution of halo masses to run when comparing to a given dataset. For example, is it better to run a volume limited sample (as one would get from an N-body simulation) or is it better to use, say, equal numbers of halos per logarithmic interval of halo mass? The following section describes how to solve this optimization problem in the specific case of fitting to the stellar mass function.

9.4.1. Li & White (2009) Stellar Mass Function

First, some definitions:

$n(M)\mathrm{d}\ln M$ is the dark matter halo mass function, i.e. the number of halos in the range M to $M + M\mathrm{d}\ln M$ per unit volume;

$\gamma(M)\mathrm{d}\ln M$ is the number of trees that we will simulate in the range M to $M + M\mathrm{d}\ln M$;

$\alpha(M_\star)$ is the error on the observed stellar mass function at mass $M_\star$;

$P(N|M_\star, M; \delta\ln M_\star)$ is the conditional stellar mass distribution function of galaxies of stellar mass $M_\star$ in a bin of width $\delta\ln M_\star$ per halo of mass M;

$t(M)$ is the CPU time it takes to simulate a tree of mass M.

To clarify, $P(N|M_\star, M; \delta \ln M_\star; \delta \ln M_\star)$ is the probability[2] to find N galaxies of mass between $M_\star$ in a bin of width $\delta \ln M_\star$ in a halo of mass M. The usual conditional stellar mass function is simply the first moment of this distribution:

$$\phi(M_\star; M)\delta \ln M_\star = \sum_{N=0}^{\infty} N P(N|M_\star, M; \delta \ln M_\star) \tag{9.2}$$

The model estimate of the stellar mass function $\Phi(M_\star)$ (defined per unit $\ln M_\star$) is

$$\Phi(M_\star) = \int_0^\infty \phi(M_\star; M) \frac{n(M)}{\gamma(M)} \gamma(M) \mathrm{d} \ln M, \tag{9.3}$$

where the $n(M)/\gamma(M)$ term is the weight assigned to each tree realization—and therefore the weight assigned to each model galaxy when summing over a model realization to construct the stellar mass function.

When computing a model likelihood, we must employ some statistic which defines how likely the model is given the data. Typically, for stellar mass functions we have an estimate of the variance in the data, $\alpha^2(M_\star)$, as a function of stellar mass (full covariance matrices are typically not provided but, ideally would be, and can be easily incorporated into this method). In that case, we can define a likelihood

$$\ln \mathcal{L} = -\frac{1}{2} \sum_i \frac{[\phi_{\mathrm{obs},i} - \phi_i]^2}{\alpha_i^2 + \sigma_i^2} \tag{9.4}$$

where the sum is taken over all data points, i, and σ_i^2 is the variance in the model estimate and is given by

$$\sigma^2(M_\star) = \langle [\phi(M_\star) - \bar{\phi}(M_\star)]^2 \rangle, \tag{9.5}$$

where $\phi(M_\star)$ is the realization from a single model and $\bar{\phi}(M_\star)$ is the model expectation from an infinite number of merger tree realizations and the average is taken over all possible model realizations. Since the contributions from each merger tree are independent,

$$\sigma^2(M_\star) = \sum_i \zeta_i^2(M_\star; M) \tag{9.6}$$

where $\zeta_i^2(M_\star; M)$ is the variance in the contribution to the stellar mass function from tree i. This in turn is given by

$$\zeta^2(M_\star; M) = \psi^2(M_\star; M) \left[\frac{n(M)}{\gamma(M)}\right]^2, \tag{9.7}$$

where $\psi^2(M_\star; M)$ is the variance in the conditional stellar mass function. In the continuum limit this becomes

$$\sigma^2(M_\star) = \int_0^\infty \psi^2(M_\star; M) \left[\frac{n(M)}{\gamma(M)}\right]^2 \gamma(M) \mathrm{d} \ln M. \tag{9.8}$$

Model variance artificially increases the likelihood of a given model. We would therefore like to minimize the increase in the likelihood due to the model variance:

$$\Delta 2 \ln \mathcal{L} = \sum_i \frac{[\phi_{\mathrm{obs},i} - \phi_i]^2}{\alpha_i^2} - \frac{[\phi_{\mathrm{obs},i} - \phi_i]^2}{\alpha_i^2 + \sigma_i^2} \tag{9.9}$$

[2]To put it another way, $P(N|M_\star, M; \delta \ln M_\star)$ is closely related to the commonly used Halo Occupation Distribution.

Of course, we don't know the model prediction, ϕ_i, in advance[3]. However, if we assume that a model exists which is a good fit to the data then we would expect that $[\phi_{\mathrm{obs},i} - \phi_i]^2 \approx \alpha_i^2$ on average. In that case, the increase in likelihood due to the model is minimized by minimizing the function[4]

$$F[\gamma(M)] = \sum_i \frac{\alpha_i^2}{\alpha_i^2 + \sigma_i^2}. \tag{9.10}$$

If the bins all have the same $\delta \ln M_\star$ we can turn the sum into an integral

$$F[\gamma(M)] = \int_0^\infty \frac{\alpha(M_\star)^2}{\alpha(M_\star)^2 + \sigma(M_\star)^2} \mathrm{d} \ln M_\star. \tag{9.11}$$

Obviously, the answer is to make $\gamma(M) = \infty$, in which case $F[\gamma(M)] = 0$. However, we have finite computing resources. The total time to run our calculation is

$$\tau = \int_0^\infty t(M)\gamma(M) \mathrm{d} \ln M. \tag{9.12}$$

We therefore want to minimize $F[\gamma(M)]$ while keeping τ equal to some finite value. We can do this using a Lagrange multiplier and minimizing the function

$$F[\gamma(M)] = \int_0^\infty \frac{\alpha(M_\star)^2}{\alpha(M_\star)^2 + \sigma(M_\star)^2} \mathrm{d} \ln M_\star + \int_0^\infty \lambda\gamma(M)t(M) \mathrm{d} \ln M. \tag{9.13}$$

Finding the functional derivative and setting it equal to zero gives:

$$\gamma(M) = \sqrt{\frac{\xi(M)}{\lambda t(M)}}, \tag{9.14}$$

in the limit where[5] $\sigma(M_\star) \ll \alpha(M_\star)$, and where

$$\xi(M) = n^2(M) \int_{-\infty}^\infty \frac{\psi^2(M_\star; M)}{\alpha^2(M_\star)} \mathrm{d} \ln M_\star. \tag{9.15}$$

The values of λ and $\delta \ln M_\star$, and the normalization of $t(M)$ are unimportant here since we merely want to find the optimal shape of the $\gamma(M)$ function—we can then scale it up or down to use the available time.

Figure 9.2 shows the function $\gamma(M)$ obtained by adopting a model conditional stellar mass function which is a sum of central and satellite terms. Specifically, we use the model of Leauthaud et al. [2011] which is constrained to match observations from the COSMOS survey. In their model[6]:

$$\langle N_\mathrm{c}(M_\star|M) \rangle \equiv \int_{M_\star}^\infty \phi_\mathrm{c}(M'_\star) \mathrm{d} \ln M'_\star = \frac{1}{2} \left[1 - \mathrm{erf} \left(\frac{\log_{10} M_\star - \log_{10} f_\mathrm{SHMR}(M)}{\sqrt{2} \sigma_{\log M_\star}} \right) \right]. \tag{9.16}$$

Here, the function $f_\mathrm{SHMR}(M)$ is the solution of

$$\log_{10} M = \log_{10} M_1 + \beta \log_{10} \left(\frac{M_\star}{M_{\star,0}} \right) + \frac{(M_\star/M_{\star,0})^\delta}{1 + (M_\star/M_{\star,0})^{-\gamma}} - 1/2. \tag{9.17}$$

[3] Below, we will adopt a simple empirical model for $\phi(M_\star)$. However, it should not be used here since we will in actuality be computing the likelihood from the model itself.

[4] This can be seen intuitively: we are simply requring that the variance in the model prediction is small compared the the variance in the data.

[5] This is the limit in which we would like our results to be.

[6] This integral form of the conditional stellar mass function is convenient here since it allows for easy calcualtion of the number of galaxies expected in the finite-width bins of the observed stellar mass function.

Table 9.1.: Parameters of the conditional stellar mass function fit.

Parameter	Value
$\alpha_{\rm sat}$	1.0
$\log_{10} M_1$	12.120
$\log_{10} M_{\star,0}$	10.516
β	0.430
δ	0.5666
γ	1.53
$\sigma_{\log M_\star}$	0.206
$B_{\rm cut}$	0.744
$B_{\rm sat}$	8.00
$\beta_{\rm cut}$	−0.13
$\beta_{\rm sat}$	0.859

For satellites,

$$\langle N_{\rm s}(M_\star|M)\rangle \equiv \int_{M_\star}^{\infty} \phi_{\rm s}(M'_\star){\rm d}\ln M'_\star = \langle N_{\rm c}(M_\star|M)\rangle \left(\frac{f^{-1}_{\rm SHMR}(M_\star)}{M_{\rm sat}}\right)^{\alpha_{\rm sat}} \exp\left(-\frac{M_{\rm cut}}{f^{-1}_{\rm SHMR}(M_\star)}\right), \quad (9.18)$$

where

$$\frac{M_{\rm sat}}{10^{12}M_\odot} = B_{\rm sat}\left(\frac{f^{-1}_{\rm SHMR}(M_\star)}{10^{12}M_\odot}\right)^{\beta_{\rm sat}}, \quad (9.19)$$

and

$$\frac{M_{\rm cut}}{10^{12}M_\odot} = B_{\rm cut}\left(\frac{f^{-1}_{\rm SHMR}(M_\star)}{10^{12}M_\odot}\right)^{\beta_{\rm cut}}. \quad (9.20)$$

We use the best fit parameters from the `SIG_MOD1` method of Leauthaud et al. [2011] for their z_1 sample, but apply a shift of -0.2 dex in masses to bring the fit into line with the $z = 0.07$ mass function of Li and White [2009]. The resulting parameter values are shown in Table 9.1.

We assume that $P_{\rm s}(N|M_\star, M; \delta\ln M_\star)$ is a Poisson distribution while $P_{\rm c}(N|M_\star, M; \delta\ln M_\star)$ has a Bernoulli distribution, with each distribution's free parameter fixed by the constraint of eqn. (9.2), and the assumed forms for $\phi_{\rm c}$ and $\phi_{\rm s}$.

The errors in the Li and White [2009] observed stellar mass function are well fit by (see Fig. 9.1):

$$\alpha(M_\star) = 10^{-3}\left(\frac{M_\star}{4.5\times10^{10}M_\odot}\right)^{-0.3}\exp\left(-\frac{M_\star}{4.5\times10^{10}M_\odot}\right) + 10^{-7}, \quad (9.21)$$

and the tree processing time in Galacticus can be described by:

$$\log_{10} t(M) = \sum_{i=0}^{2} C_i[\log_{10} M]^i \quad (9.22)$$

with $C_0 = -0.73$, $C_1 = -0.20$ and $C_2 = 0.035$.

The resulting optimal sampling density curve is shown in Fig. 9.2 and is compared to weighting by the halo mass function (i.e. the result of sampling halos at random from a representative volume). Optimal sampling gives less weight to low mass halos (since a sufficient accuracy can be obtained without the need to run many tens of thousands of such halos) and to high mass halos which are computationally expensive.

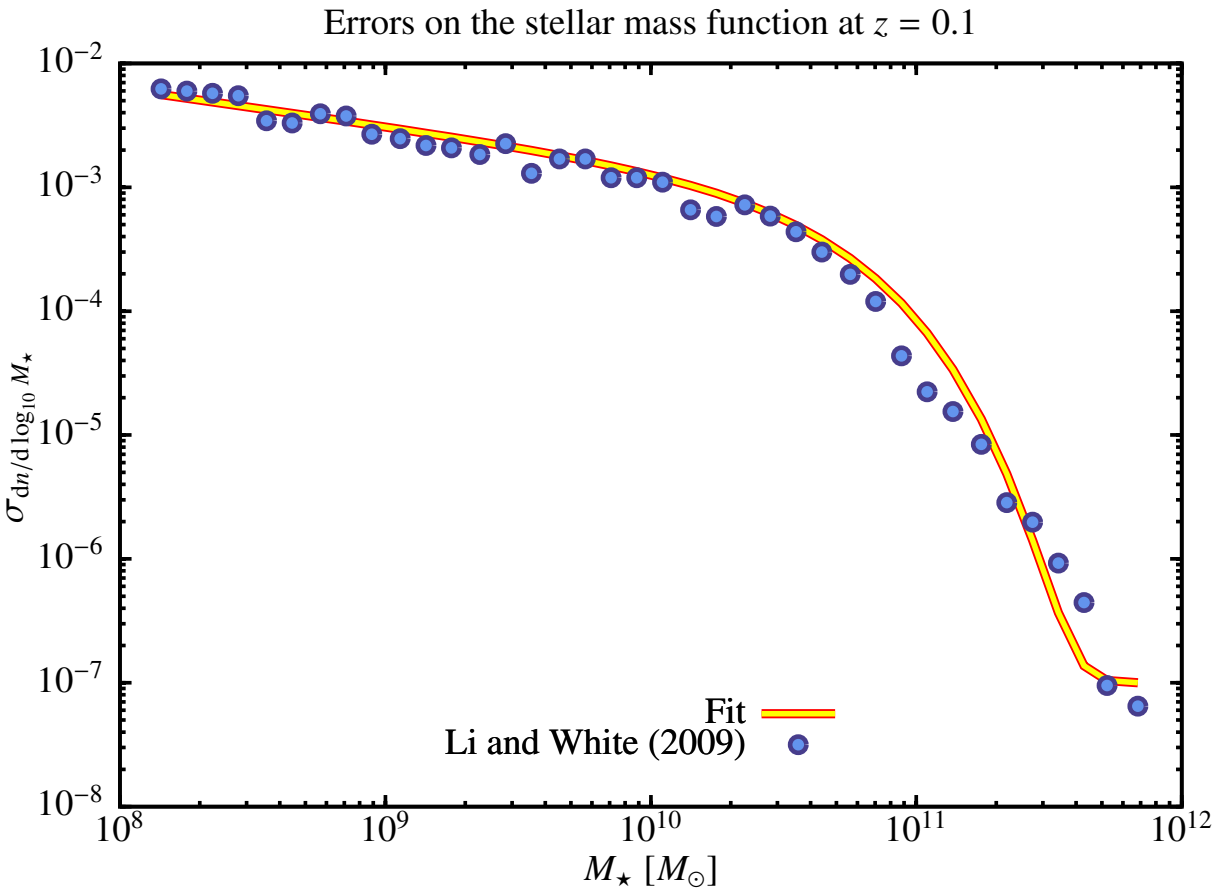

Figure 9.1.: Errors on the Li and White [2009] stellar mass funtion (points) and the fitting function (line) given by eqn. (9.21).

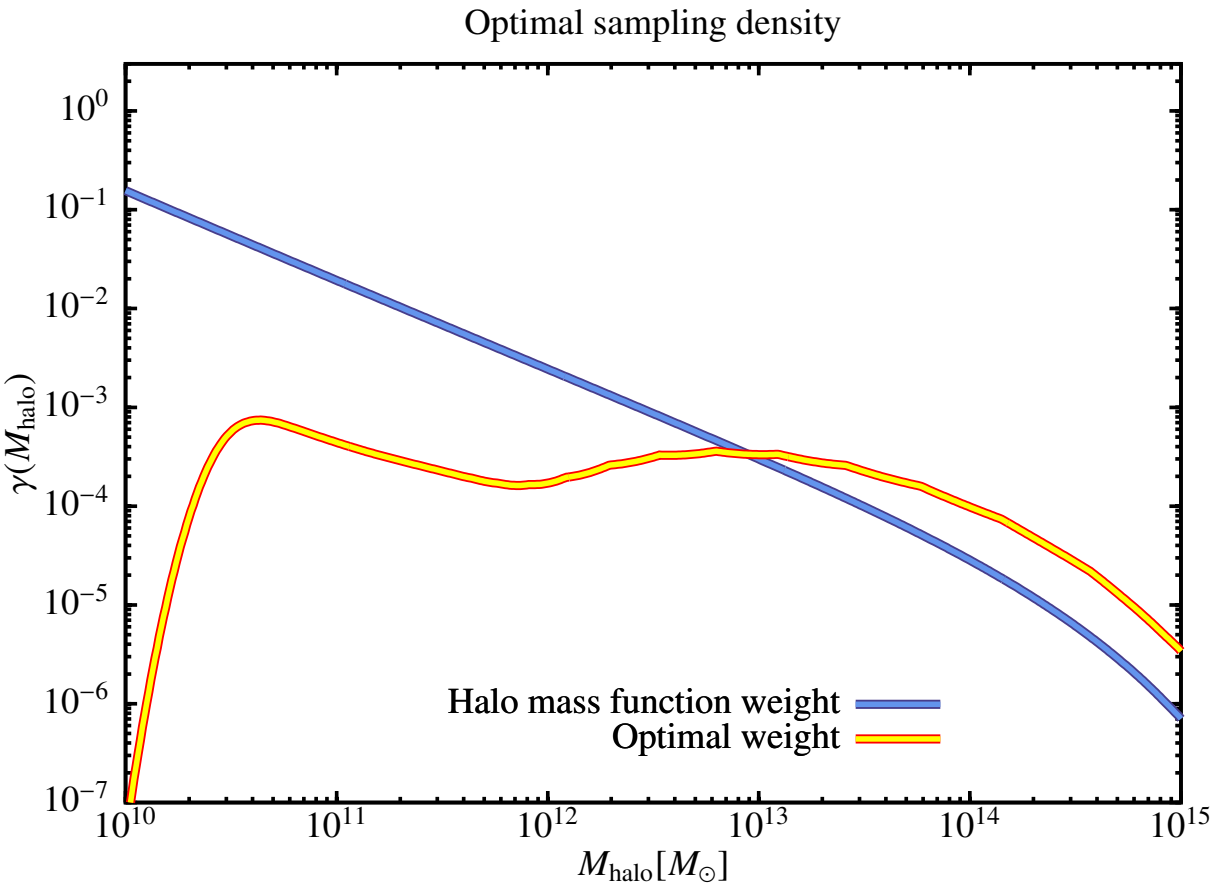

Figure 9.2.: Optimal weighting (yellow line) compared with weighting by the dark matter halo mass function (i.e. sampling halos at random from a representative volume; blue line). Sampling densities have been normalized to unit compute time.

9.4.2. Refining by Other Merger Tree Statistics

Since building merger trees is relatively fast, while solving the baryonic physics is slow it may be advantageous to non-uniformly sample the distribution of merger trees at fixed merger tree mass, M. For example, we could assign some measure of formation history to each merger tree, such as the time since the last major merger, τ. The halo mass function then becomes $n(M,\tau)$ (which can be computed by simulating large numbers of trees), and the tree sampling function becomes $\gamma(M,\tau)$. We'd then need to know the stellar mass function conditioned on both M and τ, $\phi_\star(M_\star|M,\tau)$. Given these, the above approach could be easily generalized to determine an optimal $\gamma(M,\tau)$. Then, after generating a merger tree, we'd first compute τ. If a sufficient number of trees in that τ interval had already been computed, then we'd simply drop that tree and compute another one. The speed up here would depend on how fast building trees is relative to solving baryonic physics and what fraction of trees you discard. In principle, the trees could be generated, sampled and stored in advance so that we'd already have an optimally distributed set of trees in M and τ that could be used for each model run.

9.5. Constraints

Any constraint which can be applied to Galacticus is defined by two files, a configuration file and a likelihood script, which must be placed in `constraints/constraints` and `constraints/scripts` respectively.

9.5.1. Configuration File

The configuration file should have the form:

```
<!-- Defines a constraint to match some data. -->
<constraint>
  <name>Long-form name of this constraint</name>
  <label>shortLabelForThisConstraint</label>
  <outputRedshift>0.07</outputRedshift>
  <outputRedshift>1.00</outputRedshift>
  <haloMassResolution>5.0e9</haloMassResolution>
  <haloMassMinimum>2.0e10</haloMassMinimum>
  <haloMassMaximum>2.0e14</haloMassMaximum>
  <analysis>constraints/scripts/myAnalysisScript.pl</analysis>
  <luminosity>
    <filter>UKIRT_K</filter>
    <redshift>0.0</redshift>
    <frame>rest</frame>
  </luminosity>
  <luminosity>
    <filter>UKIRT_K</filter>
    <redshift>1.0</redshift>
    <frame>observed</frame>
  </luminosity>
  <optionOn>outputMainBranchStatus</optionOn>
  <optionOn>outputDensityContrastData</optionOn>
  <parameter>
   <name>outputDensityContrastValues</name>
   <value>200.0</value>
```

```
   <accumulation>unique</accumulation>
  </parameter>
</constraint>
```

The `name` and `label` are used to describe the constraint (`label` is used as a suffix in file names so should not contain spaces or other characters which might cause problems in file names).

The remaining elements describe the requirements for this constraint. `haloMassResolution` specifies the maximum resolution in mergers trees that still allows this constraint to be computed accurately. Similarly, `haloMassMinimum` and `haloMassMaximum` specify the required range of halo masses to simulate to allow this constraint to be computed accurately.

One or more `outputRedshift` elements may be present, each specifying a redshift at which output is required for this constraint. Similarly, one or more `luminosity` elements may be present, each of which specifies a luminosity which must be computed for this constraint. Each `luminosity` must contain a specification of `filter`, `redshift`, and `frame` to define which luminosity is to be computed.

One or more `optionOn` elements may be present. Each element must specify the name of a Galacticus input parameter. That parameter will be set to `true` in the Galacticus input parameter file.

Finally, arbitrary other parameter may be set using the standard `parameter` element which should give the `name` and `value` for the parameter. Optionally, an `accumulation` element may also be specified for each `parameter`. This controls how values of the parameter are to be accumulated if set by more than one constraint. An accumulation of `overwrite` will simply overwrite any previously set values. An accumulation of `combine` will concatenate all values set by different constraints. Finally, an accumulation of `unique` will concatenate all values set by different constraints and then filter out any duplicates.

When multiple constraints are used, their requirements are automatically combined.

9.5.2. Likelihood Script

The likelihood script for a constraint is required to perform several tasks, controlled by command line options. The script should accept the following command line syntax:

```
myScript.pl <galacticusFile> [options...]
```

where `galacticusFile` is the file name of the Galacticus model for which the likelihood calculation should be performed. The following options must be supported by the script:

`-plotFile <fileName>` If this option is present, the script should generate a plot showing the constraint and the model result and write it to `fileName`.

`-outputFile <fileName>` If this option is present, the script should compute the log-likelihood of the model given the constraint and write it to `fileName` using the format

```
<constraint>
 <logLikelihood>-123</logLikelihood>
</constraint>
```

`-accuracyFile <fileName>` If this option is present, the script should write an XML file giving details of the accuracy of the model results relative to the observational errors using the format

```
<accuracy>
 <x>...</x>
 .
 .
 .
```

```
 <x>...</x>
 <yModel>...</yModel>
 .
 .
 .
 <yModel>...</yModel>
 <yData>...</yData>
 .
 .
 .
 <yData>...</yData>
 <errorModel>...</errorModel>
 .
 .
 .
 <errorModel>...</errorModel>
 <errorData>...</errorData>
 .
 .
 .
 <errorData>...</errorData>
</accuracy>
```

In this file the `yModel` and `yData` elements should give the values of the model result and the comparable data respectively, while `errorModel` and `errorData` should give an estimate of the errors on these quantities. In the case of the model error this should include only the contribution arising from the finite number of merger trees simulated. This file will be used to judge whether the model is running sufficient merger trees such that the likelihood is not dominated by these errors. The `x` elements are optional but can be used to give the parameter values associated with each model result.

`-resultFile <fileName>` If this option is present, the script should write an XML file giving details of the result of the model using the format

```
<accuracy>
 <x>...</x>
 .
 .
 .
 <x>...</x>
 <y>...</y>
 .
 .
 .
 <y>...</y>
 <error>...</error>
 .
 .
 .
 <error>...</error>
</accuracy>
```

In this file the `y` elements should give the values of the model result, while the `error` elements should give an estimate of the errors on these results. The error should include only the contribution arising from the finite number of merger trees simulated. This file will be used to judge whether the model result is converged with respect to various numerical parameters in Galacticus. The `x` elements are optional but can be used to give the parameter values associated with each model result.

`-modelDiscrepancies <path>` If this option is present, the script should scan `path`. For each directory found in `path` the script should check for the existance of a file named `discrepancy<label>.hdf5` where `label` is the label given for this constraint in its configuration file (see §9.5.1). If present, the model discrepancy given in that file should be applied to the likelihood calculation. See §9.3 for a description of the structure of the discrepancy files.

9.5.3. Available Constraints

Methodology for Mass Functions

In general, for constraints corresponding to mass functions (whether stellar mass or HI mass), the covariance matrix of the observational data is determined using the analytic model of Smith [2012]. This requires knowledge of both the survey geometry (angular mask and radial extent as a function of mass) and of the halo occupation distribution (HOD) of the observed galaxies.

Details of the survey geometry and depth are given for each individual constraints. Computing the large-scale structure contribution to the covariance function requires integration of the non-linear matter power spectrum over the Fourier transform of the survey window function. We use the method of Peacock and Dodds [1996] to determine the non-linear matter power spectrum, because of its simplicity and speed. We have checked that using a more accurate non-linear matter power spectrum (e.g. Lawrence et al. 2010) makes negligible difference to our results. If the angular power spectrum of the survey mask is available[7], this is used to compute the relation

$$\sigma^2(M_\mu, M_\nu) = \frac{2}{\pi V_\mu V_\nu} \int_0^\infty \mathrm{d}k\, k^{-4} P(k) \sum_i \sum_j \sum_{\ell=0}^\infty (2\ell+1) C_\ell^{ij} R_\ell^i(kr_{\mu 0}, kr_{\mu 1}) R_\ell^j(kr_{\nu 0}, kr_{\nu 1}), \tag{9.23}$$

where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, $\Psi_{\ell m}^i$ are the spherical harmonic coefficients of the i^{th} field of the survey, V is the maximum distance to which a galaxy of mass M can be seen, $P(k)$ is the nonlinear power spectrum and

$$R_\ell(x_0, x_1) \equiv \int_{x_0}^{x_1} x^2 j_\ell(x) \mathrm{d}x = \sqrt{\pi} 2^{-2-\ell} \Gamma\left(\frac{1}{2}[3+\ell]\right) \left[x^{3+\ell}\, {}_1\widetilde{F}_2\left(\frac{1}{2}[3+\ell]; \ell+\frac{3}{2}, \frac{1}{2}(5+\ell); -\frac{x^2}{4}\right)\right]_{x_0}^{x_1}, \tag{9.24}$$

where ${}_1\widetilde{F}_2$ is the regularized generalized hypergeometric function. In other cases, where the angular power spectrum is not available, the survey geometry is realized on a grid which is when Fourier transformed to obtain the appropriate window function.

To find a suitable HOD to describe the observed galaxies we adopt the model of Behroozi et al. [2010]. This is an 11 parameter model which describes separately the numbers of satellite and central galaxies occupying a halo of given mass—the reader is referred to Behroozi et al. [2010] for a complete description of the functional form of this parametric HOD. An Markov Chain Monte Carlo (MCMC) approach is used to to constrain the HOD parameters to fit the observational data. We use a likelihood

$$\ln \mathcal{L} = -\frac{1}{2} \Delta \cdot \mathcal{C}^{-1} \cdot \Delta^{\mathrm{T}} - \frac{N}{2} \ln(2\pi) - \frac{\ln |\mathcal{C}|}{2}, \tag{9.25}$$

[7] Typically if the survey geometry is defined by mangle polygons, allowing the angular power spectrum to be found using the mangle `harmonize` utility.

where N is the number of bins in the mass function, $\mathcal{C}$ is the covariance matrix of the observed mass function, and $\Delta_i = \phi_i^{(\mathrm{HOD})} - \phi_i^{(\mathrm{observed})}$. Of course, it is precisely this covariance matrix, $\mathcal{C}$, that we are trying to compute. We therefore adopt an iterative approach as follows:

1. make an initial estimate of the covariance matrix, assuming that only Poisson errors contribute (the covariance matrix is therefore diagonal, and the terms are easily computed from the measured mass function and the survey volume as a function of stellar mass);
2. find the maximum likelihood parameters of the HOD given the observed mass function and the current estimate of the covariance matrix;
3. using this HOD and the framework of Smith [2012], compute a new estimate of the covariance matrix, including all three contributions;
4. repeat steps 2 and 3 until convergence in the covariance matrix is achieved.

In practice we find that this procedure often leads to an HOD and covariance matrix which oscillate between two states in successive iterations. The differences in the covariance matrix are relatively small however, so we choose to conservatively adopt the covariance matrix with the larger values.

Methodology for Correlation Functions

For constraints corresponding to (possibly, projected) correlation functions, the model expectation is computed using the halo model Cooray and Sheth [2002]. For each model halo, each galaxy (satellite and central) is assessed to see if it meets the criteria for inclusion in the sample. Where the sample includes mass limits (either just a lower limit, or lower and upper limits) each galaxy is assigned a probability of inclusion in the sample based on its mass and the random error in mass. Thus, each halo is characterized by the probability of having a central galaxy in the sample, $p^{(\mathrm{c})}$, and N probabilities, $p_i^{(\mathrm{s})}$, of each satellite galaxy being in the sample. We assume binomial statistics for each galaxy's probability of inclusion, and further assume that these probabilities are uncorrelated. Therefore, the contribution of the halo to the one- and two-halo terms of the power spectrum in the halo model are:

$$\Delta P^{1\mathrm{h}}(k) = \frac{w}{n_{\mathrm{gal}}^2}\left[p^{(\mathrm{c})}\sum_{i=1}^{N} p^{(\mathrm{s})} u(k|M) + \sum_{k=0}^{N} k(k-1) P\left(p_i^{(\mathrm{s})},\ldots,p_N^{(\mathrm{s})}\right) u(k|M)^2\right] \tag{9.26}$$

and

$$\Delta\sqrt{P^{2\mathrm{h}}}(k) = \frac{w}{n_{\mathrm{gal}}}\sqrt{P^{\mathrm{lin}}}(k) b(M) u(k|M)\left[p^{(\mathrm{c})} + \sum_{i=1}^{N} p_i^{(\mathrm{s})}\right], \tag{9.27}$$

respectively, where w is the weight of the halo (i.e. the number of such model halos expected per unit volume), $b(M)$ is the bias of halos of mass M, $u(k|M)$ is the Fourier-transform of the halo density profile, and $P_{\mathrm{lin}}(k)$ is the linear theory power spectrum, and $P(p_1,\ldots,p_N)$ is the Poisson binomial distribution for N events with probabilities $p_1,\ldots,p_N$. The contribution of the halo to the galaxy density, n_{gal}, is simply $\Delta n_{\mathrm{gal}} = w\left[p^{(\mathrm{c})} + \sum_{i=1}^{N} p_i^{(\mathrm{s})}\right]$.

Li & White (2009) SDSS Stellar Mass Function

This constraint utilizes the stellar mass function for $z \approx 0.07$ galaxies measured by Li and White [2009] from the Sloan Digitial Sky Survey (SDSS). The mass function reported by Li and White [2009] is converted to the appropriate Hubble constant for the given Galacticus model (assuming that masses scale as H_0^{-2} and volumes as H_0^3)—no adjustment is made for cosmological parameters given the low redshift of the sample.

Given a Galacticus model, total stellar masses of model galaxies are adjusted using:

$$M_\star \rightarrow \mathbf{GS} M_\star \tag{9.28}$$

where the $\mathbf{S}$ operator is a multiplicative factor accounting for systematic errors in stellar mass determination and is equal to [Behroozi et al., 2010]

$$\log_{10} S = \mu + \kappa \log_{10} \left(\frac{M_\star}{10^{11.3} M_\odot} \right) \tag{9.29}$$

where $\mu =$ `[sdssStellarMassFunctionZ0.07StellarMassSystematicMu]`, $\kappa =$ `[sdssStellarMassFunctionZ0.07StellarMa` and the $\mathbf{G}$ operator is a multiplicative factor drawn from a log-normal distribution of width 0.07 dex for each galaxy to mimic the effects of random errors on stellar masses (motivated by the discussion of Behroozi et al. [2010]).

The model masses are then used to construct a mass function by binning into a histogram using the masses reported by Li and White [2009] (modified as described above) as the centers of the bins (with bin boundaries placed at the geometric means of consecutive bin centers).

If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_\mathrm{obs} + \mathbf{C}_\mathrm{model,random} + \sum_i \mathbf{C}_\mathrm{discrepancy},_i, \tag{9.30}$$

where $\mathbf{C}_\mathrm{obs}$ is the covariance matrix of the observational data, $\mathbf{C}_\mathrm{model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated—see §9.5.3 for a description of how this covariance matrix is estimated), and $\mathbf{C}_\mathrm{discrepancy},_i$ is the covariance due to the i^th model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp \left[-\frac{1}{2} \Delta \mathbf{C}^{-1} \Delta \right], \tag{9.31}$$

where $\Delta_i = \Phi_\mathrm{model},_i - \Phi_\mathrm{observed},_i$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

Caputi et al. (2011) UKIDSS UDS Stellar Mass Function

This constraint utilizes the stellar mass functions for $z = 3$ to 5 galaxies measured by Caputi et al. [2011] from the UKISS UDS survey. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

Given a Galacticus model, total stellar masses of model galaxies are adjusted using:

$$M_\star \rightarrow \mathbf{GS} M_\star \tag{9.32}$$

where the $\mathbf{S}$ operator is a multiplicative factor accounting for systematic errors in stellar mass determination and is equal to [Behroozi et al., 2010]

$$\log_{10} S = \mu + \kappa \log_{10} \left(\frac{M_\star}{10^{11.3} M_\odot} \right) \tag{9.33}$$

where $\mu =$ `[ukidssUdsStellarMassFunctionZX.XXXStellarMassSystematicMu]`, $\kappa =$ `[ukidssUdsStellarMassFunctionZX.` and the $\mathbf{G}$ operator is a multiplicative factor drawn from a log-normal distribution of width 0.173 dex

for each galaxy to mimic the effects of random errors on stellar masses (which accounts for errors in photometric redshifts, $\delta z/(1+z)$ of $\sigma = 0.05$ as reported by Caputi et al. [2011] along with an additional 0.087 dex added in quadrature to account for SED fitting errors, judged from Figure 8 of Caputi et al. [2011]).

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.34}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta \mathbf{C}^{-1} \Delta\right], \tag{9.35}$$

where $\Delta_i = \Phi_{{\rm model},i} - \Phi_{{\rm observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

The survey window function is determined from the set of galaxy positions provided by Caputi (private communication), by finding a suitable bounding box and then cutting out empty regions (corresponding to regions that were removed around bright stars). A set of random points are then found within this mask and are used to find the Fourier transform of the survey volume.

To estimate the depth of the Caputi et al. [2011] sample as a function of galaxy stellar mass we make use of semi-analytic models in the Millennium Database. Specifically, we use the semi-analytic models (SAMs) of Guo et al. [2011] and Henriques et al. [2012] specifically the `Guo2010a..MR` and `Henriques2012a.wmap1.BC03_001` tables in the Millennium Database. For each snapshot in the database, we extract the stellar masses and observed-frame IRAC 4.5μm apparent magnitudes (including dust extinction), and determine the median apparent magnitude as a function of stellar mass. Using the limiting apparent magnitude of the Caputi et al. [2011] sample, $i_{4.5} = 24$, we infer the corresponding absolute magnitude at each redshift and, using our derived apparent magnitude–stellar mass relation, infer the corresponding stellar mass.

The end result of this procedure is the limiting stellar mass as a function of redshift, accounting for k-corrections, evolution, and the effects of dust. Figure 9.5.3 shows the resulting relation between stellar mass and the maximum redshift at which such a galaxy would be included in the sample. Points indicate measurements from the SAM, while the line shows a polynomial fit:

$$z(M_\star) = -56.247 + 5.881 m, \tag{9.36}$$

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

Finally, the incompleteness of the observational sample (which is required when estimating the Poisson contribution to the covariance matrix) is found from the 50% and 80% completeness masses, M_{50} and M_{80} respectively, given in Fig. 4 of Caputi et al. [2011]. Specifically, we assume that, at a given mass M, the number of photons being received from a galaxy can be modeled as a Gaussian distribution with mean fM and variance $fM + \mu$, where μ is the number of photons ariving from the sky. The fraction of sources of mass M that will be detected at more than $n\sigma$ above the background is then

$$\begin{aligned} f(M) &= \int_{n\sqrt{mu}}^{\infty} \frac{1}{\sqrt{2\pi}\sqrt{fM+\mu}} \exp\left(-\frac{[S-fM]^2}{2[fM+\mu]}\right) {\rm d}S \\ &= \frac{1}{2}\left[1 - {\rm erf}\left(\frac{x(M)}{\sqrt{2}}\right)\right], \end{aligned} \tag{9.37}$$

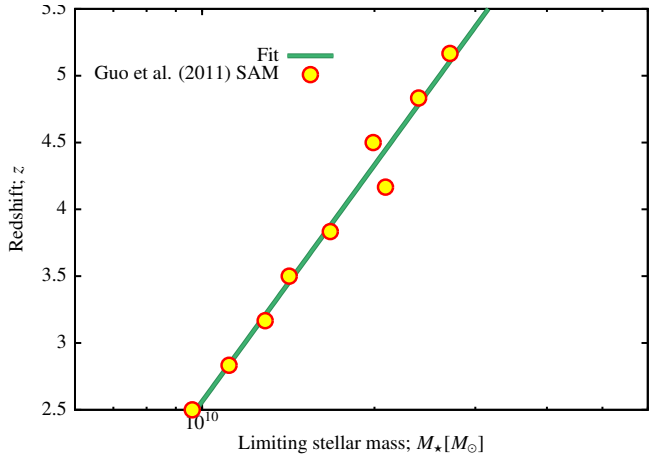

Figure 9.3.: The maximum redshift at which a galaxy of given stellar mass can be detected in the sample of Caputi et al. [2011]. Points show the results obtained using the Henriques et al. [2012] model from the Millennium Database, while the lines shows a polynomial fit to these results (given in eqn. 9.36).

where $x(M) = (n\sqrt{mu} - fM)/(\mu + fM)^{1/2}$. Given $f(M_{50}) = 0.5$ and $f(M_{80}) = 0.8$ we can solve for f and μ, and then compute the completeness in each mass using eqn. (9.37). The resulting completeness curves are shown in Fig. 9.5.3. Note that the model of eqn. (9.37) is clearly an oversimplification, but should capture the expected behavior of the completeness and, since it is fit to the 50% and 80% completenesses reported by Caputi et al. [2011]—which were computed using detailed simulations—should work sufficiently well.

Bernardi et al. (2013) SDSS Stellar Mass Function

This constraint utilizes the stellar mass function for $z \approx 0.07$ galaxies measured by Bernardi et al. [2013] from the SDSS survey. The mass function, and its covariance matrix $\mathbf{C}_{\rm model}$, is calculated as described in §4.4.1, typically on-the-fly as GALACTICUS is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.38}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta \mathbf{C}^{-1} \Delta\right], \tag{9.39}$$

where $\Delta_i = \Phi_{{\rm model},i} - \Phi_{{\rm observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

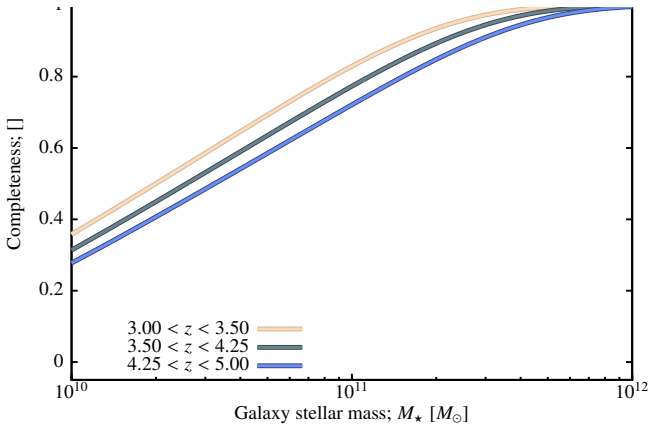

Figure 9.4.: The completeness as a function of stellar mass in the survey of Caputi et al. [2011]. Curves are computed using eqn. (9.37) with parameters fit to the reported 50% and 80% completeness masses from Caputi et al. [2011].

When computing the Poisson term in the covariance matrix, the number of galaxies per bin is determined directly from the mass function, assuming a 91% completeness[8]. The survey geometry and depth is described in §12.59.2.

Baldry et al. (2012) GAMA Stellar Mass Function

This constraint utilizes the stellar mass function for $z < 0.06$ galaxies measured by Baldry et al. [2012] from the GAMA survey. The mass function, and its covariance matrix $\mathbf{C}_{\rm model}$, is calculated as described in §4.4.1, typically on-the-fly as GALACTICUS is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.40}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta \mathbf{C}^{-1} \Delta\right], \tag{9.41}$$

where $\Delta_i = \Phi_{{\rm model},i} - \Phi_{{\rm observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

When computing the Poisson term in the covariance matrix, the number of galaxies per bin is taken from data supplied by I. Baldry (private communication). The survey geometry and depth is described in §12.59.5.

[8] 7% arising from fiber collisions, 2% from failures in the Pymorph pipeline (M. Bernardi, private communication).

Finally, the completeness of the observational sample is estimated to be greater than 98% (P. Norberg, private communication). Therefore we add an additional contribution to the observed covariance matrix equal to $\mathcal{C}_{ij} = 0.02\phi_i\phi_j$ where ϕ is the observed mass function.

Tomczak et al. (2014) ZFOURGE Stellar Mass Functions

This constraint utilizes the stellar mass function for $0.2 < z < 3$ galaxies measured by Tomczak et al. [2014] from the ZFOURGE survey. The mass function, and its covariance matrix $\mathbf{C}_{\rm model}$, is calculated as described in §4.4.1, typically on-the-fly as Galacticus is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.42}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta\mathbf{C}^{-1}\Delta\right], \tag{9.43}$$

where $\Delta_i = \Phi_{{\rm model},i} - \Phi_{{\rm observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

When computing the Poisson term in the covariance matrix, the number of galaxies per bin is taken directly from tables provided by R. Quadri (private communication).

Davidzon et al. (2013) VIPERS Stellar Mass Functions

This constraint utilizes the stellar mass function for $0.5 < z < 1.0$ galaxies measured by Davidzon et al. [2013] from the VIPERS survey. The mass function, and its covariance matrix $\mathbf{C}_{\rm model}$, is calculated as described in §4.4.1, typically on-the-fly as Galacticus is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.44}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta\mathbf{C}^{-1}\Delta\right], \tag{9.45}$$

where $\Delta_i = \Phi_{{\rm model},i} - \Phi_{{\rm observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

When computing the Poisson term in the covariance matrix, the number of galaxies per bin is taken directly from tables supplied by I. Davidzon (private communication).

Muzzin et al. (2013) ULTRAVISTA Stellar Mass Functions

This constraint utilizes the stellar mass function for $0.2 < z < 4.0$ galaxies measured by Muzzin et al. [2013] from the ULTRAVISTA survey. The mass function, and its covariance matrix $\mathbf{C}_\mathrm{model}$, is calculated as described in §4.4.1, typically on-the-fly as GALACTICUS is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_\mathrm{obs} + \mathbf{C}_\mathrm{model,random} + \sum_i \mathbf{C}_\mathrm{discrepancy},i, \tag{9.46}$$

where $\mathbf{C}_\mathrm{obs}$ is the covariance matrix of the observational data, $\mathbf{C}_\mathrm{model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_\mathrm{discrepancy},i$ is the covariance due to the i^th model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta \mathbf{C}^{-1} \Delta\right], \tag{9.47}$$

where $\Delta_i = \Phi_\mathrm{model},i - \Phi_\mathrm{observed},i$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

When computing the Poisson term in the covariance matrix, the completeness is taken to be 95% in the lowest mass bins, and 100% in all other bins [Muzzin et al., 2013].

Moustakas et al. (2013) PRIMUS Stellar Mass Functions

This constraint utilizes the stellar mass functions for $z \approx 0.2$ to $z \approx 1$ galaxies measured by Moustakas et al. [2013] from the PRIMUS survey. The mass functions, and their covariance matrices $\mathbf{C}_\mathrm{model}$, are calculated as described in §4.4.1, typically on-the-fly as GALACTICUS is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_\mathrm{obs} + \mathbf{C}_\mathrm{model,random} + \sum_i \mathbf{C}_\mathrm{discrepancy},i, \tag{9.48}$$

where $\mathbf{C}_\mathrm{obs}$ is the covariance matrix of the observational data, $\mathbf{C}_\mathrm{model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_\mathrm{discrepancy},i$ is the covariance due to the i^th model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta \mathbf{C}^{-1} \Delta\right], \tag{9.49}$$

where $\Delta_i = \Phi_\mathrm{model},i - \Phi_\mathrm{observed},i$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

When computing the Poisson term in the covariance matrix, the number of galaxies per bin is taken directly from Moustakas et al. [2013]. The survey geometry and depth is described in §12.59.6.

Martin et al. (2010) ALFALFA HI Mass Function

This constraint utilizes the HI mass function for $z \approx 0.0$ galaxies measured by Martin et al. [2010] from the ALFALFA survey. The mass function, and its covariance matrix $\mathbf{C}_{\rm model}$, is calculated as described in §4.4.1, typically on-the-fly as Galacticus is run. If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.50}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta \mathbf{C}^{-1} \Delta\right], \tag{9.51}$$

where $\Delta_i = \Phi_{{\rm model},i} - \Phi_{{\rm observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

When computing the Poisson term in the covariance matrix, the number of galaxies per bin is taken directly from Fig. 5 of Martin et al. [2010] such that incompleteness is automatically accounted for. The survey geometry and depth is described in §12.59.8.

The resulting maximum likelihood mass function is shown in Fig. 9.5, clearly illustrating that this parametric HOD can produce an excellent match to the observed mass function. The resulting correlation matrix is shown in Fig. 9.6. As expected, at the higher masses the correlation matrix is dominated by the on-diagonal terms—arising from the Poisson fluctuations in the number of galaxies due to the scarcity of these massive systems. At lower masses the matrix has significant off-diagonal amplitude, indicating strong correlations between nearby bins, arising from both large-scale structure and halo contributions to the covariance. This structure significantly weakens the constraint arising from the low-mass end of the mass function.

Shen et al. (2003) Late-Type Galaxy Size Distribution

This constraint utilizes the distribution of Petrosian half-light radii for $z \approx 0.07$ late-type galaxies measured by Shen et al. [2003] from the SDSS. The size function reported by Shen et al. [2003] is converted to the appropriate cosmology for the given Galacticus model (assuming that sizes scale as the angular diameter distance, and masses as the square of the luminosity distance).

Given a Galacticus model, total stellar masses of model galaxies are adjusted using:

$$M_\star \rightarrow \mathbf{GS} M_\star \tag{9.52}$$

where the $\mathbf{S}$ operator is a multiplicative factor accounting for systematic errors in stellar mass determination and is equal to [Behroozi et al., 2010]

$$\log_{10} S = \mu + \kappa \log_{10}\left(\frac{M_\star}{10^{11.0} M_\odot}\right) \tag{9.53}$$

where $\mu =$ `[diskGalaxySizesSDSSZ0.07MassSystematic0]`, $\kappa =$ `[diskGalaxySizesSDSSZ0.07MassSystematic1]`, and the $\mathbf{G}$ operator is a multiplicative factor drawn from a log-normal distribution of width 0.0806 dex

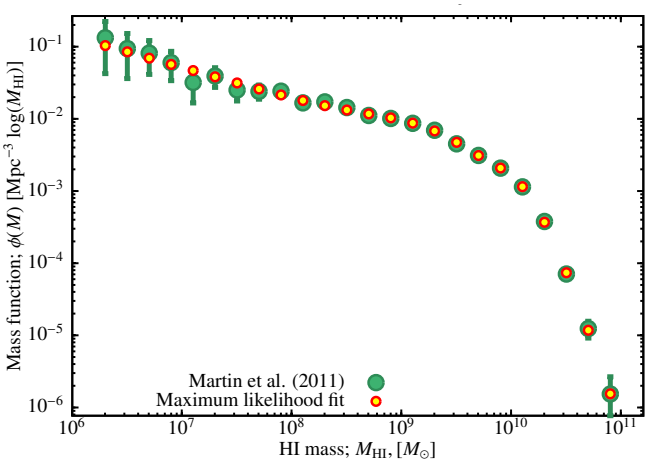

Figure 9.5.: The maximum likelihood mass function obtained from our parametric HOD (yellow points), compared to the observed HI mass function of Martin et al. (2010; green points).

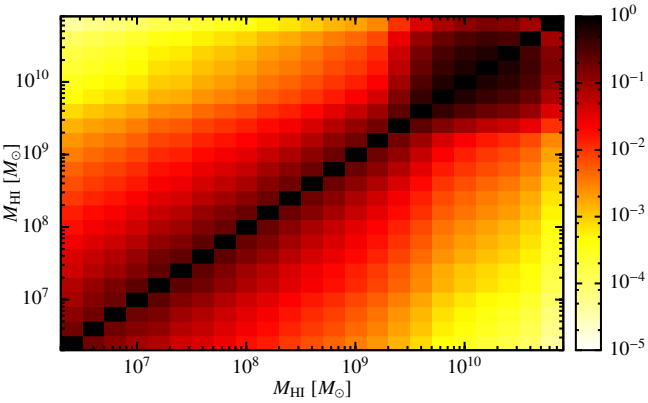

Figure 9.6.: The correlation matrix of the observed galaxy HI mass function of Martin et al. [2010]. Color indicates the strength of correlation between bins, according to the scale shown on the right.

for each galaxy to mimic the effects of random errors on stellar masses (motivated by the statement from Shen et al. [2003] who quote the 95% confidence interval on masses as being ±40%).

Note: This analysis currently assumes that model galaxies have disk Petrosian half-mass radii of

$$R_{50} = 1.6676 \frac{1}{\sqrt{2}} \lambda R_{\rm vir}. \tag{9.54}$$

Disk sizes of model galaxies are then adjusted using:

$$R_{50} \rightarrow \mathbf{G}\mathbf{S} R_{50} \tag{9.55}$$

where the $\mathbf{S}$ operator is a multiplicative factor accounting for systematic errors in radius determination and in determination of radius from halo virial radius and spin and is equal to

$$\log_{10} S = \mu + \kappa \log_{10} \left(\frac{R_{50}}{1 \mathrm{kpc}} \right) \tag{9.56}$$

where $\mu =$ `[iskGalaxySizesSDSSZ0.07RadiusSystematic0]`, $\kappa =$ `[iskGalaxySizesSDSSZ0.07RadiusSystematic1]`, and the $\mathbf{G}$ operator is a multiplicative factor drawn from a log-normal distribution of width 0.0128 dex for each galaxy to mimic the effects of random errors on disk radii (estimated from the fractional errors reported in the SDSS database).

The model sizes and masses are then used to construct a mass-dependent radius function by binning into a 2-D histogram using the size and mass bins reported by Shen et al. [2003] (modified as described above) as the centers of the bins (with bin boundaries placed at the geometric means of consecutive bin centers).

If the `-modelDiscrepancies` option is given, then any multiplicative or additive discrepancies found are applied to the model mass function, and any additional covariance is added to the covariance matrix.

The covariance matrix is computed as

$$\mathbf{C} = \mathbf{C}_{\rm obs} + \mathbf{C}_{\rm model,random} + \sum_i \mathbf{C}_{{\rm discrepancy},i}, \tag{9.57}$$

where $\mathbf{C}_{\rm obs}$ is the covariance matrix of the observational data, $\mathbf{C}_{\rm model,random}$ is the covariance matrix of the model arising from random noise (due to the finite number of trees simulated, and $\mathbf{C}_{{\rm discrepancy},i}$ is the covariance due to the $i^{\rm th}$ model discrepancy.

The model covariance matrix is estimated using the sample methods as described in §9.5.3. The only difference is that in this case we have a 2-D histogram. This 2-D histogram is "flattened" into a 1-D vector for purposes of likelihood computation however, so covariance matrix estimation proceeds unchanged. (Note that correlations between mass bins are accounted for, in additional to correlations between radius bins.) Since the radius functions of Shen et al. [2003] are normalized to unity at each mass, we must account for this in the covariance matrix. The radius function transforms as:

$$f_{ik} \rightarrow \frac{f_{ik}}{\Delta \log_{10} R \sum_i f_{ik}}, \tag{9.58}$$

where i indexes radius bins, k indexes mass bins, and $\Delta \log_{10} R$ is the width of the radius bin. The Jacobian of this transformation is simply

$$J_{ij} = \frac{\delta_{ij} - f_i}{\Delta \log_{10} R \sum_i f_{ik}}. \tag{9.59}$$

Therefore, the covariance matrix is modified according to $\mathcal{C} \rightarrow J \mathcal{C} J^{\rm T}$. The same transformation is applied to the covariance matrix of the observed data (for which the reported errors are simply the Poisson errors on each bin).

The model likelihood is then computed using:

$$\mathcal{L} = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} \exp\left[-\frac{1}{2}\Delta\mathbf{C}^{-1}\Delta\right], \tag{9.60}$$

where $\Delta_i = \Phi_{\mathrm{model},i} - \Phi_{\mathrm{observed},i}$ is the difference between the model and observed mass functions, and n is the number of points in the mass function histogram.

9.6. Constraint Compilations

To specify which constraints will be applied to a particular model, a compilation file is used. These must be stored in `constraints/compilations`. An example of such a file follows:

```
<constraintCompilation>
  <constraint>
    <definition>constraints/constraints/stellarMassFunction_SDSS_z0.07.xml</definition>
    <weight>1.0</weight>
  </constraint>
  <constraint>
    <definition>constraints/constraints/hiMassFunction_ALFALFA_z0.00.xml</definition>
    <weight>1.0</weight>
  </constraint>
</constraintCompilation>
```

Each `constraint` element specifies one constraint that will be included in this compilation, and must contain a `definition` element, giving the path of the configuration file for this constraint, and a `weight` element which allows the relative weight given to each constraint to be varied[9].

9.7. Constraint File

Galacticus has a complete constraints infrastructure which implements various MCMC algorithms to analyze the posterior probability distribution of the model given some compilation of constraints. The infrastructure is message passing interface (MPI) parallelized and ideal for running on large compute clusters.

To perform a constraint calculation simply build the constraint code:

```
make Constrain_Galacticus.exe
```

and run with a parameter file and configuration file. Typically, you will want to run this code under MPI, for example:

```
mpirun -n 4 Constrain_Galacticus.exe mcmcParameters.xml mcmcConfig.xml
```

would run 4 processes (typically you will need to run many more than this). If running on a portable batch system (PBS) queue, embed this command in a suitable PBS script and submit.

The parameter file follows the same format as a standard Galacticus parameter file and specifies the values of parameters to be used. For example, the seed used fo pseudo-random number sequences can be specified in this file.

The configuration file specifies the details of the constraint simulation to be performed. An example configuration file is:

[9] Note that, if your constraints are computing correct likelihoods, re-weighting them may not be a good idea. *Caveat constrainor.*

```

The following subsections describe each entry in this file.

9.7.1. likelihood

The likelihood section specifies the likelihood function to be used in the simulation. The type of likelihood to use is specified by the type element. The available choices are described in the following subsections.

multivariateNormal

The likelihood is a simple multivariate Gaussian, intended primarily for testing purposes. The distribution parameters are specified within the likelihood element using:

```
<mean>0.45 0.50</mean>
<covariance>
  <row>1.0e-4 -0.9e-4</row>
  <row>-0.9e-4 1.0e-4</row>
</covariance>
```

where the mean element gives the mean vector of N elements, and the covariance element contains N row elements each containing a vector of N elements giving a single row of the covariance matrix. The likelihood is then:

$$\log \mathcal{L} = -\frac{1}{2}\Delta\mathcal{C}^{-1}\Delta^{\mathrm{T}}, \tag{9.61}$$

where $Delta = \theta - \bar{\theta}$, θ is the state, $\bar{\theta}$ is the mean, and $\mathcal{C}$ is the covariance matrix.

multivariateNormalStochastic

The likelihood is identical to that of the multivariateNormal class, except that the likelihood function is evaluated stochastically. In addition to the parameter of the multivariateNormal class, two additional parameters are required and are specified within the likelihood element using:

```
<realizationCount>4000</realizationCount>
<realizationCountMinimum>10</realizationCountMinimum>
```

When evaluating the likelihood, the state vector is set equal to

$$S_i' = \sum_{j=1}^{N} \frac{2U(S_i)}{N}, \tag{9.62}$$

where $N =$realizationCount and $U(x)$ is a uniform random deviate in the range 0 to x. This results in a variance in S_i' of $S_i^2/3N$. This variance is added to the covariance used in evaluating the likelihood. When evaluating the likelihood at a higher temperature the number of realizations is reduced (which increases the covariance, which has the same effect as increasing the temperature) to speed computation, and the likelihood corrected for this fact. The number of realizations is reduced to N/T, but never allowed to fall below realizationCountMinimum.

Galacticus

The likelihood is computed by running and analyzing a Galacticus model. The details of the model to run are specified by the follow content within the `likelihood` element:

```
<name>verySimplisticToStellarMassFunction</name>
<compilation>stellarMassFunction_SDSS_z0.07.xml</compilation>
<baseParameters>./mcmcWork/verySimplisticToStellarMassFunctionBase.xml</baseParameters>
<workDirectory>./mcmcWork</workDirectory>
<scratchDirectory>./mcmcScratch</scratchDirectory>
<report>no</report>
<randomize>no</randomize>
<threads>4</threads>
<saveState>no</saveState>
<cpulimit>1200</cpulimit>
<memoryLimit>2gb</memoryLimit>
<environment>LD_LIBRARY_PATH=/opt/gcc-trunk/lib:/opt/gcc-trunk/lib64:/usr/local/upstream/lib:$LD_LIBRA
<environment>PATH=/opt/gcc-trunk/bin:$PATH</environment>
<environment>GFORTRAN_ERROR_DUMPCORE=NO</environment>
<treesPerDecadeMinimum></treesPerDecadeMinimum>
```

The entries have the following meanings:

`name` A name to use for this calculation. It will be used as the name for jobs submitted to the PBS queue for example.

`compilation` Specifies the compilation file to be used for this analysis.

`baseParameters` Specifies the path to a Galacticus parameter file which will be used as the base set of parameter on top of which any parameter variations will be applied.

`report` If set to `yes`, reports additional debugging information during the run.

`scratchDirectory` The full path to a scratch directory where Galacticus model outputs and other temporary data will be written.

`memoryLimit` A memory limit to be passed to PBS.

`randomize` If `yes` then each model evaluation will be performed with a different random number seed. Otherwise, the same seed is used in all cases. Experiment shows that changing the random number seed between evaluations can seriously limit the ability of MCMC algorithms to converge.

`threads` The number of parallel OpenMP threads to use for each Galacticus model. It is recommended that this be set to the number of available cores on each node, and semaphoring (see §sec:Semaphores) be used. In this way, each copy of Galacticus on a node will share resources, but as one instance finishes, the others will be able to make use of the freed resources.

`coredump` If present, this value will be assigned to the environment variable `GFORTAN_ERROR_DUMPCORE` to allow core dumps on error conditions to be switched on or off.

`coredumpsize` If present, limit the size of core dumps to this value (a value of `unlimited` allows for unlimited size core dumps.

`sequentialModels` If set to `yes` the Galacticus models are run sequentially on each node, rather than all at once.

`saveState` If `yes` then GALACTICUS will save its internal state prior to beginning evolution of each merger tree. This is intended for debugging purposes and so should normally be set to `no`.

`threads` The total number of threads (i.e. parallel chains) to use.

`environment` One of more such element can appear. Each specifies the value of an environment variable to be set prior to launching the GALACTICUS model.

`useFixedTrees` If set to `yes`, then a fixed set of merger trees are used for all model evaluations. This fixed set is generated automatically as needed[10], using the base parameters.

`fixedTreesInScratch` If set to `yes`, any fixed set of merger trees generated will be stored in the scratch directory, otherwise they will be stored in the work directory. (Storing in scratch can often be faster, particularly if `/dev/shm` is used as scratch, but for large sets of trees the available scratch storage space may be insufficient.)

When evaluating model likelihood at temperatures above unity, GALACTICUS will attempt to speed computation by reducing the number of trees simulated. Specifically, it makes use of the facts that the model covariance, $\mathcal{C} \propto N_\mathrm{tree}^{-1}$, and that the model log-likelihood, $\mathcal{L} \propto \mathcal{C}^{-1}/T$. Therefore, increasing the temperature is equivalent to decreasing the number of trees simulated by the same proportion. GALACTICUS therefore runs a simulation with a number of trees per decade of halo mass equal to `int([mergerTreeBuildTreesPerDecade]/T)` or the value of the `treesPerDecadeMinimum` element, whichever is smaller. This defines an effective temperature $T' = N'_\mathrm{trees}/N_\mathrm{trees}$ where N_trees is the original number of trees per decade, and N'_trees is the reduced number.

The model likelihood, $\mathcal{L}'$ is then evaluated using this reduced number of trees. The covariance matrix of the data is increased by a factor T' when evaluating the likelihood, as are any additions to the covariance due to model discrepancy. Finally, the likelihood at $T = 1$ is computed using:

$$\log \mathcal{L} = T' \log \mathcal{L}' + (T' - 1) \left[\frac{N}{2} \log 2\pi + \frac{1}{2} \log |\mathcal{C}'| \right], \tag{9.63}$$

where N is the dimension of the covariance matrix and $\mathcal{C}'$ is the full covariance matrix.

gaussianRegression

The likelihood is computed either using another likelihood function (the "simulator") or via Gaussian regression emulation of that simulator. The details of the emulation algorithm are specified by the follow content within the `likelihood` element:

```
<emulatorRebuildCount>100</emulatorRebuildCount>
<polynomialOrder>2</polynomialOrder>
<sigmaBuffer>3.0</sigmaBuffer>
<logLikelihoodBuffer>10.0</logLikelihoodBuffer>
<logLikelihoodErrorTolerance>0.01</logLikelihoodErrorTolerance>
<reportCount>100</reportCount>
<simulatorLikelihood>
 .
 .
 .
</simulatorLikelihood>
```

[10] If the temperature is being varied the number of trees per decade of halo mass changes throughout the simulation. In this case, a new set of trees is generated for each distinct value of the numbers of trees per decade.

The entries have the following meanings:

`emulatorRebuildCount` The number of simulator evaluations from which the emulator is built;

`polynomialOrder` The order of the polynomial fitted to the simulator likelihoods prior to Gaussian regression;

`sigmaBuffer` See below;

`logLikelihoodBuffer` See below;

`logLikelihoodErrorTolerance` See below;

`reportCount` The number of likelihood evaluations between successive reports on the status of the emulator;

`emulateOutliers` If true, then outlier chains are always emulated post-convergence (this is safe if such chains are not used in constructing proposals for non-outlier chains);

`simulatorLikelihood` Contains another likelihood function definition which will be used to construct the simulator.

In detail, this likelihood function first collects `emulatorRebuildCount` likelihood evaluations from the simulator. It then fits a polynomial of order `polynomialOrder` and of dimension equal to the dimension of the state vector to the simulated likelihoods. Gaussian regression is performed on the residuals of the simulated likelihoods after this polynomial fit is removed. Once the emulator has been built in this way every second simulated state is discarded, and accumulation of new simulated states continues. Once `emulatorRebuildCount` simulated states have once again been accumulated a new simulator is built. This ensures that the emulator does not lose all information used in building the previous emulator[11], instead information from older emulators decays exponentially.

Once an emulator has been built, on each successive likelihood evaluation the emulated log-likelihood $\log \mathcal{L}_\mathrm{e}$ and its error estimate $\sigma_{\log \mathcal{L}_\mathrm{e}}$ are computed. The emulated likelihood is then returned if:

$$\log \mathcal{P}' + \log \mathcal{L}_\mathrm{e} + N \sigma_{\log \mathcal{L}_\mathrm{e}} < \log \mathcal{P} + \log \mathcal{L} - T \Delta \log \mathcal{L}, \tag{9.64}$$

where $N =$`sigmaBuffer`, $\Delta \log \mathcal{L} =$`logLikelihoodBuffer`, T is the temperature, $\log \mathcal{L}$ is the current log-likelihood, $\log \mathcal{P}$ is the current log-prior probability, and $\log \mathcal{P}'$ is the proposed log-prior probability, or if

$$\sigma_{\log \mathcal{L}_\mathrm{e}} < T \sigma_{\log \mathcal{L}}, \tag{9.65}$$

where $\sigma_{\log \mathcal{L}} =$`logLikelihoodErrorTolerance`, otherwise the simulator is used to compute the exact likelihood. In this way, the emulated likelihood is used if it is sufficiently below the current likelihood that, even accounting for the emulation error, transition to the new state is highly unlikely, or if the error on the likelihood emulation is sufficiently small that it will not have a significant effect on the transition probabilty to the proposed state.

If verbosity is set to 2 or greater than a report will be issued every `reportCount` evaluations. The report will give the proportions of simulated vs. emulated evaluations. Additionally, during the evaluation where the report is issued, both the emulated and simulated log-likelihoods are evaluated and are tested to see if they lie within $3\sigma_{\log \mathcal{L}_\mathrm{e}}$ of each other. The rate of failures (i.e. where the two differ by more than this amount) is then reported.

[11] This would be unfortunate as the second emulator to be built would then contain information on only those regions of the state space that were poorly emulated before.

posteriorPrior

The likelihood is computed either using another likelihood function (the "wrapped" likelihood), while including in the likelihood an esimate of the posterior probability of a previous simulation. This effectively allows the posterior of the previous simulation to be used as a prior on the current simulation. The details of the likelihood are specified by the follow content within the `likelihood` element:

```
<chainBaseName>./oldChains</chainBaseName>
<neighborCount>32</neighborCount>
<tolerance>1.0e-3</tolerance>
<wrappedLikelihood>
 .
 .
 .
</wrappedLikelihood>
```

The entries have the following meanings:

`chainBaseName` The base name for the old set of MCMC chains to use as the new prior;

`neighborCount` The number of neighbor points to use in kernel density estimation of the posterior probability;

`tolerance` Tolerance used in finding nearest neighbors;

`wrappedLikelihood` Contains another likelihood function definition which will be used to provide the current likelihood.

This method uses the Approximate Nearest Neighbor library to locate `neightborCount` nearest neighbor points in the set of converged states found in the given chains. The `tolerance` element determines the accuracy of nearest neighbor finding (see the Approximate Nearest Neighbor documentation for details).When finding nearest neighbors in the MCMC chains, parameters are mapped using whatever mappings are currently active, and distances in each dimension (as used in the metric to determine nearest neighbors) are scaled by the root-variance in that parameter in the converged MCMC chains. The posterior likelihood of the MCMC chains is then estimated from the nearest neighbors using kernel density estimation with a Gaussian kernel with bandwidth equal to the distance to the furthest of the nearest neighbors.

massFunction

The likelihood is computed as

$$\log \mathcal{L} = -\frac{1}{2}\Delta \cdot \mathcal{C}^{-1} \cdot \Delta^{\mathrm{T}}, \tag{9.66}$$

where $\mathcal{C}$ is the covariance matrix, and $\Delta_i = w_i^{\mathrm{model}} - w_i^{\mathrm{obs}}$, w_i^{model} is the computed mass function at the i^{th} separation, and w_i^{obs} is the observed mass function at the i^{th} separation. The mass function is computed using the halo model and the parameterized conditional galaxy mass function of [Behroozi et al., 2010, see also Leauthaud et al. [2011]; §12.8.1]. The details of the mass function calculation are specified by the follow content within the `likelihood` element:

```
<haloMassMinimum>1.0e9</haloMassMinimum>
<haloMassMaximum>1.0e15</haloMassMaximum>
<redshiftMinimum>0.0</redshiftMinimum>
<redshiftMaximum>0.5</redshiftMaximum>
<massFunctionFileName>projectedCorrelation.hdf5</massFunctionFileName>
```

The entries have the following meanings:

`haloMass(Min|Max)imum` The minimum/maximum halo mass over which to integrate in the halo model;

`redshift(Min|Max)imum` The minimum/maximum redshift over which to integrate in the halo model;

`massFunctionFileName` The name of an HDF5 file containing the observed mass function and its covariance matrix.

The HDF5 file specified by the `massFunctionFileName` element should contain a `mass` dataset, giving the masses at which the mass function is measured (in units of $M_\odot$), a `massFunctionObserved` dataset giving the observed values of the mass function at those masses (in units of Mpc^{-3} per $\log M$), and a `covariance` dataset, giving the covariance of the mass function (in units of Mpc^{-6}).

projectedCorrelationFunction

The likelihood is computed as

$$\log \mathcal{L} = -\frac{1}{2} \Delta \cdot \mathcal{C}^{-1} \cdot \Delta^{\mathrm{T}}, \tag{9.67}$$

where $\mathcal{C}$ is the covariance matrix, and $\Delta_i = w_i^{\mathrm{model}} - w_i^{\mathrm{obs}}$, w_i^{model} is the computed projected correlation function at the i^{th} separation, and w_i^{obs} is the observed projected correlation function at the i^{th} separation. The projected correlation function is computed using the halo model and the parameterized conditional galaxy mass function of [Behroozi et al., 2010, see also Leauthaud et al. [2011]; §12.8.1]. The details of the projected correlation function calculation are specified by the follow content within the `likelihood` element:

```
<haloMassMinimum>1.0e9</haloMassMinimum>
<haloMassMaximum>1.0e15</haloMassMaximum>
<redshiftMinimum>0.0</redshiftMinimum>
<redshiftMaximum>0.5</redshiftMaximum>
<projectedCorrelationFunctionFileName>projectedCorrelation.hdf5</projectedCorrelationFunctionFileName>
```

The entries have the following meanings:

`haloMass(Min|Max)imum` The minimum/maximum halo mass over which to integrate in the halo model;

`redshift(Min|Max)imum` The minimum/maximum redshift over which to integrate in the halo model;

`projectedCorrelationFunctionFileName` The name of an HDF5 file containing the observed projected correlation function and its covariance matrix.

The HDF5 file specified by the `projectedCorrelationFunctionFileName` element should contain a `separation` dataset, giving the spearations at which the projected correlation function is measured (in units of Mpc), a `projectedCorrelationFunctionObserved` dataset giving the observed values of the projected correlation function at those separations (in units of Mpc), and a `covariance` dataset, giving the covariance of the projected correlation function (in units of Mpc^2).

9.7.2. convergence

The `convergence` section specifies the criterion to be used to judge when the simulation has converged. The type of convergence criterion to use is specified by the `type` element. The available choices are described in the following subsections.

`never`

This option assumes that the simulation never converges, and so the calculation will run indefinitely. It is intended primarily for testing purposes.

`GelmanRubin`

This option adopts the convergence criterion proposed by Gelman and Rubin (1992; see also Brooks and Gelman 1998), which compares the variance in parameter values within chains to that between chains. Outlier detection is applied to the chains using a standard Grubb's outlier test. The behavior of this criterion is controlled by the following options which should be placed within the `convergence` element:

`Rhat` The correlation coefficient, $\hat{R}$, value at which to declare convergence.

`burnCount` Set number of steps to burn before applying the convergence test.

`testCount` Set the number of steps between successive applications of the convergence test.

`outlierSignificance` The significance level required in outlier detection.

`outlierLogLikelihoodOffset` The offset in log-likelihood from the current maximum likelihood chain required for a chain to be declared to be an outlier.

`outlierCountMaximum` The maximum number of outlier chains allowed.

9.7.3. `state`

The `state` section specifies the type of object used to record the state of the simulation. The type of state object to use is specified by the `type` element. The available choices are described in the following subsections.

`simple`

This type stores the current state but makes no attempt to record a history of the state and so cannot provide measures of the mean or variance of state over the simulation history. It does, however, maintain a running average of the state acceptance rate. The number of steps over which the acceptance rate should be computed is specified by the `acceptedStateCount`.

`history`

An extension of the `simple` state, this type also records the mean and variance of each parameter over the history of the simulation.

`correlation`

An extension of the `history` state, this type also computes and stores the correlation length in each parameter (which is taken to be the median correlation length over all non-outlier chains).

9.7.4. `stoppingCriterion`

The `stoppingCriterion` section specifies the type of object used to determine when the simulation should be stopped. The type of stopping criterion object to use is specified by the `type` element. The available choices are described in the following subsections.

`never`

This type will cause the simulation to never stop.

`stepCount`

This type will cause the simulation to stop when at least a number of steps (as specified in the `stopAfterCunt` element) have accrued post-convergence.

`correlationLengthCount`

This type will cause the simulation to stop when at least a number of correlation lengths (as specified in the `stopAfterCunt` element) have accrued post-convergence.

9.7.5. `stateInitializor`

The `stateInitializor` section specifies the type of object used to initialize the state of chains at the beginning of the simulation. The type of state initializor object to use is specified by the `type` element. The available choices are described in the following subsections.

`priorRandom`

This type simply draws a random state vector from the prior distributions of the parameters.

`resume`

This type resumes from a previous simulation by setting the chain states to the states at the end of that simulation. The `logFileRoot` element is used to specify the log-file root name used in the previous simulation.

`latinHypercube`

This type uses a Latin hypercube design (in the cumulative probability distribution of each parameter) to assign initial state vectors. In particular, a maximin design is used in which a number of trial Latin hypercubes are constructed and the hypercube with the greatest minimum distance between any pair of state vectors is selected. The `maximinTrialCount` element is used to specify the number of trial hypercubes to construct.

9.7.6. `proposalSize`

The `proposalSize` section specifies the method to use when selecting the proposal size parameter, γ (the fraction of the vector connecting to chain state to be used as the proposal for another chain), for use in differential evolution simulations. The proposal size algorithm to use is specified by the `type` element. The available choices are described in the following subsections.

`fixed`

This option uses a fixed γ specified by the `gamma` element.

`adaptive`

This option adaptively changes γ in an attempt to maintain the acceptance rate at an acceptable level. The algorithm is controlled by the following parameters (to be specified as elements within the `proposalSize` element):

`gammaInitial` The initial value for γ.

`gammaFactor` The multiplicative factor by which γ should be increased or decreased if the acceptance rate is out of range.

`gammaMinimum` The smallest value allowed for γ.

`gammaMaximum` The largest value allowed for γ.

`acceptanceRateMinimum` The minimum acceptance rate to accept before reducing γ.

`acceptanceRateMaximum` The maximum acceptance rate to accept before reducing γ.

`updateCount` The number of steps between successive checks of the acceptance rate.

9.7.7. `proposalSizeTemperatureExponent`

The `proposalSizeTemperatureExponent` section specifies the method to use when selecting the exponent, α, for the temperature scaling of the proposal size parameter, γ (the fraction of the vector connecting to chain state to be used as the proposal for another chain), for use in tempered differential evolution simulations. The proposal size temperature exponent algorithm to use is specified by the `type` element. The available choices are described in the following subsections.

`fixed`

This option uses a fixed α specified by the `alpha` element.

`adaptive`

This option adaptively changes α in an attempt to maintain the gradient of the acceptance rate with the logarithm of temperature, $\mathrm{d}R/\mathrm{d}\ln T$, at an acceptable level. The algorithm is controlled by the following parameters (to be specified as elements within the `proposalSizeTemperatureExponent` element):

`exponentInitial` The initial value for α;

`exponentFactor` The additive factor by which α should be increased or decreased if the acceptance rate gradient is out of range;

`exponentMinimum` The smallest value allowed for α;

`exponentMaximum` The largest value allowed for α;

`acceptanceRateMinimum` The minimum acceptance rate gradient to accept before reducing α;

`acceptanceRateMaximum` The maximum acceptance rate gradient to accept before reducing α;

`updateCount` The number of steps between successive checks of the acceptance rate gradient.

9.7.8. randomJump

The `randomJump` section specifies the method to use when adding a random jump component to proposals in differential evolution simulations. The random jump algorithm to use is specified by the `type` element. The available choices are described in the following subsections.

simple

The random jumps are drawn directly from the distributions specified in the `random` element of each parameter (see §9.7.10).

adaptive

The random jumps are drawn from the distributions specified in the `random` element of each parameter (see §9.7.10) and then multiplied by the currently occupied range of each parameter (i.e. the maximum value of the parameter over all current chain states minus the minimum value of each parameter over all current chain states).

9.7.9. simulation

The `simulation` section specifies the algorithm to use to perform the simulation. The simulation algorithm to use is specified by the `type` element. The available choices are described in the following subsections.

differentialEvolution

This option uses the differential evolution algorithm of Terr Braak [2006]. Multiple, parallel chains are run and proposals are constructed by selecting two chains at random, taking a fraction, γ, of the vector connecting the two chain states and adding this to the state of the current chain. The details of the algorithm are controlled by the following elements which should be embedded within the `simulation` element:

`stepsMaximum` The maximum number of steps to take.

`acceptanceAverageCount` The number of steps over which to average the acceptance rate.

`stateSwapCount` The number of steps after which to set $\gamma = 1$ to allow chains to swap states.

`logFileRoot` The full path and root name of a file to log results to. The actual file name will have the rank of the MPI process appended to it.

`sampleOutliers` If set to `false` then proposals for non-outlier chains post-convergence are constructed only from other non-outlier chains. Otherwise, proposals for non-outleir chains post-convergence are constructed from all other chains.

simulatorStochasticDifferentialEvolution

This option extends the `differentialEvolution` option to run chains at a temperature matched to the uncertainty in the log-likelihood. This is designed to work with stochastic likelihood functions where an estimate of the uncertainty in the log-likelihood is available, and prevents the chains from becoming trapped in local maxima arising purely from random fluctuations. In addition to the options for the `differentialEvolution` algorithm, the details of the algorithm are controlled by the following elements whichy should be embedded within the `simulation` element:

`temperatureScale` The temperature scaling factor, *alpha*, described below.

In computing the acceptance probability for transitions between states, the chain temperature is set to

$$T = 1 + \alpha C \sqrt{\sigma^2_{\text{current}} + \sigma^2_{\text{proposed}}}, \tag{9.68}$$

where $C = \log(\hat{R}/\hat{R}_t)$, $\hat{R}$ is the current maximum (across all parameters) Gelman-Rubin convergence statistic, $\hat{R}_t$ is the target Gelman-Rubin convergence statistic at which convergence will be declared, and $\sigma^2_{\text{current}}$ and $\sigma^2_{\text{proposed}}$ are the variances in the log-likelihood of the current and proposed states respectively. This form ensures that the temperature declines to unity once the chains are converged (such that they will sample from the true posterior distribution), while ensuring that T is of order the size of the expected random fluctuations in the difference in log-likelihoods between states prior to chain convergence.

`temperedDifferentialEvolution`

This option extends the `differentialEvolution` option to include tempering during which the likelihood function is heated up and cooled down to allow chains to more easily walk through the likelihood landscape. In addition to the options for the `differentialEvolution` algorithm, the details of the algorithm are controlled by the following elements whichy should be embedded within the `simulation` element:

`untemperedStepCount` The number of untempered (i.e. $T = 1$) steps to take between tempering cycles.

`temperatureMaximum` The maximum temperature to use when tempering.

`temperedLevels` The number of tempered levels to use.

`stepsPerLevel` The number of differential evolution steps to take at each tempering level.

`logFlushCount` The number of steps after which the log file will be flushed to disk.

In each tempering cycle, the temperature is raised through levels $1 \ldots N$ (where $N =$`temperedLevels`), and then back down through levels $N - 1 \ldots 1$. The temperature at level i is given by:

$$\log T_i = \frac{i}{N} \log T_{\max}, \tag{9.69}$$

where $T_{\max} =$`temperatureMaximum`. During tempered steps, the γ parameter of the differential evolution algorithm is increased by a factor T^α, where α is provided by the `proposalSizeTemperatureExponent` class. A value of $\alpha = 1/2$ is optimal for a Gaussian likelihood.

`annealedDifferentialEvolution`

This option extends the `differentialEvolution` option to include an annealing schedule—the simulation begins at high temperature, waits for convergence, lowers the temperature and repeats until convergence at $T = 1$ is reached. In addition to the options for the `differentialEvolution` algorithm, the details of the algorithm are controlled by the following elements whichy should be embedded within the `simulation` element:

`temperatureMaximum` The maximum temperature to use when tempering.

`temperatureLevels` The number of temperature levels to use.

The temperature at level i is given by:

$$\log T_i = \frac{i-1}{N-1} \log T_{\max}, \tag{9.70}$$

where $T_{\max} =$`temperatureMaximum` and $N =$`temperatureLevels`.

9.7.10. Parameters and Priors

The `parameters` section contains a list of all parameters to be varied in the analysis. Each parameter is described by one `parameter` element. That element must contain a `name` element, which gives the name of the parameter, a `prior` element that contains a `distribution` element defining the distribution for this prior, a `mapping` element that describes the mapping of the parameter into the internal state used in MCMC calculations, and (for differential evolution simulations) a `random` element that defines the distribution to be used for the random perturbation to be added to this parameter in proposals.

The `name` element can specify subparameters, elements in an array of parameters, and elements within a parameter's `value` element. For example, consider the parameter file:

```
<parameter1 value="123"/>
<parameterA value="456"/>
<parameterA value="789"/>
<parameterA value="987"/>
<parameter2 value="abc">
 <parameter2a value="def"/>
</parameter2>
<parameterX value="1.0 2.0 3.0"/>
```

- A name of `parameter1` will change the value (`123`) of the `parameter1` element;
- A name of `parameterA[1]` will change the value (`1789`) of the second `parameterA` element (array indexing is 0-offset);
- A name of `parameter2->parameter2a` will change the value (`def`) of the `parameter2a` element;
- A name of `parameterX1` will change the value (`2.0`) of second entry in the value of the `parameterX` element.

Currently allowed mappings are:

`linear` Effectively a null mapping, as the parameter is mapped into itself: $x \rightarrow x$.

`logarithmic` The parameter is mapped logarithmically: $x \rightarrow \log(x)$. This mapping can be applied only to uniform priors.

Note that the mapping will map the values of the prior. For example, if you specify a uniform prior with a logarithmic mapping, the upper and lower limits of the prior should be specified on x, not on $\log(x)$. These limits will be mapped appropriately internally.

Loading External Parameters/Priors

It is also possible to load parameters and their priors from external files. This is useful to add common sets of parameters, such as cosmological parameter. To do so, add an element of the form:

```
<xi:include href="../../constraints/parameters/wmap9Cosmology.xml"
   xmlns:xi="http://www.w3.org/2001/XInclude" />
```

after the `parameters` section of the constraint file. The `href` attribute must give the path (relative to the constraint file, or absolute) to the external parameter file. This file should contain its own `parameters` block, describing all parameters to be varied along with their priors.

Derived Parameter Values

It is possible to define parameters in terms of other parameters. Common uses for this include:

- Setting Ω_Λ from the value of Ω_M to enforce a flat Universe;
- Setting the values of parameters with correlated priors as linear combinations of dummy parameters for which the priors are independent.

To define a parameter in this way include a `parameter` element of the form:

```
<parameter>
 <name>sigma_8</name>
 <define>0.8178+%cosmology0*0.003817+%cosmology1*0.007931+%cosmology2*0.01002
    +%cosmology3*0.001584+%cosmology4*0.002931+%cosmology5*0.001727</define>
</parameter>
```

Here the `define` element gives an equation for the parameter in terms of other parameters. All standard mathematical operators and functions (as recognized by Perl) can be used, and other parameters referenced by using their name prefixed with a "%".

Including External Parameters

Predefined sets of parameters (along with their priors) can be included using the `xi:include` element. For example,

```
 <xi:include href="../../constraints/parameters/wmap7Cosmology.xml"
    xmlns:xi="http://www.w3.org/2001/XInclude" />
```

will include a set of parameters from the file `../../constraints/parameters/wmap7Cosmology.xml` which defines priors on cosmological parameters consistent with the covariance matrix of the WMAP-7 cosmological constraints [Komatsu et al., 2010].

9.7.11. Distributions

Various distribution functions (for priors and random perturbations) are supported. Where needed, the type of distribution should be specified in a `type` element. Additional parameters of the distribution are specified using the elements described in the following subsections.

`uniform`

A uniform distribution over a finite range

$$P(x) \propto \begin{cases} 1 & \text{if } x_\mathrm{l} \leq x \leq x_\mathrm{u} \\ 0 & \text{otherwise.} \end{cases} \tag{9.71}$$

Specified using:

`minimum` The lower limit of the range, x_l;

`maximum` The upper limit of the range, x_u.

`logUniform`

A distribution uniform in the logarithm of x over a finite range

$$P(x) \propto \begin{cases} x^{-1} & \text{if } x_\mathrm{l} \leq x \leq x_\mathrm{u} \\ 0 & \text{otherwise.} \end{cases} \tag{9.72}$$

Specified using:

`minimum` The lower limit of the range, x_l;

`maximum` The upper limit of the range, x_u.

`normal`

A normal distribution, optionally with lower and upper limits:

$$P(x) \propto \begin{cases} \exp[-(x-\mu)^2/2S] & \text{if } x_\mathrm{l} \leq x \leq x_\mathrm{u} \\ 0 & \text{otherwise.} \end{cases} \tag{9.73}$$

Specified using:

`mean` The mean, μ;

`variance` The variance, S;

`minimum` The lower limit of the range, x_l;

`maximum` The upper limit of the range, x_u.

`Cauchy`

A Cauchy distribution:

$$P(x) \propto \left[1 + \frac{x - x_0}{\gamma}\right]^{-1}. \tag{9.74}$$

Specified using:

`median` The median, x_0;

`scale` The scale, γ;

`StudentT`

Student's t-distribution:

$$P(x) \propto \left(1 + \frac{x^2}{\nu}\right)^{-(\nu+1)/2} \tag{9.75}$$

Specified using:

`degreesOfFreedom` The number of degrees of freedom, ν.

Part III.

Physical Implementation

In this Part we describe the physical implementation of galaxy formation in Galacticus, including all components and their properties and additional output quantities from the code.

10. Definitions and Conventions Used in Galacticus

Galacticus adopts various definitions and conventions internally. These are explained below.

10.1. Halo Masses and Dark Matter Mass

Halo masses require some care in specifying exactly what mass they represent due to the way in which merger trees are typically created. For example, when merger trees are extracted from N-body simulations, those simulations frequently represent *all* matter as collisionless. That is, the simulation contains a density $\Omega_\mathrm{M} = \Omega_\mathrm{DM} + \Omega_\mathrm{b}$ which is the sum of dark and baryonic matter densities, but all of this mass is represented as collisionless particles. Similarly, masses in merger trees built through Monte Carlo techniques typically represent all mass as collisionless.

The exact way in which masses within Galacticus are defined and used in specified in the following subsections.

10.1.1. Masses in the Basic Component

The `basic` component (see §11.8) tracks the mass of each halo as defined in the merger tree. As such, it should be considered to be the mass which the halo would have if baryonic matter behaved just as dark matter. Note that these masses are inclusive of subhalos—that is, the mass of a host halo includes the mass of all of its subhalos.

10.1.2. Dark Matter Profiles

The dark matter profile functions (see §12.11.2) return masses and densities etc. which are normalized to match the mass of the `basic` component at the virial radius of the halo. As such, their returned values should be considered to represent the case where baryonic matter behaves as dark matter. This is a convention, and is useful for calculations of large scale structure for example.

10.1.3. Galactic Structure Functions

The various galactic structure functions assume that the masses/densities/etc. reported by the dark matter profile functions should be scaled by a factor $(\Omega_\mathrm{M} - \Omega_\mathrm{b})/\Omega_\mathrm{b}$ to leave only the dark matter part of the profile. Baryonic contributions to the mass/density/etc. will be provided by the components representing those mass distributions.

10.1.4. Satellite Virial Orbits

These functions (see §12.51.2) typically use the `basic` component mass in determining parameters of an orbit, since they are typically calibrated to simulations of collisionless matter only.

10.1.5. Satellite Merging Timescales

These functions (see §12.51.1) typically use the `basic` component mass in determining parameters of an orbit, since they are typically calibrated to simulations of collisionless matter only.

10.1.6. Dynamical Friction

These functions (see §12.41) evaluate densities through the relevant galactic structure function, and so correctly account for the fraction of the `basic` component mass which is in the form of dark matter.

10.1.7. Galactic Structure Radius Solvers

These functions §12.16) determine the radii of galactic components (such as disk and spheroid), typically by iteratively seeking a solution in which their angular momenta and radii are consistent (assuming rotational support) with the net gravitational potential of the entire system (galaxy plus dark matter halo).

10.2. Luminosity Units

Galaxy luminosities are output in the AB magnitude system, such that a luminosity of 1 corresponds to an object of $0^{\rm th}$ absolute magnitude in the AB magnitude system. This implies that the luminosities are in units of 4.4659×10^{13} W/Hz.

10.3. Peculiar Velocities

Velocities in Galacticus are always *physical* velocities. When reading merger tree properties (including velocities) from file it is often convenient to store velocities without the Hubble flow contribution, as "peculiar velocities", in the file—see §A.7 for how to specify whether or not the velocities included in the file include the Hubble flow or not.

If peculiar velocities are stored it is important to use the same definition of pecular velocity as is used by Galacticus. Defining t to be physical time and $\mathbf{x}$ to be comoving position, Galacticus uses the conventional definition of peculiar velocity in a cosmological context, namely that it is the deviation of the physical velocity from the Hubble flow. Physical coordinates are given by $\mathbf{r} = a\mathbf{x}$, so the peculiar velocity is

$$\mathbf{v}_{\rm pec} \equiv \frac{{\rm d}\mathbf{r}}{{\rm d}t} - H\mathbf{r} = a\frac{{\rm d}\mathbf{x}}{{\rm d}t} = \frac{{\rm d}\mathbf{x}}{{\rm d}\eta}, \tag{10.1}$$

where ${\rm d}\eta = {\rm d}t/a$ is conformal time.

10.4. Gravitational Potentials

Gravitational potentials are measured in velocity units (i.e. $\mathrm{km}^2/\mathrm{s}^2$), and the arbitrary constant offset is chosen such that the total gravitational potential in any halo at the virial radius is $\Phi(r_{\rm virial}) = -V^2_{\rm virial}$. This choice is made for two reasons:

1. some mass distributions used have potentials which diverge as $r \rightarrow \infty$, so the usual choice of $\Phi(r) \rightarrow 0$ as $r \rightarrow \infty$ is not applicable;

2. this choice is consistent with the potential at the virial radius of the halo considered as a point mass as is used in Keplerian orbit calculations.

Note that the choice of constant offset for the potential of any mass distribution or galactic component is irrelevant—the galactic structure function which computes potential will ensure that the potential is always offset to match the definition given above.

11. Node Components

In addition to the implementations described here, each component class has a "`null`" implementation. Selecting this implementation—which has no properties and does not respond to any events—effectively switches off the relevant component class. Of course, this is safe only if none of the other active implementations expect to get or set properties of the component class (or if they rely on a sensible implementation of that class).

11.1. (Supermassive) Black Hole

11.1.1. "Standard" Implementation

Properties

The standard black hole implementation defines the following properties:

`mass` The mass of the black hole: $M_\bullet$ `[blackHoleMass]`.

`spin` The spin of the black hole, $j_\bullet$ `[blackHoleSpin]`.

`radialPosition` The radial position of the black hole: $r_\bullet$ `[blackHoleRadialPosition]`

Initialization

Black holes are not initialized, they are created (with a seed mass given by `blackHoleSeedMass` and zero spin) as needed.

Differential Evolution

In the standard black implementation the mass and spin evolve as:

$$\dot{M}_\bullet = (1-\epsilon_{\rm radiation}-\epsilon_{\rm jet})\dot{M}_0 \quad (11.1)$$

$$\dot{j}_\bullet = \dot{j}(M_\bullet, j_\bullet, \dot{M}_0), \quad (11.2)$$

where $\dot{M}_0$ is the rest mass accretion rate, $\epsilon_{\rm radiation}$ is the radiative efficiency of the accretion flow feeding the black hole, $\epsilon_{\rm jet}$ is the efficiency with which accretion power is converted to jet power and $\dot{j}(M_\bullet, j_\bullet, \dot{M}_0)$ is the spin-up function of that accretion flow (see §16.4.1). The rest mass accretion rate is computed assuming Bondi-Hoyle-Lyttleton accretion from the spheroid gas reservoir (with an assumed temperature of `[bondiHoyleAccretionTemperatureSpheroid]`) enhanced by a factor of `[bondiHoyleAccretionEnhancementSpheroid]` and from the host halo (with whatever temperature that hot halo temperature profile specifies; see §12.27) enhanced by a factor of `[bondiHoyleAccretionEnhancementHotHalo]`. For accretion from the hot halo, the Bondi radius is limited to the outer radius of the hot halo. Additionally, the accretion rate is limited to:

$$\dot{M}_{0,\ \text{hot halo, maximum}} = M_{\rm hot}/\tau_{\text{sound crossing}}, \quad (11.3)$$

where $\tau_{\text{sound crossing}} = r_{\text{hot halo outer}}/c_{\rm s}$ where $r_{\text{hot halo outer}}$ is the outer radius of the hot halo and $c_{\rm s}$ is the speed of sound in the hot halo.

If `[bondiHoyleAccretionHotModeOnly]=true` then the accretion occurs only from that fraction of the hot halo gas which was accreted in the "hot mode", otherwise accretion occurs from the entirety of the hot halo reservoir. In the first case a simple estimate of the hot mode fraction is made:

$$f_\mathrm{hot} = \begin{cases} 1 & \text{if } x < 0.9 \\ y(x)^2[2y(x)-3]+1 & \text{if } 0.9 \leq x \leq 1.0 \\ 0 & \text{if } x > 1.0, \end{cases} \tag{11.4}$$

where $x = r_\mathrm{cool}/r_\mathrm{virial}$ and $y(x) = [x-0.9]/[1.0-0.9]$.

The rest mass accretion rate is removed (as a mass sink) from the spheroid and hot halo components appropriately. The black hole is assumed to cause feedback in two ways:

Radio-mode If `[blackHoleHeatsHotHalo]=true` then any jet power from the black hole-accretion disk system (see §12.5) is included in the hot halo heating rate providing that the halo is in the slow cooling regime[1] (i.e. if the cooling radius is smaller than the virial radius; see, for example, Benson and Bower 2010);

Quasar-mode A mechanical wind luminosity of [Ostriker et al., 2010]

$$L_\mathrm{wind} = \epsilon_{\bullet,\mathrm{wind}} H(\epsilon_\mathrm{radiation}, 1, s) \dot{M}_0 \mathrm{c}^2, \tag{11.5}$$

where $\epsilon_{\bullet\mathrm{wind}}$ =`[blackHoleWindEfficiency]` is the black hole wind efficiency, s=`blackHoleWindEfficiencyScalesWithRadiativeEfficiency`, and

$$H(a,b,c) = \begin{cases} a & \text{if } c = \texttt{true} \\ b & \text{if } c = \texttt{false}, \end{cases} \tag{11.6}$$

is added to the gas component of the spheroid (which, presumably, will respond with an outflow for example—see §11.5 for details of how specific implementations of the spheroid component respond to the addition of energy) if and only if the wind pressure (at the spheroid characteristic radius) is less than the typical thermal pressure in the spheroid gas [Ciotti et al., 2009], i.e.

$$\begin{aligned} P_\mathrm{wind} &< P_\mathrm{ISM} \\ \frac{1}{2}\rho_\mathrm{wind} V_\mathrm{wind}^2 &< \frac{3 \mathrm{k_B} T_\mathrm{ISM} \langle \rho_\mathrm{ISM} \rangle}{2 m_\mathrm{H}}. \end{aligned} \tag{11.7}$$

Since $\Omega r^2 \rho_\mathrm{wind} V_\mathrm{wind}^3 = L_\mathrm{wind}$ where Ω is the solid angle of the wind flow, this can be rearranged to give $\langle \rho_\mathrm{ISM} \rangle > \rho_\mathrm{wind,critical}$ where

$$\rho_\mathrm{wind,critical} = \frac{2 m_\mathrm{H} L_\mathrm{wind}}{3 \Omega r^2 V_\mathrm{wind} \mathrm{k_B} T_\mathrm{ISM}}. \tag{11.8}$$

This critical wind density is computed at the characteristic radius of the spheroid, r_spheroid, assuming $V_\mathrm{wind} = 10^4 \mathrm{km/s}$, $T_\mathrm{ISM} = 10^4 \mathrm{K}$ and $\Omega = \pi$, and the ISM density is approximated by

$$\langle \rho_\mathrm{ISM} \rangle = \frac{3 M_\mathrm{gas,spheroid}}{4\pi} r_\mathrm{spheroid}^3. \tag{11.9}$$

For numerical ease, the fraction, f_wind, of the wind luminosity added to the spheroid is adjusted smoothly through the $\rho_\mathrm{ISM} \approx \rho_\mathrm{wind,critical}$ region according to

$$f_\mathrm{wind} = \begin{cases} 0 & \text{if } x < 0, \\ 3x^2 - 2x^3 & \text{if } 0 \leq x \leq 1, \\ 1 & \text{if } x > 1, \end{cases} \tag{11.10}$$

where $x = \rho_\mathrm{ISM}/\rho_\mathrm{wind,critical} - 1/2$.

[1] Specifically, the jet power multiplied by $f_\mathrm{hot}[(M_\mathrm{hot}/M_\mathrm{total})(\Omega_\mathrm{M}/\Omega_\mathrm{b})]^2$ is added to the hot halo heating rate. The dependence on the gas fraction in the hot halo ensures that the heating rate goes smoothly to zero as the hot halo becomes depleted of gas.

The radial position, $r_\bullet$, evolves according to the selected radial migration method (see §16.4.1).

Interactions between black hole triplets are accounted for if `[tripleBlackHoleInteraction]=true` (and if at least three black holes exist within the node of course). In this case the triple is treated as consisting of an inner binary (assumed to be the central black hole and the black hole closest to it) and a third, singleton black hole. When the tertiary black hole reaches a separation of

$$a_\mathrm{h} = \frac{\mathrm{G}(M_{\bullet,1} + M_\mathrm{bullet,2})}{4\sigma^2} \tag{11.11}$$

it is assumed to undergo a triple interaction with the binary. Once a triple interaction occurs, no further triple interaction for the specific tertiary black hole can occur unless the host galaxy merges with another galaxy, at which point the black holes from the merging galaxy are eligible for another triple interaction in their new host.

The logic of what happens in a triple black hole interaction is taken from Volonteri et al. [2003]. Labelling the central black hole as 1, its binary partner as 2 and the tertiary black hole as 3, and defining

$$q_3 = \frac{M_{\bullet,3}}{M_{\bullet,1} + M_{\bullet,2}}, \tag{11.12}$$

then if $q_3 \leq 2$ then, if $M_{\bullet,3} \leq M_{\bullet,2}$ we set

$$a_3 = \frac{a_2}{1 + 0.4q_3}, \tag{11.13}$$

and define

$$E_\mathrm{bind} = \frac{\mathrm{G}M_{\bullet,3}M_{\bullet,1}}{a_3}, \tag{11.14}$$

and

$$\Delta K = 0.4q_3 E_\mathrm{bind}, \tag{11.15}$$

$i = 3$ and $j = 2$.

Otherwise if $q_3 \leq 2$ and $M_{\bullet,3} > M_{\bullet,2}$ we set

$$a_3 = \frac{a_3}{1 + 0.4q_3}, \tag{11.16}$$

and define

$$E_\mathrm{bind} = \frac{\mathrm{G}M_{\bullet,2}M_{\bullet,1}}{a_2}, \tag{11.17}$$

and

$$\Delta K = 0.4q_3 E_\mathrm{bind}, \tag{11.18}$$

$i = 2$ and $j = 3$.

Finally, if $q_3 > 2$, then we set

$$a_3 = 0.53a_3, \tag{11.19}$$

and define

$$E_\mathrm{bind} = \frac{\mathrm{G}M_{\bullet,2}M_{\bullet,1}}{a_2}, \tag{11.20}$$

and

$$\Delta K = 0.9q_3 E_\mathrm{bind}, \tag{11.21}$$

$i = 2$, $j = 3$.

Black hole i is identified as the "ejected" hole, with black hole j becoming the new binary member. Therefore

$$M_{\bullet,ejected} = M_{\bullet,i}. \tag{11.22}$$

and

$$M_{\rm binary} = M_{\bullet,\rm j} + M_{\bullet,1}. \tag{11.23}$$

The imparted velocities of these two systems are

$$V_{\rm ejected} = \left[\frac{2\Delta K}{(1 + M_{\bullet,ejected}/M_{\rm binary}) M_{\bullet,ejected}} \right]^{1/2} \tag{11.24}$$

and

$$V_{\rm binary} = \left[\frac{2\Delta K}{(1 + M_{\rm binary}/M_{\bullet,ejected}) M_{\rm binary}} \right]^{1/2}. \tag{11.25}$$

If

$$\frac{1}{2} V^2_{\rm ejected|binary} + \Phi(a_{\rm ejected|binary}) \geq 0 \tag{11.26}$$

for either velocity, then that system is ejected from the node. Ejected black holes are removed from the node. If the binary is ejected the central black hole is replaced with a "null", zero mass placeholder.

Event Evolution

Node mergers: None.

Satellite merging: The black holes in the two merging galaxies can be instantaneously merged, or taken at an initial separation (see §12.54), it is then evolved until reaching zero separation whereupon it is assumed to undergo merger. Properties are computed using the selected black hole binary merger method (see §16.4.1). In addition, the recoil velocity of the new black hole due to gravitational wave emission is computed using the selected method (see §12.56), and if greater than the potential at the center of the galaxy, is assumed to have escaped the galaxy. Black holes which escape the galaxy are simply discarded and no longer tracked. For computational purposes, they are replaced with a "null", zero mass black hole at the center of the galaxy. If any other black hole comes within a distance

$$a_{\rm h} = \frac{{\rm G}M_\bullet}{4\sigma^2}, \tag{11.27}$$

where σ is approximated to be the virial velocity of the dark matter halo, it is promoted to being the new "central" black hole of the node.

Node promotion: None.

Additional Output

If the `[blackHoleOutputAccretion]` input parameter is set to true, then rest mass accretion rate (in $M_\odot$ Gyr^{-1}), jet power (in $M_\odot$ km^2 s^{-1} Gyr^{-1}) and radiative efficiency of the black hole[2] are output as `blackHoleAccretionRate`, `blackHoleJetPower` and `blackHoleRadiativeEfficiency` respectively.

If the `[blackHoleOutputData]` input parameter is set to true, then the Masses (in $M_\odot$), Spins (for now just a scalar with no direction), final Radius (in Mpc), timescales (in Gyr) until merger, accretion rates (in $M_\odot perGyr$) and radiative Efficiencies of all the black holes in the galaxy are given as outputs in the `blackHole` section of the output hdf5. This also saves the tree node and merger tree index for further use when using the data.

The outputs of mergers are also automatically saved, as outputs in the `blackHoleMergers` section of the output hdf5. Those outputs are the time at which mergers happened and the mass ratio between the two merging black holes.

[2]Technically of the black hole plus accretion disk system.

11.1.2. "Simple" Implementation

Properties

The simple black hole implementation defines the following property:

`mass` The mass of the black hole: $M_\bullet$ `[blackHoleMass]`.

Initialization

Black holes are not initialized, they are created (with a seed mass given by `blackHoleSeedMass`) as needed.

Differential Evolution

In the simple black hole implementation the mass evolves as:

$$\dot{M}_\bullet = (1-\epsilon_{\rm wind})\epsilon_{\rm BH}\dot{M}_{\star,\rm spheroid} \tag{11.28}$$

$$\tag{11.29}$$

where $\epsilon_{\rm BH}$ is the ratio of rates at which the black hole and stellar spheroid grow. The black hole is assumed to cause feedback in two ways:

Radio-mode If `[blackHoleHeatsHotHalo]`=`true` and `[blackHoleAccretesFromHotHalo]`=`false` then a power $\epsilon_{\rm heat}\epsilon_{\rm BH}\dot{M}_{\star,\rm spheroid}{\rm c}^2$ where $\epsilon_{\rm heat}$ =`[blackHoleHeatingEfficiency]` is included in the hot halo heating rate providing that the halo is in the slow cooling regime (i.e. if the cooling radius is smaller than the virial radius; see, for example, Benson and Bower 2010) and the accretion rate onto the black hole is reduced by $\epsilon_{\rm heat}\epsilon_{\rm BH}\dot{M}_{\star,\rm spheroid}$. If `[blackHoleHeatsHotHalo]`=`true` and `[blackHoleAccretesFromHotHalo]`=`true` then a power $\epsilon_{\rm heat}\dot{M}_{\rm Eddington}{\rm c}^2$ is included in the hot halo heating rate providing that the halo is in the slow cooling regime and the accretion rate onto the black hole is increased[3] by $\dot{M}_{\rm Eddington}\epsilon_{\rm heat}(1-\epsilon_{\rm jet})/\epsilon_{\rm jet}$, where $\epsilon_{\rm jet}$ =`[blackHoleJetEfficiency]`;

Quasar-mode A mechanical wind luminosity of [Ostriker et al., 2010]

$$L_{\rm wind} = \epsilon_{\bullet,wind}\dot{M}_0{\rm c}^2, \tag{11.30}$$

where $\epsilon_{\bullet wind}$ =`[blackHoleWindEfficiency]` is the black hole wind efficiency, is added to the gas component of the spheroid (which, presumably, will respond with an outflow for example).

Event Evolution

Node mergers: None.

Satellite merging: The black holes in the two merging galaxies are instantaneously merged. Properties are computed using the selected black hole binary merger method (see §16.4.1).

Node promotion: None.

Additional Output

If the `[blackHoleOutputAccretion]` input parameter is set to true, then rest mass accretion rate (in $M_\odot$ Gyr^{-1}) is output as `blackHoleAccretionRate`.

[3] Note that mass is not removed from the hot halo to compensate, since the accretion rate is independent of the hot halo mass this could lead to negative mass in the halo.

11.2. Dynamics Statistics

This class collects statistics related to galaxy dynamics.

11.2.1. "Bars" Implementation

Properties

The "bars" dynamics statistics implementation defines the following properties:

`time` An array of times at which bar statistics are recorded.

`barInstabilityTimescale` The timescale of bar instability at each tabulated time.

`adiabaticRatio` The adiabatic ratio, a, of the galaxy at each tabulated time defined as:

$$a = \left(\frac{r_{\rm peri}}{v_{\rm peri}} \right) \left(\frac{2\pi r_{\rm disk}}{v_{\rm disk}} \right)^{-1}, \tag{11.31}$$

where $r_{\rm peri}$ is the pericentric distance of the galaxies orbit, $v_{\rm peri}$ is the orbital velocity at pericenter, $r_{\rm disk}$ is the characteristic radius of the disk, and $v_{\rm disk}$ is the circular velocity at that radius. For non-satellite galaxies the adiabatic ratio is set to -1.

Bar statistics are recorded at a frequency given by `[dynamicsStatisticsBarsFrequency]` times the host halo dynamical time.

Initialization

Component is not initialized, it is created as soon as a disk exists.

Differential Evolution

N/A.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

Additional Output

Bar statistics time series are output for each node to a group `Outputs/Output<O>/dynamicsStatistics/tree<T>` (where `<O>` is the output number and `<T>` is the tree index) into datasets named `time<N>`, `timeScale<N>`, and `adiabaticRatio<N>` (where `<N>` is the node index).

11.3. Hot Halo

11.3.1. "Very Simple" Implementation

Properties

The very simple hot halo implementation defines the following properties:

`mass` The mass of gas in the hot halo: $M_{\rm hot}$ `[hotHaloMass]`.

and the following pipes:

`hotHaloCoolingMass` The net cooling rate of gas mass is sent through this pipe. Any component may claim this pipe and connect to it, allowing it to receive the cooling gas.

`outflowingMass` Galactic components that wish to expel gas due to an outflow can send that mass through this pipe, where it will be received into the hot halo component.

Initialization

At initialization, nodes are assigned a mass of gas equal to their own mass, minus the mass of any progenitors, multiplied by $\Omega_{\rm b}/\Omega_{\rm Matter}$.

Differential Evolution

In the very simple hot halo implementation the hot gas mass and heavy element mass(es) evolves as:

$$\dot{M}_{\rm hot} = -\dot{M}_{\rm cooling} + \dot{M}_{\rm outflow}, \tag{11.32}$$

where $\dot{M}_{\rm cooling}$ is the rate of mass loss from the hot halo due to cooling (see §12.9.2. In the above $\dot{M}_{\rm outflow}$ is the net rate of outflow from any components in the node. For satellite galaxies, the outflow is instead directed to the hot halo of the host node.

Event Evolution

Node mergers: Any hot gas from the merging halo is transferred to its host halo.

Satellite merging: Any hot halo of the satellite node is added to that of the host node and the hot halo component removed from the satellite node.

Node promotion: Any hot halo of the parent node is added to that of the node prior to promotion.

Halo formation: None.

11.3.2. "Very Simple Delayed" Implementation

Properties

The delayed very simple hot halo implementation extends the "very simple" implementation by adding a reservoir for outflowed gas from which the hot halo is gradually replenished. It defines the following properties:

`outflowedMass` The mass of gas in the outflowed reservoir of the hot halo: $M_{\rm outflowed}$ `[hotHaloOutflowedMass]`.

Initialization

At initialization, nodes are assigned zero outflowed mass.

Differential Evolution

This implementation steals the `outflowingMass` pipe from the very simple component and redirects it to the outflowed mass reservoir. The resulting rates of change of hot and outflowed masses are then:

$$\begin{aligned} \dot{M}_\mathrm{hot} &= -\dot{M}_\mathrm{cooling} + \dot{M}_\mathrm{reincorporation}, \\ \dot{M}_\mathrm{outflowed} &= +\dot{M}_\mathrm{outflow} - \dot{M}_\mathrm{reincorporation}, \end{aligned} \tag{11.33}$$

where $\dot{M}_\mathrm{reincorporation}$ is the reincorporation rate of outflowed gas (see §12.26).

Event Evolution

Node mergers: Any outflowed gas from the merging halo is transferred to its host halo.

Satellite merging: Any outflowed halo of the satellite node is added to that of the host node and the outflowed mass component removed from the satellite node.

Node promotion: Any outflowed gas of the parent node is added to that of the node prior to promotion.

Halo formation: None.

11.3.3. "Standard" Implementation

Properties

The standard hot halo implementation defines the following properties:

`unaccretedMass` The mass of gas which could have accreted onto the halo if it always accreted baryons and dark matter in the universal proportion, but which failed to do so (e.g. perhaps due to being photoheated to a high temperature and so being resistant to accretion into shallow potential wells): M_failed.

`mass` The mass of gas in the hot halo: M_hot `[hotHaloMass]`.

`angularMomentum` The angular momentum of the gas in the hot halo, J_hot `[hotHaloAngularMomentum]`.

`abundances` The mass(es) of heavy elements in gas in the hot halo, $M_{Z,\mathrm{hot}}$ `[hotHalo{abundanceName}]`.

`outflowedMass` The mass of gas from outflows in the hot halo: $M_\mathrm{outflowed}$ `[hotHaloOutflowedMass]`.

`outflowedAngularMomentum` The angular momentum of the outflowed gas in the hot halo, $J_\mathrm{outflowed}$ `[hotHaloOutflowedAngularMomentum]`.

`outflowedAbundances` The mass(es) of heavy elements in outflowed gas, $M_{Z,\mathrm{outflowed}}$ `[hotHaloOutflowed{abundanceName}]`

`chemicals` The mass(es) of molceules in the hot gas, M_chemical `[hotHaloChemicals{chemicalName}]`.

`outerRadius` The outer boundary radius fo the hot halo: $r_\mathrm{hot,outer}$ `[hotHaloOuterRadius]`.

`strippedMass` The mass of gas which has been stripped from the hot halo (by ram pressure or tidal forces for example): $M_{\rm hot,stripped}$. This property is computed only if `[hotHaloTrackStrippedGas]=true`.

`strippedAbundances` The mass(es) of heavy elements in gas that has been stripped from the hot halo (by ram pressure or tidal forces for example), $M_{Z,\rm hot,stripped}$. These properties are computed only if `[hotHaloTrackStrippedGas]=true`.

and the following pipes:

`heatSource` Energy sent through this pipe is added to the hot halo and used to offset the cooling rate (see below; heat pushed should be in units if $M_\odot$ (km/s)^2 Gyr^{-1}).

`cooling[Mass|Angular_Momentum|Abundances]_To` The net cooling rate of gas mass (and metal content and magnitude of angular momentum) is sent through this pipe. Any component may claim this pipe and connect to it, allowing it to receive the cooling gas.

`outflowing[Mass|AngularMomentum|Abundances]_To` Galactic components that wish to expel gas due to an outflow can send that mass (plus metals and angular momentum) through this pipe, where it will be received into the hot halo component.

`massSink` Removes gas (and proportionate amounts of angular momentum and elements) from the hot gas halo.

Initialization

At initialization, any nodes with no children are assigned a hot halo mass, and failed accreted mass as dictated by the baryonic accretion method (see §12.2) and angular momentum based on the accreted mass and the halo spin parameter.

Differential Evolution

In the standard hot halo implementation the hot gas mass and heavy element mass(es) evolves as:

$$\dot{M}_{\rm failed} = \dot{M}_{\rm failed\ accretion} \tag{11.34}$$

$$\dot{M}_{\rm hot} = \dot{M}_{\rm accretion} - \dot{M}_{\rm cooling} + \dot{M}_{\rm outflow,return} - \dot{M}_{\rm expelled} - \dot{M}_{\rm hot,stripped}, \tag{11.35}$$

$$\dot{M}_{Z,\rm hot} = -\dot{M}_{\rm cooling}\frac{M_{Z,\rm hot}}{M_{\rm hot}} + \dot{M}_{Z,\rm outflow,return} - \dot{M}_{Z,\rm expelled} - \dot{M}_{Z,\rm hot,stripped}, \tag{11.36}$$

$$\dot{M}_{\rm chemical} = -[\dot{M}_{\rm cooling} + \dot{M}_{\rm expelled} + \dot{M}_{\rm hot,stripped}]\frac{M_{\rm chemical}}{M_{\rm hot}} + f_{\rm chemical,outflow}\dot{M}_{\rm outflow,return} + \dot{M}_{\rm chemical,reactions}, \tag{11.37}$$

$$\dot{r}_{\rm hot,outer} = \begin{cases} \frac{r_{\rm rp}-r_{\rm hot,outer}}{\tau_{\rm dynamical}} & \text{if } r_{\rm rp} < r_{\rm hot,outer} \\ 0 & \text{otherwise.} \end{cases} \tag{11.38}$$

$$\dot{M}_{\rm hot,stripped} = -4\pi\rho_{\rm hot}(r_{\rm hot,outer})r_{\rm hot,outer}^2\dot{r}_{\rm hot,outer} + \dot{M}_{\rm outflows}f_{\rm outflow,stripped} \tag{11.39}$$

$$\dot{M}_{Z,\rm hot,stripped} = -4\pi\rho_{\rm hot}(r_{\rm hot,outer})r_{\rm hot,outer}^2\dot{r}_{\rm hot,outer}(M_{Z,\rm hot}/M_{\rm hot}) + \dot{M}_{Z,\rm outflows}f_{\rm outflow,stripped} \tag{11.40}$$

where $r_{\rm rp}$ is the ram pressure stripping radius as computed by the `hotHaloRamPressureStrippingMethod` method (see §12.24), $\dot{M}_{\rm accretion}$ is the rate of growth of the hot component due to accretion from the IGM and $\dot{M}_{\rm failed\ accretion}$ is the rate of failed accretion from the IGM (these may include a component due to transfer of mass from the failed to accreted reservoirs) and $\dot{M}_{\rm cooling}$ is the rate of mass

loss from the hot halo due to cooling (see §12.9.2—cooling rates are computed using the current node if `[hotHaloCoolingFromNode]=current node` or from the formation node if that parameter is set to `formation node`) minus any heating rate defined as

$$\dot{M}_{\rm heating} = \dot{E}_{\rm input}/V^2_{\rm virial}, \tag{11.41}$$

where $\dot{E}_{\rm input}$ is the rate at which energy is being sent through the "energy input" pipe and $V_{\rm virial}$ is the virial velocity of the halo. The net cooling rate is never allowed to drop below zero. If the mass heating rate exceeds the mass cooling rate and `[hotHaloExcessHeatDrivesOutflow]=false` then the excess energy is not used and $\dot{M}_{\rm expelled}=0$. Alternatively, if `[hotHaloExcessHeatDrivesOutflow]=true` then

$$\dot{M}_{\rm expelled} = \begin{cases} \alpha_{\rm expel} M_{\rm hot}/\tau_{\rm dynamical} & \text{if } \dot{M}_{\rm heating} - \dot{M}_{\rm cool} > \alpha_{\rm expel} M_{\rm hot}/\tau_{\rm dynamical} \\ \dot{M}_{\rm heating} - \dot{M}_{\rm cool}, & \text{otherwise,} \end{cases} \tag{11.42}$$

where $\dot{M}_{\rm cool}$ is the intrinsic cooling rate in the halo (i.e. the cooling rate in the absence of any heating) and $\alpha_{\rm expel}=$`[hotHaloExpulsionRateMaximum]` limits the maximum rate at which mass can be expelled from the halo.

In the above, $f_{\rm chemical,return}$ if the mass fraction of each chemical species in the outflowed gas and is assumed to be equal to that given by the atomic ionization state functions (see §12.30) at the virial temperature and mean density of the halo. Finally, $\dot{M}_{\rm chemical,reactions}$ represents the rate of change of masses of chemical species due to chemical and atomic processes and is computed using the chemical rates functions (see §12.39). The angular momentum of the hot gas evolves as:

$$\dot{J}_{\rm hot} = \dot{M}_{\rm accretion}\frac{\dot{J}_{\rm node}}{\dot{M}_{\rm node}} - \dot{M}_{\rm cooling} r_{\rm cool} V_{\rm rotate} + \dot{J}_{\rm outflow,return} - \dot{M}_{\rm expelled}\frac{J_{\rm hot}}{M_{\rm hot}}, \tag{11.43}$$

where $\dot{M}_{\rm node}$ and $\dot{J}_{\rm node}$ are defined in §11.8. For the outflowed components:

$$\dot{M}_{\rm outflowed} = -\dot{M}_{\rm outflow,return} + \dot{M}_{\rm outflows}(1-f_{\rm outflow,stripped}), \tag{11.44}$$

$$\dot{M}_{Z,\rm outflowed} = -\dot{M}_{Z,\rm outflow,return} + \dot{M}_{Z,\rm outflows}(1-f_{\rm outflow,stripped}), \tag{11.45}$$

$$\tag{11.46}$$

and:

$$\dot{J}_{\rm outflowed} = -\dot{J}_{\rm outflow,return} + \dot{J}_{\rm outflows}. \tag{11.47}$$

In the above

$$\dot{M}|\dot{M}_Z|\dot{J}_{\rm outflow,return} = \alpha_{\rm outflow\ return\ rate}\frac{M|M_Z|J_{\rm outflowed}}{\tau_{\rm dynamical,halo}}, \tag{11.48}$$

where $\alpha_{\rm outflow\ return\ rate}=$ (`hotHaloOutflowReturnRate`) is an input parameter controlling the rate at which gas flows from the outflowed to hot reservoirs, and $\dot{M}|\dot{M}_Z|\dot{J}_{\rm outflows}$ are the net rates of outflow from any components in the node.

In the above, $f_{\rm outflow,stripped}$ is the fraction of outflowing material assumed to be stripped from the halo. The is computed following the algorithm of Font et al. [2008], namely

$$f_{\rm outflow,stripped} = \epsilon_{\rm strip}\frac{M_{\rm hot,outer}}{M_{\rm hot,virial}}, \tag{11.49}$$

where $\epsilon_{\rm strip}=$`[hotHaloOutflowStrippingEfficiency]` is an input parameter, $M_{\rm hot,outer}$ is the mass of hot gas contained within the outer radius of the hot halo and $M_{\rm hot,virial}$ is the mass of hot gas that would be present if the hot halo extended to the virial radius (i.e. if no stripping had occurred).

A fraction $1-$`[hotHaloAngularMomentumLossFraction]` of the cooling angular momentum rate, $\dot{M}_{\rm cooling} r_{\rm cool} V_{\rm rotate}$, is sent through the `Hot_Halo_Cooling_Angular_Momentum` pipe.

Event Evolution

Node mergers: If the `starveSatellites` parameter is true, then any hot halo properties of the minor node are added to those of the major node and the hot halo component removed from the minor node. Additionally in this case, any material outflowed or stripped from the the satellite galaxy to its hot halo is transferred to the hot halo of the host dark matter halo after each timestep. (Alternatively, if `starveSatellitesOutflowed=true` then only the outflowed and stripped gas is transferred to the host halo—the main hot gas reservoir is left in place.) If stripped mass is being tracked (i.e. if `[hotHaloTrackStrippedGas]=true`) then any stripped mass is transferred from the satellite galaxy to the hot halo of the host dark matter halo after each timestep. If `[hotHaloNodeMergerLimitBaryonFraction]=true` then the hot gas content of the merged node is limited such that the total baryon content of the node (including satellites) does not exceed the universal baryon fraction, if possible. Any gas removed to enforce this limit is placed into the unaccreted gas reservoir, from which is may eventually be reaccreted.

Satellite merging: If the `starveSatellites` parameter is false, then any hot halo properties of the satellite node are added to those of the host node and the hot halo component removed from the satellite node.

Node promotion: Any hot halo properties of the parent node are added to those of the node prior to promotion.

Halo formation: If `[hotHaloOutflowReturnOnFormation]=true` then all outflowed gas is returned to the hot gas reservoir on halo formation events (see §16.4.3).

11.3.4. "Outflow Tracking" Implementation

Properties

The outflow tracking hot halo implementation extends the "standard" implementation by adding the following properties:

`trackedOutflowMass` The mass of gas in the hot halo which arrived there directly via outflow: $M_{\rm outflow,track}$ `[hotHaloTrackedOutflowMass]`.

`trackedOutflowAbundances` The mass of elements in the hot halo which arrived there directly via outflow: $M_{Z,\rm outflow,track}$ `[hotHaloTrackedOutflowAbundances]`.

Initialization

Outflowed masses and element masses are initialized to zero.

Differential Evolution

The tracked outflow masses evolve according to:

$$\dot{M}|\dot{M}_{Z_{\rm outflow,track}} = \alpha_{\rm outflow\ return\ rate}\frac{M|M_{Z_{\rm outflowed}}}{\tau_{\rm dynamical,halo}} - M|M_{Z_{\rm outflow,track}}\dot{M}_{\rm expelled}/M \quad (11.50)$$

(11.51)

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

Halo formation: None.

11.4. Galactic Disk

11.4.1. "Very Simple" Implementation

This implementation assumes a disk with no structural properties—it consists of just gas and stellar masses.

Properties

The very simple galactic disk implementation defines the following properties:

`massGas` The mass of gas in the disk: $M_{\rm disk,gas}$ [`diskMassGas`];

`massStellar` The mass of stars in the disk: $M_{\rm disk,stars}$ [`diskMassStellar`].

Initialization

No initialization is performed—disks are created as needed.

Differential Evolution

In the very simple galactic disk implementation the gas mass evolves as:

$$\dot{M}_{\rm disk,gas} = \dot{M}_{\rm cooling} - \dot{M}_{\rm outflow,disk} - \dot{M}_{\rm stars,disk}, \tag{11.52}$$

where the rate of change of stellar mass is

$$\dot{M}_{\rm stars,disk} = \Psi - \dot{R}, \tag{11.53}$$

where $\dot{R}$ is the rate of mass recycling from stars, and

$$\Psi = \frac{M_{\rm disk,gas}}{\tau_{\rm disk,star\ formation}} \tag{11.54}$$

with $\tau_{\rm disk,star\ formation}$ being the greater of the star formation timescale and $\Gamma_{\rm disk,starformation,minimum}\tau_{\rm dyn}$, where $\tau_{\rm dyn}$ is the dynamical time of the halo, and $\Gamma_{\rm disk,starformation,minimum}$ = `[diskStarFormationTimescaleMinimum]`. The outflow rate, $\dot{M}_{\rm outflow,disk}$, is computed for the current star formation rate and gas properties by the prescriptions for non-expulsive supernova feedback (see §12.52), but is limited to a maximum of $M_{\rm disk,gas}/\Gamma_{\rm disk,outflow,minimum}\tau_{\rm dyn}$, where $\Gamma_{\rm disk,outflow,minimum}$ = `[diskOutflowTimescaleMinimum]`. This outflow is piped to the hot halo component.

Event Evolution

Node mergers: None

Satellite merging: Disks may be destroyed (or, potentially, created or otherwise modified) as the result of a satellite merging event, as dictated by the selected merger remnant mass movement method (see §12.18.1).

Node promotion: None

11.4.2. "Very Simple Size" Implementation

This implementation extends the `verySimple` disk class by adding a half-mass radius property. No other assumptions about the mass distribution are made.

Properties

The very simple size galactic disk implementation defines the following additional properties:

`radius` The half-mass radius of the disk: $r_{\mathrm{disk},1/2}$ [`diskRadius`].

Initialization

No initialization is performed—disks are created as needed.

Differential Evolution

N/A—disk radii are computed using the selected galactic structure solver.

Event Evolution

Node mergers: None

Satellite merging: None

Node promotion: None

11.4.3. "Standard Implementation

This implementation assumes a disk with a cylindrical symmetry and a flattened profile in which stars trace gas. Currently, one option for the density profile is allowed[4]:

`exponentialDisk` Assumes an exponential profile, $\rho(R,z) = \rho_0 \exp(-r/r_{\mathrm{s}})\mathrm{sech}^2(z/z_{\mathrm{s}})$, for the disk component of a galaxy. The thickness, $z_{\mathrm{s}}/r_{\mathrm{s}}$ is set by the parameter [`heightToRadialScaleDisk`].

[4]The disk density distribution is handled internally using a `massDistribution` object (see §16.4.1). As such, any mass distribution implemented as an extension of the `massDistribution` class (and which is described by a single length scale) could be trivially addded to the standard disk component.

Properties

The standard galactic disk implementation defines the following properties:

`massGas` The mass of gas in the disk: $M_{\rm disk,gas}$ [`diskMassGas`].

`abundancesGas` The mass of elements in the gaseous disk: $M_{Z,\rm disk,gas}$ [`diskAbundancesGas{abundanceName}`].

`massStellar` The mass of stars in the disk: $M_{\rm disk,stars}$ [`diskMassStellar`].

`abundancesStellar` The mass of elements in the stellar disk: $M_{Z,\rm disk,stars}$ [`diskAbundancesStellar{abundanceName}`].

`luminositiesStellar` The luminosities (in multiple bands) of the stellar disk: $L_{\rm disk,stars}$ [`diskLuminositiesStellar{lumino`

`angularMomentum` The angular momentum of the disk, $J_{\rm disk}$ [`diskAngularMomentum`].

`radius` The radial scale length of the disk, $R_{\rm disk}$ [`diskRadius`].

`velocity` The circular velocity of the disk at $R_{\rm disk}$, $V_{\rm disk}$ [`diskVelocity`].

`massStellarFormed` The total mass of stars ever formed in the disk: $M_{\rm disk,stars,formed}$.

`fractionMassRetained` The fraction of mass retained in the disk as a result of transfer processes in which the transfer is proportional to the current mass: $f_{\rm retained}$.

Initialization

No initialization is performed—disks are created as needed.

Differential Evolution

In the standard galactic disk implementation the gas mass evolves as:

$$\dot{M}_{\rm disk,gas} = \dot{M}_{\rm cooling} - \dot{M}_{\rm outflow,disk} - \dot{M}_{\rm stars,disk} - \frac{M_{\rm disk,gas}}{\tau_{\rm bar}} - \dot{M}_{\rm rampressure} - \frac{M_{\rm disk,gas}}{M_{\rm disk,gas}+M_{\rm disk,stars}}\dot{M}_{\rm tidal}, \tag{11.55}$$

where the rate of change of stellar mass is

$$\dot{M}_{\rm stars,disk} = \Psi - \dot{R} - \frac{M_{\rm stars,disk}}{\tau_{\rm bar}} - \frac{M_{\rm disk,stars}}{M_{\rm disk,gas}+M_{\rm disk,stars}}\dot{M}_{\rm tidal}, \tag{11.56}$$

$$\dot{M}_{\rm stars,disk,formed} = \Psi, \tag{11.57}$$

with

$$\Psi = \frac{M_{\rm disk,gas}}{\tau_{\rm disk,star\ formation}} \tag{11.58}$$

with $\tau_{\rm disk,star\ formation}$ being the star formation timescale and $\dot{R}$ is the rate of mass recycling from stars and $\tau_{\rm bar}$ is a bar instability timescale (see §12.12). If `[diskStarFormationInSatellites]=true` then the star formation rate is forced to zero in satellite galaxies. The mass removed from the disk by the bar instability mechanism is added to the active spheroid component. Element abundances (including total metals) evolve according to:

$$\dot{M}_{Z,\rm disk,gas} = \dot{M}_{Z\rm cooling} - \dot{M}_{Z,\rm outflow,disk} - \dot{M}_{Z,\rm stars,disk} + \dot{y} - \frac{M_{Z,\rm disk,gas}}{M_{\rm disk,gas}}\dot{M}_{\rm rampressure} - \frac{M_{Z,\rm disk,gas}}{M_{\rm disk,gas}+M_{\rm disk,stars}}\dot{M}_{\rm tidal}, \tag{11.59}$$

and

$$\dot{M}_{Z,\mathrm{stars,disk}} = \Psi \frac{M_{Z,\mathrm{disk,gas}}}{M_{\mathrm{disk,gas}}} - \dot{R}_Z - \frac{M_{Z,\mathrm{disk,stars}}}{M_{\mathrm{disk,gas}} + M_{\mathrm{disk,stars}}} \dot{M}_{\mathrm{tidal}} \tag{11.60}$$

where $\dot{y}$ is the rate of element yield from stars and $\dot{R}_Z$ is the rate of element recycling. The angular momentum evolves as:

$$\dot{J}_{\mathrm{disk}} = \dot{J}_{\mathrm{cooling}} - \left[\dot{M}_{\mathrm{outflow,disk}} + \frac{M_{\mathrm{disk,gas}} + M_{\mathrm{disk,stars}}}{\tau_{\mathrm{bar}}} + \dot{M}_{\mathrm{rampressure}} + \dot{M}_{\mathrm{tidal}} \right] \frac{J_{\mathrm{disk}}}{M_{\mathrm{disk,gas}}}. \tag{11.61}$$

The outflow rate, $\dot{M}_{\mathrm{outflow,disk}}$, is computed for the current star formation rate and gas properties by the stellar properties subsystem (see §12.47) and prescriptions for expulsive and non-expulsive supernova feedback (see §12.53 and §12.52 respectively), but is not allowed to exceed $M_{\mathrm{gas,disk}}/\alpha_{\mathrm{outflowminimum,disk}}\tau_{\mathrm{disk,dynamical}}$, where $\tau_{\mathrm{disk,dynamical}} = R_{\mathrm{disk}}/V_{\mathrm{disk}}$ is the dynamical time of the disk and $\alpha_{\mathrm{outflowminimum,disk}} =$`[diskOutflowTimescaleMinimum` is the shortest timescale (in units of the dynamical timescale) on which gas can be removed from the disk. This limit prevents the disk being depleted on arbitrarily short timescales. The non-expulsive component of the outflow is piped to the hot halo component. The ram pressure and tidal mass loss rates, $\dot{M}_{\mathrm{rampressure}}$ and $\dot{M}_{\mathrm{tidal}}$, are computed using the selected methods (see §12.40 and §12.58 respectively). Finally, stellar luminosities evolve according to:

$$\dot{L}_{\mathrm{disk,stars}} = \Psi \mathcal{L}_\lambda(t_0 - t, Z_{\mathrm{gas}}) - \frac{L_{\mathrm{disk,stars}}}{\tau_{\mathrm{bar}}} - \frac{L_{\mathrm{disk,stars}}}{M_{\mathrm{disk,gas}} + M_{\mathrm{disk,stars}}} \dot{M}_{\mathrm{tidal}}, \tag{11.62}$$

where $\mathcal{L}_\lambda(t, Z)$ is the luminosity-to-mass ratio in the relevant band for a stellar population of age t and metallicity Z. The fraction of mass retained in the disk, f_{retained}, is given by:

$$\dot{f}_{\mathrm{retained}} = -\frac{f_{\mathrm{retained}}}{\tau_{\mathrm{bar}}}, \tag{11.63}$$

where the initial value of f_{retained} is arbitrary as we will be interested only in ratios of the quantity.

Integral Evolution

The standard disk component supports solving for the stellar luminosities as inactive variables, if the parameter `[diskLuminositiesStellarInactive]=true`. Across a timestep t_i to t_{i+1} the change in luminosity can be written as the following integral:

$$\Delta L_{\mathrm{disk,stars}} = \int_{t_i}^{t_{i+1}} \mathrm{d}t \Psi \mathcal{L}_\lambda(t_0 - t, Z_{\mathrm{gas}}) \frac{f_{\mathrm{retained}}(t_{i+1})}{f_{\mathrm{retained}}(t)} + L_{\mathrm{disk,stars}}(t_i) \frac{\dot{f}_{\mathrm{retained}}(t)}{f_{\mathrm{retained}}(t_i)}, \tag{11.64}$$

$$\Delta L_{\mathrm{spheroid,stars}} = \int_{t_i}^{t_{i+1}} \mathrm{d}t \Psi \mathcal{L}_\lambda(t_0 - t, Z_{\mathrm{gas}}) \left(1 - \frac{f_{\mathrm{retained}}(t_{i+1})}{f_{\mathrm{retained}}(t)} \right) - L_{\mathrm{disk,stars}}(t_i) \frac{\dot{f}_{\mathrm{retained}}(t)}{f_{\mathrm{retained}}(t_i)} \tag{11.65}$$

$$\tag{11.66}$$

The first term in the integral for disk stellar luminosity is just the usual production of starlight due to star formation, reduced by a factor $f_{\mathrm{retained}}(t_{i+1})/f_{\mathrm{retained}}(t)$ to account for that which will be retained in the disk at the end of the timestep. The second term accounts for transfer of starlight produced at $t < t_i$, since it integrates to $L_{\mathrm{disk,stars}}(t_i)(f_{\mathrm{retained}}(t_{i+1})/f_{\mathrm{retained}}(t_i) - 1)$ which is the change in the starlight of the disk over the timestep. The functions $f_{\mathrm{retained}}(t)$ and $M_{\mathrm{stars,disk,formed}}(t)$ have already been solved for during the differential evolution phase. Therefore, $f_{\mathrm{retained}}(t)$ and $\dot{f}_{\mathrm{retained}}(t)$ are available for this calculation. Furthermore, we can make the replacement $\Psi = \dot{M}_{\mathrm{stars,disk,formed}}(t)$ in the above, allowing us to avoid recomputing Ψ directly in these integral. The integral for the spheroid component simply reflects that starlight not retained in the disk is transferred to the spheroid.

Event Evolution

Node mergers: None

Satellite merging: Disks may be destroyed (or, potentially, created or otherwise modified) as the result of a satellite merging event, as dictated by the selected merger remnant mass movement method (see §12.18.1).

Node promotion: None

Additional Output

If the `[diskOutputStarFormationRate]` input parameter is set to true, then the instantaneous star formation rate in the disk (in units of $M_\odot$ Gyr^{-1}) will be included in the output, as `diskStarFormationRate`.

Structure

The radial size of the disk is found solving for equilibrium (i.e. the radius is such that the angular momentum of material at that radius is sufficient to provide rotational support) at the specified `[diskStructureSolverRadius]` which is given in units of the disk scale length. In converting from the mean specific angular momentum of the disk to the angular momentum at that radius, a flat rotation curve is assumed, i.e.:

$$j(r)/\langle j \rangle = rV \Bigg/ \frac{\int_0^\infty 2\pi r' \Sigma(r') r' V \mathrm{d}r'}{\int_0^\infty 2\pi r' \Sigma(r') \mathrm{d}r'} \,. \tag{11.67}$$

The option `[diskRadiusSolverCole2000Method]`, if set to `true`, alters this behavior to match that of the structure solver used by Cole et al. [2000], in which adiabatic contraction of the dark matter halo is solved for assuming that the disk has a spherical mass dsitribution. The specific angular momentum passed to the structure solver will be modified as follows in this case:

$$j(r) \rightarrow \left[j^2(r) - \left(V^2_\mathrm{disk}(r) r^2 - \mathrm{G} M_\mathrm{disk}(<r) r \right) \right]^{1/2} , \tag{11.68}$$

where V_disk is the rotation curve in the plane of the disk. This adjustment accounts for the difference between a thin disk and spherical mass distribution. Note that in this case (as in Cole et al. 2000) the resulting disk will not precisely satisfy $j(r) = rV_\mathrm{c}(r)$ where $V_\mathrm{c}(r)$ is the net rotation curve.

11.5. Galactic Spheroid

11.5.1. "Very Simple" Implementation

This implementation assumes a spheroid consisting of just gas and stellar masses, plus a half-mass radius (with no other assumption about structure being made).

Properties

The very simple galactic spheroid implementation defines the following properties:

`massGas` The mass of gas in the spheroid: $M_\mathrm{spheroid,gas}$ [`spheroidMassGas`];

`massStellar` The mass of stars in the spheroid: $M_\mathrm{spheroid,stars}$ [`spheroidMassStellar`].;

`radius` The half-mass radius of the sphreoid: $r_\mathrm{spheroid,1/2}$ [`spheroidRadius`].

Initialization

No initialization is performed—spheroids are created as needed.

Differential Evolution

Spheroid radii are computed using the selected galactic structure solver. In the very simple galactic spheroid implementation the gas mass evolves as:

$$\dot{M}_{\rm spheroid,gas} = \dot{M}_{\rm cooling} - \dot{M}_{\rm outflow,spheroid} - \dot{M}_{\rm stars,spheroid}, \tag{11.69}$$

where the rate of change of stellar mass is

$$\dot{M}_{\rm stars,spheroid} = \Psi - \dot{R}, \tag{11.70}$$

where $\dot{R}$ is the rate of mass recycling from stars, and

$$\Psi = \frac{M_{\rm spheroid,gas}}{\tau_{\rm spheroid,star\ formation}} \tag{11.71}$$

with $\tau_{\rm spheroid,star\ formation}$ being the greater of the star formation timescale and $\Gamma_{\rm spheroid,starformation,minimum}\tau_{\rm dyn}$, where $\tau_{\rm dyn}$ is the dynamical time of the halo, and $\Gamma_{\rm spheroid,starformation,minimum}$ =`[spheroidStarFormationTimescaleMinimum]`. The outflow rate, $\dot{M}_{\rm outflow,spheroid}$, is computed for the current star formation rate and gas properties by the prescriptions for non-expulsive supernova feedback (see §12.52), but is limited to a maximum of $M_{\rm spheroid,gas}/\Gamma_{\rm spheroid,outflow,minimum}\tau_{\rm dyn}$, where $\Gamma_{\rm spheroid,outflow,minimum}$ =`[spheroidOutflowTimescaleMinimum]`. This outflow is piped to the hot halo component.

Event Evolution

Node mergers: None

Satellite merging: Spheroids may be destroyed (or, potentially, created or otherwise modified) as the result of a satellite merging event, as dictated by the selected merger remnant mass movement method (see §12.18.1).

Node promotion: None

11.5.2. "Standard" Implementation

The standard spheroid implementation assumes a spheroid density profile described by a single length scale in which stars trace gas. Currently, two options for the density profile are allowed[5]:

`hernquist` Assumes a Hernquist profile [Hernquist, 1990] for the spheroidal component of a galaxy.

`sersic` Assumes a Sérsic profile (Sérsic 1963; see also Mazure and Capelato 2002) for the spheroidal component of a galaxy in which stars trace gas. The projected density profile of the spheroid is given by:

$$\Sigma(R) \propto \exp\left(-b_{\rm n} R^{1/n}\right), \tag{11.72}$$

where the Sérsic index, n =`[spheroidSersicIndex]` and the coefficient $b_{\rm n} = 2.303(0.8689n - 0.1447)$ Wadadekar et al. [1999]. The 3D density distribution for a given n is inferred by solving the relevant inverse Abel integral.

[5] The spheroid density distribution is handled internally using a `massDistribution` object (see §16.4.1). As such, any mass distribution implemented as an extension of the `massDistribution` class (and which is described by a single length scale) could be trivially addded to the standard spheroid component.

Properties

The standard galactic spheroid implementation defines the following properties:

`masGass` The mass of gas in the spheroid: $M_{\rm spheroid,gas}$ [`spheroidMassGas`].

`abundancesGas` The mass of elements in the gaseous spheroid: $M_{Z,\rm spheroid,gas}$ [`spheroidAbundancesGas{abundanceName}`].

`massStellar` The mass of stars in the spheroid: $M_{\rm spheroid,stars}$ [`spheroidMassStellar`].

`abundancesStellar` The mass of elements in the stellar spheroid: $M_{Z,\rm spheroid,stars}$ [`spheroidAbundancesStellar{abundancel`

`luminositiesStellar` The luminosities (in multiple bands) of the stellar spheroid: $L_{\rm spheroid,stars}$ [`spheroidLuminositiesSte`

`angularMomentum` The pseudo-angular momentum[6] of the spheroid, $J_{\rm spheroid}$ [`spheroidAngularMomentum`]. The parameter [`spheroidAngularMomentumAtScaleRadius`] controls the ratio of the specific pseudo-angular momentum at the scale radius of the standard spheroid to the mean specific pseudo-angular momentum. By default, this parameter is set to [`spheroidAngularMomentumAtScaleRadius`] $= I_2/I_3$, where

$$I_n = \int_0^\infty \rho(r) r^n {\rm d}r, \tag{11.73}$$

and $\rho(r)$ is the spheroid density profile, which is appropriate for a flat rotation curve. In some cases (e.g. the Hernquist profile) one or both of I_2 and I_3 can be infinite. In such cases [`spheroidAngularMomentumAtScaleRa`] $= 0.5$ is assumed by default. If a finite truncation radius is assumed, or a different rotation curve is assumed, this ratio may be finite. The [`spheroidAngularMomentumAtScaleRadius`] parameter allows control over these assumptions.

`radius` The radial scale length of the spheroid, $r_{\rm spheroid}$ [`spheroidRadius`].

`velocity` The circular velocity of the spheroid at $r_{\rm spheroid}$, $V_{\rm spheroid}$ [`spheroidVelocity`].

`massStellarFormed` The total mass of stars ever formed in the spheroid: $M_{\rm spheroid,stars,formed}$.

and the following pipes:

`energyInput` Energy sent through this pipe is added to the gas of the spheroid and will result in an outflow (see below). Input energy should be in units of $M_\odot$ km^2 s^{-2} Gyr^{-1} and must be positive (energy cannot be removed from the gas via this pipe).

`massGasSink` Removes gas (and proportionate amounts of angular momentum and elements) from the spheroid gas. Removed mass should be in units of $M_\odot$ and must be positive (a negative mass sink would add mass to the spheroid which is not allowed via this pipe).

Initialization

No initialization is performed—spheroids are created as needed.

[6] Effectively the angular momentum that the spheroid would have, were it rotationally supported rather than pressure supported.

Differential Evolution

In the standard galactic spheroid implementation the gas mass evolves as[7]:

$$\dot{M}_{\rm spheroid,gas} = -\dot{M}_{\rm outflow,spheroid} - \dot{M}_{\rm stars,spheroid} - \dot{M}_{\rm rampressure} - \frac{M_{\rm spheroid,gas}}{M_{\rm spheroid,gas}+M_{\rm spheroid,stars}}\dot{M}_{\rm tidal}, \tag{11.74}$$

where the rate of change of stellar mass is

$$\dot{M}_{\rm stars,spheroid} = \Psi - \dot{R} - \frac{M_{\rm spheroid,stars}}{M_{\rm spheroid,gas}+M_{\rm spheroid,stars}}\dot{M}_{\rm tidal}, \tag{11.75}$$

$$\dot{M}_{\rm stars,disk,formed} = \Psi, \tag{11.76}$$

with

$$\Psi = \frac{M_{\rm spheroid,gas}}{\tau_{\rm spheroid,star\ formation}} \tag{11.77}$$

with $\tau_{\rm spheroid,star\ formation}$ being the star formation timescale and $\dot{R}$ is the rate of mass recycling from stars. If `[spheroidStarFormationInSatellites]=true` then the star formation rate is forced to zero in satellite galaxies. Element abundances (including total metals) evolve according to:

$$\dot{M}_{Z,\rm spheroid,gas} = -\dot{M}_{Z,\rm outflow,spheroid} - \dot{M}_{Z,\rm stars,spheroid} + \dot{y} - \frac{M_{Z,\rm spheroid,gas}}{M_{\rm spheroid,gas}}\dot{M}_{\rm rampressure} - \frac{M_{Z,\rm spheroid,gas}}{M_{\rm spheroid,gas}+M_{\rm spheroid,stars}}\dot{M}_{\rm tidal}, \tag{11.78}$$

and

$$\dot{M}_{Z,\rm stars,spheroid} = \Psi\frac{M_{Z,\rm spheroid,gas}}{M_{\rm spheroid,gas}} - \dot{R}_Z - \frac{M_{Z,\rm spheroid,stars}}{M_{\rm spheroid,gas}+M_{\rm spheroid,stars}}\dot{M}_{\rm tidal} \tag{11.79}$$

where $\dot{y}$ is the rate of element yield from stars and $\dot{R}_Z$ is the rate of element recycling. The angular momentum evolves as:

$$\dot{J}_{\rm spheroid} = -(\dot{M}_{\rm outflow,spheroid}+\dot{M}_{\rm rampressure}+\dot{M}_{\rm tidal})\frac{J_{\rm spheroid}}{M_{\rm spheroid,gas}+M_{\rm spheroid,stars}} + |\mathcal{T}|(M_{\rm spheroid,gas}+M_{\rm spheroid,stars})R^2_{\rm spheroid}. \tag{11.80}$$

The outflow rate, $\dot{M}_{\rm outflow,spheroid}$, is computed for the current star formation rate and gas properties by the stellar properties subsystem (see §12.47) and prescriptions for expulsive and non-expulsive supernova feedback (see §12.53 and §12.52 respectively), with an additional contribution given by

$$\dot{M}_{\rm outflow,spheroid} = \beta_{\rm spheroid,energy}\frac{\dot{E}_{\rm gas,spheroid}}{V^2_{\rm spheroid}} \tag{11.81}$$

where $\beta_{\rm spheroid,energy}$ =`[spheroidEnergeticOutflowMassRate]` is an input parameter, and $\dot{E}_{\rm gas,spheroid}$ is any input energy sent through the `Tree_Node_Spheroid_Gas_Energy_Input` pipe, but is not allowed to exceed $M_{\rm gas,spheroid}/\alpha_{\rm outflowminimum,spheroid}\tau_{\rm spheroid,dynamical}$, where $\tau_{\rm spheroid,dynamical} = R_{\rm spheroid}/V_{\rm spheroid}$ is the dynamical time of the spheroid and $\alpha_{\rm outflowminimum,spheroid}$ =`[spheroidOutflowTimescaleMinimum]` is the shortest timescale (in units of the dynamical timescale) on which gas can be removed from the

[7]There may be an additional contribution to the mass and angular momentum rates of change in the spheroid due to material transferred from the disk component via the bar instability mechanism (see §11.4.3). This is not included here as it is not intrinsic to this specific spheroid implementation—it is handled explicitly by the disk component and so applies equally to any spheroid component implementation.

spheroid. This limit prevents the spheroid being depleted on arbitrarily short timescales. The non-expulsive component of the outflow is piped to the hot halo component. The ram pressure and tidal mass loss rates, $\dot{M}_{\rm rampressure}$ and $\dot{M}_{\rm tidal}$, are computed using the selected methods (see §12.40 and §12.58 respectively). The final term in 11.80 accounts for tidal heating of the spheroid due to the tidal field, $\mathcal{T}$.

Finally, stellar luminosities evolve according to:

$$\dot{L}_{\rm spheroid,stars} = \Psi \mathcal{L}_\lambda(t_0 - t, Z_{\rm gas}) - \frac{L_{\rm spheroid,stars}}{M_{\rm spheroid,gas} + M_{\rm spheroid,stars}} \dot{M}_{\rm tidal}, \tag{11.82}$$

where $\mathcal{L}_\lambda(t, Z)$ is the luminosity-to-mass ratio in the relevant band for a stellar population of age t and metallicity Z.

Integral Evolution

The standard spheroid component supports solving for the stellar luminosities as inactive variables, if the parameter `[spheroidLuminositiesStellarInactive]=true`. Across a timestep t_i to t_{i+1} the change in luminosity can be written as the following integral:

$$\Delta L_{\rm spheroid,stars} = \int_{t_i}^{t_{i+1}} {\rm d}t \Psi \mathcal{L}_\lambda(t_0 - t, Z_{\rm gas}), \tag{11.83}$$

which is just the usual production of starlight due to star formation. As the function $M_{\rm stars,spheroid,formed}(t)$ has already been solved for during the differential evolution phase we can make the replacement $\Psi = \dot{M}_{\rm stars,disk,formed}(t)$ in the above, allowing us to avoid recomputing Ψ directly in these integral.

Event Evolution

Node mergers: None

Satellite merging: Spheroids may be created as the result of a satellite merging event, as dictated by the selected merger remnant mass movement method (see §16.4.1).

Node promotion: None.

Additional Output

If the `[spheroidOutputStarFormationRate]` input parameter is set to true, then the instantaneous star formation rate in the spheroid (in units of $M_\odot$ Gyr^{-1}) will be included in the output, as `spheroidStarFormationRate`.

11.6. Host History

This component class tracks various properties of the host halo of each node over time.

11.6.1. "Standard" Implemenation

Properties

The standard host history implementation defines the following properties:

`hostMassMaximum` The maximum mass of the host halo in which this node has ever been hosted: $M_{\rm host,maximum}$ [`hostHistoryHostMassMaximum`].

Initialization

The maximum host mass is initialized to the initial host mass, or to -1 for initially isolated nodes.

Differential Evolution

N/A.

Event Evolution

Post evolution: Immediately after evolution of the node, the maximum host mass is set to the maximum of the current host mass and the previous maximum host mass.

Node mergers: As for "post evolution".

Satellite merging: None.

Node promotion: As for "post evolution".

11.7. Mass Flow Statistics

This component class tracks the flow of mass between different components of a node.

11.7.1. "Standard" Implemenation

Properties

The standard mass flow statistics implementation defines the following properties:

`cooledMass` The cumulative mass of has which has cooled directly onto this galaxy: $M_{\rm cooled}$ [`massFlowStatisticsCooledMass`

Initialization

The cooled mass is initialized to zero.

Differential Evolution

The cooled mass increases at a rate equal to the cooling rate onto the galaxy:

$$\dot{M}_{\rm cooled} = \dot{M}_{\rm cool}. \tag{11.84}$$

Event Evolution

Post evolution: None.

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.8. Basic Properties

Basic properties are the total mass of a node and the cosmic time at which it currently exists.

11.8.1. "Non-evolving" Implemenation

Properties

The non-evolving basic properties implementation defines the following properties:

`mass` The total mass of the node: $M_{\rm node}$ [`basicMass`].

`time` The time at which the node is defined: $t_{\rm node}$.

`timeLastIsolated` The time at which the node was last an isolated halo (i.e. not a subhalo): [`basicTimeLastIsolated`].

Initialization

All basic properties are required to be initialized by the merger tree construction routine.

Differential Evolution

Properties are evolved according to:

$$\dot{M}_{\rm node} = 0 \tag{11.85}$$
$$\dot{t}_{\rm node} = 1. \tag{11.86}$$

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: $M_{\rm node}$ is updated to the node mass of the parent prior to promotion.

11.8.2. "Standard Implemenation

Properties

The standard basic properties implementation defines the following properties:

`mass` The total mass of the node: $M_{\rm node}$ [`basicMass`].

`time` The time at which the node is defined: $t_{\rm node}$.

`timeLastIsolated` The time at which the node was last an isolated halo (i.e. not a subhalo): [`basicTimeLastIsolated`].

Initialization

All basic properties are required to be initialized by the merger tree construction routine.

Differential Evolution

Properties are evolved according to:

$$\dot{M}_{\rm node} = \begin{cases} \frac{M_{\rm node,parent}-M_{\rm node}}{t_{\rm node,parent}-t_{\rm node}} & \text{if primary progenitor} \\ 0 & \text{otherwise,} \end{cases} \tag{11.87}$$

$$\dot{t}_{\rm node} = 1, \tag{11.88}$$

where the "parent" subscript indicates a property of the parent node in the merger tree.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: $M_{\rm node}$ is updated to the node mass of the parent prior to promotion.

11.8.3. "Standard-Tracking Implemenation

Properties

The standard-tracking basic properties implementation extends the standard implementation and defines the following additional properties:

`massMaximum` The maximum total mass of the node achieved prior to the current time along this node's branch: $M_{\rm node,maximum}$ [`basicMassMaximum`].

Initialization

The maximum mass along each branch is computed from the merger tree structure at initialization time.

Differential Evolution

None.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: $M_{\rm node,maximum}$ is updated to the node maximum mass of the parent prior to promotion.

11.8.4. "Standard-Extended Implemenation

Properties

The standard-extended basic properties implementation extends the standard implementation and defines the following additional properties:

`massBertschinger` The "Bertschinger" mass of the node, defined as the mass enclosing a density contrast equal to that for the spherical collapse model: $M_{\rm node,Bertschinger}$ [`basicMassBertschinger`].

`accretionRateBertschinger` The accretion rate of "Bertschinger" mass onto the node: $\dot{M}_{\rm node,Bertschinger}$ [`basicAccretionRateBertschinger`].

`radiusTurnaround` The turnaround radius corresponding to the current "Bertshcinger"mass: $R_{\rm ta}$ [`basicRadiusTurnaround`]

Initialization

The Bertschinger mass and accretion rate for each node are computed from $M_{\rm basic}$ and the dark matter density profile. The turnaround radius is computed from the virial radius (under the appropriate definition for the Bertschinger mass) and the ratio of turnaround to virial radius from spherical collapse models. The specific spherical collapse model to use is determined by the `[nodeComponentBasicExtendedSphericalCollapseType]` parameter—a value of "`matterLambda`" causes the solution for matter+cosmological constant universes to be used, while a value of "`matterDarkEnergy`" causes the solution for matter+dark energy universes to be used.

Differential Evolution

None.

Event Evolution

Node mergers: The accretion rate of Bertschinger mass is set to zero.

Satellite merging: None.

Node promotion: $\dot{M}_{\rm node,Bertschinger}$ is updated to the node Bertschinger accretion rate of the parent prior to promotion.

11.9. Position

The position component implements the position and velocity of each galaxy. See §10.3 for important notes on velocity definitions in Galacticus.

11.9.1. "Preset" Implemenation

Properties

The preset position implementation defines the following properties:

`position` The 3-D position of the node: $\mathbf{x}$ [`positionPosition[X|Y|Z]`].

`velocity` The 3-D velocity of the node: $\mathbf{v}$ [`positionVelocity[X|Y|Z]`].

`positionHistory` The history of the node's position in 6-D phase space, usually used for satellite nodes.

Initialization

None—all properties are assumed to have been preset, usually by the merger tree construction routine.

Differential Evolution

None. Positions and velocities do not evolve for a given node. When output, if a 6-D position history is available than the position and velocity from the history entry closest to the output time will be used[8].

Event Evolution

Node mergers: If `positionsPresetSatelliteToHost=true` then the position and velocity of the satellite node is set equal to that of the host node (this is useful if position data is not available for orphaned halos for example, which would otherwise remain fixed in physical coordinates at their last known position—the position/velocity will also be updated to that of the new host each time a satellite's host changes), otherwise, none.

Satellite merging: None.

Node promotion: The position and velocity are updated to those of the parent node.

11.10. Satellite Orbit

This component tracks the orbital properties of subhalos.

11.10.1. "Preset" Implementation

Properties

The preset satellite orbit implementation defines the following properties:

`mergTime` The time until the satellite will merge with its host: $t_{\rm satellite,merge}$ [`satelliteMergeTime`].

`timeOfMerging` The cosmological time at which the satellite will merge with its host: $T_{\rm satellite,merge}$.

`boundMass` The remaining, total bound mass of the satellite (this property is read only—it is determined from the `boundMassHistory` property).

`boundMassHistory` A history time-series of the total bound mass of the satellite.

`virialOrbit` The orbit (a `keplerOrbit` object; see §16.5.1) of the satellite at virial orbit crossing.

Note that the `mergeTime` and `timeOfMerging` effectively provide the same information. For that reason, setting one of them will automatically set the other accordingly.

Initialization

None. This method assumes that merging times and bound mass histories will be set externally (usually when the merger tree is constructed).

Differential Evolution

None.

[8] While interpolation could be used this is usually a bad idea. For nodes that are satellites in a halo for example, no simple interpolation algorithm can correctly account for the complex orbital dynamics by which the position and velocity is actually evolving.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.10.2. "Very Simple" Implementation

Properties

The simple satellite orbit implementation defines the following properties:

`mergeTime` The time until the satellite will merge with its host: $t_{\text{satellite,merge}}$ [`satelliteMergeTime`].

Initialization

None.

Differential Evolution

Properties are evolved according to:

$$\dot{t}_{\text{satellite,merge}} = -1. \tag{11.89}$$

Event Evolution

Node mergers: The component is created and the time to merging is assigned a value.

Satellite merging: None.

Node promotion: Not applicable (component only exists for satellite nodes).

11.10.3. "Simple" Implementation

Properties

The simple satellite orbit implementation defines the following properties:

`mergeTime` The time until the satellite will merge with its host: $t_{\text{satellite,merge}}$ [`satelliteMergeTime`].

`boundMass` The remaining, total bound mass of the satellite: $M_{\text{node,bound}}$ [`satelliteBoundMass`].

`virialOrbit` The orbit (returned as a `keplerOrbit` object; see §16.5.1) of the satellite at the point of virial radius crossing.

Initialization

None.

Differential Evolution

Properties are evolved according to:

$$\dot{t}_{\rm satellite,merge} = -1, \tag{11.90}$$

with $\dot{M}_{\rm node,bound}$ set to the rate given by the `darkMatterHaloMassLossRateMethod` method (see §16.4.1). The virial orbit is a fixed quantity and does not evolve.

Event Evolution

Node mergers: The component is created and the time to merging is assigned a value. The bound mass is set to the current total mass of the node. If `satelliteOrbitStoreOrbitalParameters=true` then a virial orbit is selected (unless one has already been set for the node) using the `virialOrbitsMethod` (see §12.51.2) and stored (otherwise, a new virial orbit will be computed—possibly at random—each time the virial orbit is requested). If `[satelliteOrbitResetOnHaloFormation]=true` then satellite orbits will be reset on halo formation events (see §11.16).

Satellite merging: None.

Node promotion: Not applicable (component only exists for satellite nodes).

11.10.4. "Orbiting" Implementation

Properties

The orbiting satellite orbit implementation defines the following properties:

`position` The 3-dimensional position of the satellite relative to its host: $\mathbf{r} = (x, y, z)$.

`velocity` The 3-dimensional velocity of the satellite relative to its host: $\mathbf{v} = (v_x, v_y, v_z)$.

`mergeTime` The time until the satellite will merge with its host: $t_{\rm satellite,merge}$ [`satelliteMergeTime`].

`boundMass` The remaining, total bound mass of the satellite: $M_{\rm node,bound}$ [`satelliteBoundMass`].

`virialOrbit` The orbit (returned as a `keplerOrbit` object; see §16.5.1) of the satellite at the point of virial radius crossing.

`tidalTensorPathIntegrated` The time integral of the tidal tensor along the orbit of the satellite from initialization: G_{ij}.

`tidalHeatingNormalized` The tidal heating energy per radius squared desposited into the satellite: $Q_{\rm tidal}$.

Initialization

The satellite position, if not already assigned, is selected such that its magnitude is set according to its virial orbit parameters and its direction is chosen at random assuming an isotropic distribution. The satellite velocity is similarly selected. The integrated tidal tensor, G_{ij}, is initialized to the null tensor, while $Q_{\rm tidal}$ is initialized to zero.

Differential Evolution

Properties are evolved according to:

$$\dot{\mathbf{r}} = \mathbf{v} \tag{11.91}$$

$$\dot{\mathbf{v}} = -\frac{GM_{\rm host}(<r)\mathbf{r}}{r^3}\left(1+\frac{M_{\rm node,bound}}{M_{\rm host}(<r)}\right)+\mathbf{a}_{\rm DF} \tag{11.92}$$

$$\dot{G}_{ij} = g_{ij} - G_{ij}/T_{\rm orb}, \tag{11.93}$$

with $r = |\mathbf{r}|$, $\mathbf{a}_{DF}$ set to the rate given by the `satelliteDynamicalFrictionMethod` (see §12.41), g_{ij} being the tidal tensor, $T_{\rm orb}$ being the satellite's orbital period, $\dot{M}_{\rm node,bound}$ set to the rate given by the `satelliteTidalStrippingMethod` (see §12.43), and $\dot{Q}_{\rm tidal}$ set to the rate given by the `satelliteTidalHeatingMethod` (see §12.44). Note that in the evolution of G_{ij} a decay term is artificially introduced such that the integration of g_{ij} is effectively over just the previous orbit (i.e. over the previous tidal shock).

Event Evolution

Node mergers: The component is created and the time to merging is given a value of -1 to indicate that the satellite is not about to merge as unmerged. Once the satellite satisfies one of the two merging conditions:

$$r < R_{\rm host} + R_{\rm satellite} \tag{11.94}$$

$$M_{\rm node,bound} < f_{\rm d} M_{\rm node,basic}, \tag{11.95}$$

with R being the node's half-mass radius, $M_{\rm node,basic}$ being the node's initial mass, and $f_{\rm d}$ =`[satelliteOrbitingDestruction` the node is considered merged and the time to merging is set to zero. The bound mass is set to the current total mass of the node. A virial orbit is selected using the `virialOrbitsMethod` (see §12.51.2).

Satellite merging: None.

Node promotion: Not applicable (component only exists for satellite nodes).

11.11. N-body Halo Properties

This component is intended for tracking of miscellaneous properties derived from N-body simulation merger trees.

11.11.1. "Standard" Implementation

Properties

The standard N-body component implementation defines the following properties:

`particleCount` The number of particles in the N-body halo [`nbodyParticleCount`].

`velocityMaximum` The maximum of the N-body halo's rotation curve (in units of km/s) [`nbodyVelocityMaximum`].

`velocityDispersion` The velocity dispersion of the N-body halo (in units of km/s) [`nbodyVelocityDispersion`].

Initialization

The N-body properties of each node are assumed to have been preset prior to merger tree initialization. They are assumed to remain constant along each branch of the tree.

Differential Evolution

None.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: The properties are updated to equal those of the parent node.

11.12. Dark Matter Halo Spin

11.12.1. "Random" Implementation

Properties

The random dark matter halo spin implementation defines the following properties:

`spin` The spin parameter of the halo: λ [`spinSpin`].

Initialization

The spin parameter of each node, if not already assigned, is selected at random from a distribution of spin parameters. This value is assigned to the earliest progenitor of the halo traced along its primary branch. The value is then propagated forward along the primary branch until the node mass exceeds that of the node for which the spin was selected by a factor of `[randomSpinResetMassFactor]`, at which point a new spin is selected at random, and the process repeated until the end of the branch is reached.

Differential Evolution

The spin parameter does not evolve.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: The spin is updated to equal that of the parent node. (The two will differ only if this is a case where the new halo node was sufficiently more massive than the node for which a spin was last selected that a new spin value was chosen.)

11.12.2. "Preset" Implementation

Properties

The preset dark matter halo spin implementation defines the following properties:

`spin` The spin parameter of the halo: λ [`spinSpin`].

`spinGrowthRate` The growth rate spin parameter of the halo (in units of Gyr^{-1}).

Initialization

The spin parameter of each node is assumed to have been preset prior to merger tree initialization. The growth rate is computed assuming linear growth with time along each branch.

Differential Evolution

The spin parameter evolves linearly with time between node and parent node.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: The spin and growth rate are updated to equal those of the parent node.

11.12.3. "Preset3D" Implementation

The type extends the `preset` spin component implementation, and so provides all properties of that implementation plus those described below.

Properties

The preset dark matter halo spin implementation defines the following properties:

`spinVector` The spin vector of the halo: λ [`spinSpinVector`].

`spinVectorGrowthRate` The growth rate of the spin vector of the halo (in units of Gyr^{-1}).

Initialization

The spin vector of each node is assumed to have been preset prior to merger tree initialization. The growth rate is comptued assuming linear growth with time along each branch.

Differential Evolution

The spin parameter evolves linearly with time between node and parent node.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: The spin vector and growth rate are updated to equal those of the parent node.

11.12.4. "Vitvitska Implementation

Properties

The Vitvitska dark matter halo spin implementation follows the Vitvitska et al. [2002] model for halo spins, and defines the following properties:

`spin` The spin parameter of the halo: λ [`spinSpin`].

Initialization

The spin parameters of nodes having no children are drawn at random from the selected spin distribution function. For other nodes, their angular momentum is set equal to the sum of the spin angular momentum of their primary progenitor and the orbital angular momenta of all non-primary progenitors (which are determined from the orbital parameters) modulated by a factor dependent on the mass ratio of the merging halos:

$$\mathbf{J}^{(\mathrm{spin})}_{\mathrm{parent}} = \mathbf{J}^{(\mathrm{spin})}_{1} + \sum_{i=2}^{N} \left(1 + \frac{m_i}{m_1}\right)^{-\alpha} \mathbf{J}^{(\mathrm{orbit})}_{i}. \tag{11.96}$$

where $\alpha =$ [`spinVitvitskaMergerRatioExponent`].

Differential Evolution

The spin parameter does not evolve.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.13. Dark Matter Profile

This component stores dynamic properties associated with dark matter halo density profiles.

11.13.1. "Scale" Implementation

Properties

The scale dark matter profile implementation defines the following properties:

`scale` The scale length of the density profile [`darkMatterProfileScale`];

`scaleGrowthRate` The growth rate of the scale length of the density profile.

Initialization

The scale length of each node, if not already assigned, is assigned using the concentration parameter function (see §12.11.3), but is not allowed to drop below `[darkMatterProfileMinimumConcentration]`, such that the scale length is equal to the virial radius divided by that concentration.

Differential Evolution

The scale radius grows linearly with time to interpolate between the scale radii of child and parent halos.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.13.2. "Scale Preset" Implementation

Properties

The "scale preset" dark matter profile implementation defines the following properties:

`scale` The scale length of the density profile [`darkMatterProfileScale`];

`scaleGrowthRate` The growth rate of the scale length of the density profile.

Initialization

The scale length of each node is assumed to be assigned udirng tree construction.

Differential Evolution

The scale radius grows linearly with time to interpolate between the scale radii of child and parent halos.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.13.3. "Scale+Shape" Implementation

Properties

The scale+shape dark matter profile implementation defines the following properties:

`scale` The scale length of the density profile [`darkMatterProfileScale`];

`scaleGrowthRate` The growth rate of the scale length of the density profile.

`shape` A shape parameter describing the density profile [`darkMatterProfileShape`];

`shapeGrowthRate` The growth rate of the shape parameter of the density profile.

Initialization

The scale length of each node, if not already assigned, is assigned using the concentration parameter function (see §12.11.3), but is not allowed to drop below `[darkMatterProfileMinimumConcentration]`, such that the scale length is equal to the virial radius divided by that concentration. The shape parameter of each node is assigned using the dark matter profile shape function (see §16.4.1).

Differential Evolution

The scale radius and shape parameter of each node grow linearly with time to interpolate between the scale radii and shape parameters of child and parent halos.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.14. Merging Statistics

This component records statistics associated with galaxy merging.

11.14.1. "Standard" Implementation

Properties

The standard merging statistics implementation defines the following properties:

`galaxyMajorMergerTime` The time of the last major merger associated with this galaxy, output as the time *since* the last major merger [`mergingStatisticsGalaxyMajorMergerTime`];

`nodeMajorMergerTime` The time of the last major merger (as defined by the `[nodeMajorMergerFraction]` parameter) between this node and another, output as the time *since* the last major merger [`mergingStatisticsNodeMajo`

`nodeFormationTime` The time at which the node is judged to have "formed", defined as the time at which its main branch progenitor had a mass equal to a fraction `[nodeFormationMassFraction]` of the node's initial mass in the merger tree [`mergingStatisticsNodeFormationTime`];

`nodeHierarchyLevel` The depth of this node in the initial merger tree hierarchy. For example, a node on the main branch has level 0. A node which merges directly onto the main branch has level 1. A node that merges onto a node that merges directly onto the main branch has level 2, etc. [`mergingStatisticsNodeHierarchyLevel`];

Initialization

The times of the last mergers are stored each time a major merger occurrs and this component is created (if necessary) the first time such a merger occurs. Formation times and hierarchy levels are computed during merger tree initialization.

Differential Evolution

The times of the last mergers do not evolve.

Event Evolution

Node mergers: The time of the last node merger in the parent node is reset to the current time if the merger is major.

Satellite merging: The time of the last merger is reset to the current time if the merger is major.

Node promotion: The time of the last major node merger is updated to that of the parent if that time is more recent.

11.14.2. "Recent" Implementation

Properties

The recent merging statistics implementation defines the following properties:

`recentMajorMergerTime` The number of node major mergers (defined as a merger with mass ratio in excess of [`nodeMajorMergerFraction`]) occuring within a recent interval, Δt where $\Delta t =$ [`nodeRecentMajorMergerInterv` if [`nodeRecentMajorMergerIntervalType`]=`absolute`, or $\Delta t =$ [`nodeRecentMajorMergerInterval`] $\tau_{\rm dyn}$ (where $\tau_{\rm dyn}$ is the halo dynamical time) if [`nodeRecentMajorMergerIntervalType`]=`dynamical`. [`mergingStatisticsRecentMajorMergerTime`];

Initialization

The number of recent mergers for each output time are initialized to zero.

Differential Evolution

The number of recent mergers do not evolve.

Event Evolution

Node mergers: If the merger is major and occurs within Δt of an output time, the number of recent major mergers is increased by one.

Satellite merging: N/A.

Node promotion: N/A.

11.14.3. "Major" Implementation

Properties

The major merging statistics implementation defines the following properties:

`majorMergerTime` The time(s) of galaxy major mergers experience by this node. If non-empty, the merger times are output to a dataset `majorMergers/Output<O>/mergerTree<T>/node<N>` (where `<O>` is the output number, `<T>` is the tree index, and `<N>` is the node index) in the GALACTICUS output file.

Initialization

The times are initialized to an empty list.

Differential Evolution

N/A.

Event Evolution

Node mergers: N/A.

Satellite merging: If the merger is major, the time of the merger is appended to the list of merging times for the host node.

Node promotion: Times recorded from the parent node are appended to those of the child node prior to promotion.

11.15. Age Statistics

This component records statistics associated with galaxy or halo age.

11.15.1. "Standard" Implementation

Properties

The standard age statistics implementation defines the following properties:

`(disk|spheroid)TimeWeightedIntegratedSFR` A time-weighted integral over the star formation rate of the specified component [`ageStatistics(Disk|Spheroid)TimeWeightedIntegratedSFR`];

`(disk|spheroid)IntegratedSFR` A unweighted integral over the star formation rate of the specified component [`ageStatistics(Disk|Spheroid)IntegratedSFR`];

Initialization

The integrals are all initialized to zero.

Differential Evolution

The time-weighted integrals evolve as:

$$\frac{\mathrm{d}(M\tau)_\star}{\mathrm{d}t} = t\phi(t), \tag{11.97}$$

where t is cosmic time and $\phi(t)$ is the star formation rate in the component. The unweighted integrals evolve as:

$$\frac{\mathrm{d}M_\star}{\mathrm{d}t} = \phi(t). \tag{11.98}$$

The mean cosmic time of formation for the stars in either component can be found by taking the ratio of time-weighted to unweighted integrals. The mean age can then be found by subtracting the mean cosmic time of formation from the present time.

Event Evolution

Node mergers: N/A.

Satellite merging: The values of the integrals are removed from the merging galaxy and transferred to the appropriate component of the target galaxy. Additionally, in a major merger, the values of the integral are transferred between components in the target galaxy as dictated by the merging rules.

Node promotion: N/A.

11.16. Formation Times

This component implements "formation times" of dark matter halos.

11.16.1. "Cole2000" Implementation

Properties

The "Cole2000' formation times implementation defines the following properties:

`formationTime` The time at which the halo last "formed". Formation is defined as an increase in the mass of the halo by a factor `[haloReformationMassFactor]`.

Initialization

The formation time is set to the current time and this component is created the first time such a merger occurs.

Differential Evolution

The formation time does not evolve. When the node mass exceeds the mass at the formation time by a factor `[haloReformationMassFactor]` evolution is interrupted and the formation time reset to the current time.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.17. Indices

This component tracks various indices associated with nodes.

11.17.1. "Standard" Implementation

Properties

The "standard' indices implementation defines the following properties:

`branchTip` The index of the node at the tip of the branch to which the node belongs.

Initialization

The branch tip index is set to equal the index of each branch tip node in the tree.

Differential Evolution

The indices do not evolve.

Event Evolution

Node mergers: None.

Satellite merging: None.

Node promotion: None.

11.18. Inter-Output Quantities

This component tracks various quantities averaged between successive outputs.

11.18.1. "Standard" Implementation

Properties

The "standard' inter-output implementation defines the following properties:

`diskStarFormationRate` The mean star formation rate (in units of $M_\odot$ Gyr^{-1}) in the disk between the previous and current output times.

`spheroidStarFormationRate` The mean star formation rate (in units of $M_\odot$ Gyr^{-1}) in the spheroid between the previous and current output times.

Initialization

No initialization is carried out—component is created as needed.

Differential Evolution

The disk and spheroid star formation rates, $\langle \dot{M}_\star \rangle$, evolve according to:

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle \dot{M}_\star \rangle = \frac{\dot{M}_\star}{\Delta t}, \tag{11.99}$$

where $\dot{M}_\star$ is the instantaneous star formation rate in the corresponding component and Δt is the time between the previous and next output times.

Event Evolution

Node mergers: None.

Satellite merging: The mean star formation rates from the satellite are added to those of the parent.

Node promotion: None.

Output: All quantities are zeroed after each output.

12. Physical Implementations

12.1. Analytic Solvers

Galacticus typically solves the system of ODEs which describe the evolution of a galaxy using a numerical solver. However, in some situations analytic solutions may be available. Galacticus allows for the use of analytic solvers in such cases. Currently available analytic solvers are described below.

12.1.1. Simple Disk Satellites

This solver, which can be activated by setting `[diskVerySimpleUseAnalyticSolver]=true` is applicable to satellite systems in the very simple disk component. In particular, the following conditions must be met for it to be valid:

- The hot halo component must be of type `verySimple` or `verySimpleDelayed`;
- The satellite component must be of type `verySimple`;
- The disk component must be of type `verySimple`;
- Properties of all other components must not change for satellite galaxies (with the exception of the `time` property of the basic component), or else the component must be `null`;
- Disk star formation and outflow rates must scale as $M_{\rm gas}/\tau$ where $M_{\rm gas}$ is the instantaneous mass of gas in the galaxy disk, and τ is a fixed timescale for any given satellite galaxy.

Under these conditions, the flow of mass between gas, stellar, and outflowed phases is analytically solvable.

12.2. Accretion of Gas into Halos

The accretion rate of gas from the IGM into a dark matter halo is expected to depend on (at least) the rate at which that halo mass is growing, the depth of its potential well and the thermodynamical properties of the accreting gas. Galacticus implements the following calculations of gas accretion from the IGM, which can be selected via the `accretionHaloMethod` input parameter.

12.2.1. Simple

Selected using `accretionHaloMethod=simple`, this method sets the accretion rate of baryons into a halo to be:

$$\dot{M}_{\rm accretion} = \begin{cases} (\Omega_{\rm b}/\Omega_{\rm M}) \dot{M}_{\rm halo} & \text{if } V_{\rm virial} > V_{\rm reionization} \text{ or } z > z_{\rm reionization} \\ 0 & \text{otherwise,} \end{cases} \tag{12.1}$$

where $z_{\rm reionization}$ = `[reionizationSuppressionRedshift]` is the redshift at which the Universe is reionized and $V_{\rm reionization}$ = `[reionizationSuppressionVelocity]` is the virial velocity below which accretion is suppressed after reionization. Setting $V_{\rm reionization}$ to zero will effectively switch off the effects of reionization on the accretion of baryonics. This algorithm attempts to offer a simple prescription for the effects of reionization and has been explored by multiple authors (e.g. Benson et al. 2002). In particular, Font

et al. [2010] show that it produces results in good agreement with more elaborate treatments of reionization. For halos below the accretion threshold, any accretion rate that would have otherwise occurred is instead placed into the "failed" accretion rate. For halos which can accrete, and which have some mass in their "failed" reservoir, that mass will be added to the regular accretion rate at a rate equal to the mass of the "failed" reservoir times the specific growth rate of the halo. The gas accreted is assumed to be from a pristine IGM and so has zero abundances. Chemical abundances are computed from the chemical state functions (see §12.30).

Note that, if $\dot{M}_{\rm halo} < 0$ then negative accretion rates of gas into the node can result. This ccan be prevented by setting `[accretionHalosSimpleNegativeAccretionAllowed]`=`false`.

By default, gas is accreted whenever the halo is growing in total mass. However, setting `[accretionHalosSimpleAccreteNe` causes accretion to occur only if the node mass is growing and exceeds the previous maximum node mass achieved along this branch of the merger tree. This requires use of a basic component which tracks the maximum mass along the branch (i.e. the `massMaximum` property).

12.2.2. Null

Selected using `accretionHaloMethod`=`null`, this method sets the accretion rate of baryons into a halo to be zero always.

12.2.3. Cold Mode

Selected using `accretionHaloMethod`=`coldMode`, this class extends the `simple` class by dividing the accretion into hot and cold mode components. The cold mode fraction follows the approximation introduced by Benson and Bower [2010], namely:

$$f_{\rm cold} = (1 + r^{1/\delta})^{-1}, \tag{12.2}$$

where $\delta =$ `[accretionColdModeShockStabilityTransitionWidth]`, $r = \epsilon_{\rm crit}/\epsilon$, and

$$\epsilon = r_{\rm s}\Lambda/\rho_{\rm s}v_{\rm s}^3, \tag{12.3}$$

where $r_{\rm s}$ is the accretion shock radius, Λ is the post-shock cooling function, $\rho_{\rm s}$ is the pre-shock density, $v_{\rm s}$ is the pre-shock velocity, and $\epsilon_{\rm crit} =$ `[accretionColdModeShockStabilityThreshold]`. The pre-shock radius is set equal to the halo virial radius, the pre-shock velocity is set equal to the halo virial velocity, while the pre-shock density is given by

$$\rho_{\rm s} = \frac{\gamma-1}{\gamma+1}\frac{3}{4\pi}\frac{\Omega_{\rm b}}{\Omega_{\rm m}}\frac{M}{r_{\rm s}^3}\left[1+\frac{(\alpha+3)(10+9\pi)}{4}\right]^{-1}, \tag{12.4}$$

where M is the total halo mass, $\gamma(=5/3)$ is the adiabatic index of the gas, and α is the exponent of the initial power-law density perturbation ($\alpha = 0$ is assumed). The post-shock density and temperature are found assuming the strong-shock limit.

12.2.4. Naoz & Barkana (2007)

Selected using `accretionHaloMethod`=`naozBarkana2007` this method uses the filtering mass prescription of Naoz and Barkana [2007] to compute the accreted rate of baryonic material. Specifically, Naoz and Barkana [2007] assume that the gas mass content of halos is given by $M_{\rm g}(M_{\rm 200b}, M_{\rm F}) = (\Omega_{\rm b}/\Omega_{\rm M})f(M_{\rm 200b}/M_{\rm F})M_{\rm 200b}$ where $M_{\rm F}$ is the filtering mass, as first introduced by Gnedin [2000] but defined following Naoz and Barkana [2007], $M_{\rm 200b}$ is the halo mass defined by a density threshold of 200 times the mean background, and

$$f(x) = [1 - (2^{1/3} - 1)x^{-1}]^{-3}. \tag{12.5}$$

The accretion rate onto the halo is therefore assumed to be

$$\dot{M}_\mathrm{g} = \frac{\Omega_\mathrm{b}}{\Omega_\mathrm{M}} \frac{\mathrm{d}}{\mathrm{d}M_\mathrm{200b}} \left[f(M_\mathrm{200b}/M_\mathrm{F}) M_\mathrm{200b} \right] \dot{M}_\mathrm{total}. \tag{12.6}$$

This would result in a precise match to the Naoz and Barkana [2007] assumption if:

1. The filtering mass is constant in time;
2. M_total corresponds to M_200b; and
3. The growth of halos occurs through smooth accretion, not through merging of smaller halos.

In practice all three assumptions are violated. As such, the mass fraction in the halo will differ from $f(M_\mathrm{200b}/M_\mathrm{F})$. To address this issue, mass is additionally assumed to flow from the hot halo reservoir to the unaccreted mass reservoir at a rate:

$$\dot{M}_\mathrm{hot} = -\frac{\alpha_\mathrm{adjust}}{\tau_\mathrm{dyn}} [M_\mathrm{hot} + M_\mathrm{unaccreted}][f_\mathrm{accreted} - f(M_\mathrm{200b}/M_\mathrm{F})], \tag{12.7}$$

where α_adjust =[`accretionHaloNaozBarkana2007RateAdjust`].

12.3. Accretion of Total Mass into Halos

The accretion rate of total mass (i.e. the mass which would be accreted in a dark matter-only universe) can be computed by the following options, which can be selected via the `accretionHaloTotalMethod` input parameter.

12.3.1. Simple

Selected using `accretionHaloTotalMethod=simple`, this class assumes that the accretion rate is equal to the growth rate of the basic component mass property.

12.3.2. Bertschinger

Selected using `accretionHaloTotalMethod=bertschinger`, this class assumes that the accretion rate is equal to the growth rate of the basic component Bertschinger mass property.

12.4. Cosmology Functions

The background cosmology describes the evolution of an isotropic, homoegeneous Universe within which our calculations are carried out. For the purposes of Galacticus, the background cosmology is used to relate expansion factor/redshift to cosmic time and to compute the density of various components (e.g. dark matter, dark energy, etc.) at different epochs. Background cosmological models are specified via the `cosmologyMethod`, and the physics that must be implemented for each cosmological model is describe in more detail in §16.4.1. Currently implemented cosmological models are as follows.

12.4.1. Matter + Lambda

Selected with `cosmologyMethod=matter-lambda`, in this implementation cosmological relations are computed assuming a universe that contains only collisionless matter and a cosmological constant.

12.4.2. Matter + Dark Energy

Selected with `cosmologyMethod=matter-darkEnergy`, in this implementation cosmological relations are computed assuming a universe that contains only collisionless matter and dark energy with an equation of state $w(a) = w_0 + w_1 a(1-a)$ [Jassal et al., 2005], with $w_0 =$`[darkEnergyEquationOfStateW0]`, and $w_1 =$`[darkEnergyEquationOfStateW1]`.

12.5. Circumnuclear Accretion Disks

Circumnuclear accretion disks surrounding supermassive black holes at the centers of galaxies influence the evolution of both the black hole (via accretion rates of mass and angular momentum and possibly by extracting rotational energy from the black hole) and the surrounding galaxy if they lead to energetic outflows (e.g. jets) from the nuclear region. Accretion disk type is specified via the `accretionDisksMethod`, and the physics that must be implemented for each accretion disk type is describe in more detail in §16.4.1. Current implementations of accretion disks are as follows.

12.5.1. Shakura-Sunyaev Geometrically Thin, Radiatively Efficient Disks

Selected with `accretionDisksMethod=Shakura-Sunyaev`, this implementation assumes that accretion disks are always described by a radiatively efficient, geometrically thin accretion disk as described by Shakura and Sunyaev [1973]. The radiative efficiency of the flow is computed assuming that material falls into the black hole without further energy loss from the innermost stable circular orbit (ISCO), while the spin-up rate of the black hole is computed assuming that the material enters the black hole with the specific angular momentum of the ISCO (i.e. there are no torques on the material once it begins to fall in from the ISCO; Bardeen 1970). For these thin disks, jet power is computed, using the expressions from Meier (2001; his equations 4 and 5).

12.5.2. Advection Dominated, Geometrically Thick, Radiatively Inefficient Flows (ADAFs)

Selected with `accretionDisksMethod=ADAF`, this implementation assumes that accretion is via an advection-dominated accretion flow (ADAF) [Narayan and Yi, 1994] which is radiatively inefficient and geometrically thick. The radiative efficiency of the flow, which will be zero for a pure ADAF, is controlled by `[adafRadiativeEfficiencyType]`. If set to `fixed`, then the radiative efficiency is set to the value of the input parameter `[adafRadiativeEfficiency]`. Alternatively, if set to `thinDisk` the radiative efficiency will be set to that of a Shakura-Sunyaev thin disk. The spin up rate of the black hole and the jet power produced as material accretes into the black hole are computed using the method of Benson and Babul [2009]. The maximum efficiency of the jet (in units of the accretion power $\dot{M}c^2$) is set by `[adafJetEfficiencyMaximum]`—in the model of Benson and Babul [2009] the jet efficiency diverges as $j \rightarrow 1$, setting a maximum is important to avoid numerical instabilities. The energy of the accreted material can be set equal to the energy at infinity (as expected for a pure ADAF) or the energy at the ISCO by use of the `[adafEnergyOption]` parameter (set to `pureADAF` or `ISCO` respectively). The ADAF structure is controlled by the adiabatic index, γ, and viscosity parameter, α, which are specified via the `[adafAdiabaticIndex]` and `[adafViscosityOption]` input parameters respectively. The field-enhancing shear, g, is computed using $g = \exp(\omega\tau)$ if `[adafFieldEnhanceType]` is set to "exponential" where ω is the frame-dragging frequency and τ is the smaller of the radial inflow and azimuthal velocity timescales. If `[adafFieldEnhanceType]` is set to "linear" then the alternative version, $g = 1 + \omega\tau$ is used instead. `[adafViscosityOption]` may be set to "`fit`", in which case the fitting function for α as a

function of black hole spin is used:

$$\alpha(j) = 0.015 + 0.02j^4 \quad \text{if} \quad g = \exp(\omega\tau) \text{ and } E = E_{\rm ISCO}, \tag{12.8}$$
$$\alpha(j) = 0.025 + 0.08j^4 \quad \text{if} \quad g = 1 + \omega\tau \text{ and } E = E_{\rm ISCO}, \tag{12.9}$$
$$\alpha(j) = 0.010 + 0.00j^4 \quad \text{if} \quad g = \exp(\omega\tau) \text{ and } E = 1, \tag{12.10}$$
$$\alpha(j) = 0.025 + 0.02j^4 \quad \text{if} \quad g = 1 + \omega\tau \text{ and } E = 1. \tag{12.11}$$

12.5.3. "Switched" Disks

Selected with `accretionDisksMethod=switched`, this method allows for accretion disks to switched between radiatively efficient (Shakura-Sunyaev) and inefficient (ADAF) modes. This is intended to crudely model the fact that accretion disks are expected to be radiatively inefficient at both high accretion rates (i.e. as they approach the Eddington luminosity the radiation pressure from a radiatively efficient flow would begin to disrupt the flow itself by definition), while accretion flows at low accretion rates ($\dot{M}_{\rm acc} < \alpha^2 \dot{M}_{\rm Edd}$, where $\alpha \sim 0.1$ is the usual parameter controlling the rate of angular momentum transport in a Shakura and Sunyaev [1973] accretion disk) are also radiatively inefficient as radiative processes are too inefficient at the associated low densities to radiate energy at the rate it is being liberated. A more thorough discussion is given by Begelman [2014].

The properties of the switched disk (e.g. radiative efficiency, jet power), are a linear combination of those of the Shakura-Sunyaev and ADAF modes, with the ADAF fraction being given by:

$$f_{\rm ADAF} = [1 + \exp(y_{\rm min})]^{-1} + [1 + \exp(y_{\rm max})]^{-1}, \tag{12.12}$$

where

$$y_{\rm min} = +\log(x/x_{\rm min})/\Delta_x, \tag{12.13}$$
$$y_{\rm max} = -\log(x/x_{\rm max})/\Delta_x, \tag{12.14}$$

and,

$$x = \dot{M}/\dot{M}_{\rm Eddington}. \tag{12.15}$$

Here, $x_{\rm min}$ =`[accretionRateThinDiskMinimum]`, $x_{\rm max}$ =`[accretionRateThinDiskMaximum]`, and Δ_x=`[accretionRateTra` If either `[accretionRateThinDiskMinimum]` or `[accretionRateThinDiskMaximum]` is set to "`none`" then the corresponding term in eqn. (12.12) is excluded.

Additionally, if `[accretionDiskSwitchedScaleAdafRadiativeEfficiency]` is set to `true` then the radiative efficiency of the ADAF component is reduced by a factor $x/x_{\rm min}$ when $x < x_{\rm min}$.

12.5.4. Eddington-limited Disks

Selected with `accretionDisksMethod=eddingtonLimited`, this method does not assume any physical model for the accretion disk, but merely assumes that jets are powered at a fixed fraction `[accretionDiskJetPowerEddington` of the Eddington luminosity. The radiative efficiency is similarly set at a fixed value of `[accretionDiskRadiativeEfficiency` Since no physical model for the disk is assumed, the black hole spin up rate is always set to zero.

12.6. Dark Matter Structure Formation

A variety of functions are used to describe structure formation in dark matter dominated universes. These are described below.

12.6.1. Primordial Power Spectrum

The functional form of the primordial dark matter power spectrum is selected via the `powerSpectrumMethod` parameter. The power spectrum is computed from the specified primordial power spectrum and the transfer function (see §16.4.1) and normalized to a value of σ_8 specified by `[sigma_8]`.

(Running) Power Law Spectrum

Selected via `powerSpectrumMethod=powerLaw`, this method implements a primordial power spectrum of the form:

$$P(k) \propto k^{n_{\rm eff}(k)}, \tag{12.16}$$

where

$$n_{\rm eff}(k) = n_{\rm s} + \frac{1}{2}\frac{{\rm d}n}{{\rm d}\ln k}\ln\left(\frac{k}{k_{\rm ref}}\right), \tag{12.17}$$

where $n_{\rm s}$ =`[index]` is the power spectrum index at wavenumber $k_{\rm ref}$ =`[wavenumberReference]` and ${\rm d}n/{\rm d}\ln k$ =`[running]` describes the running of this index with wavenumber.

12.6.2. Cosmological Mass Root Variance

The method used to compute the root variance of the cosmological mass field, $\sigma(M)$, is selected via the `cosmologicalMassVarianceMethod` parameter.

Filtered Power Spectrum

Selected via `cosmologicalMassVarianceMethod=filteredPowerSpectrum`, this method computes the mass root variance using:

$$\sigma^2(M) = \frac{1}{2\pi^2}\int_0^\infty P(k)T^2(k)W^2(k)k^2{\rm d}k \tag{12.18}$$

where $P(k)$ is the primordial power spectrum (see §12.6.1), $T(k)$ is the transfer function (see §12.6.5), and $W(k)$ is the power spectrum variance window function (see §12.6.3).

12.6.3. Power Spectrum Variance Window Function

The functional form of the window function used in computing the variance of the power spectrum is selected via the `powerSpectrumWindowFunctionMethod` parameter. Note that when computing the normalization of the power spectrum to match the specified value of σ_8 a top-hat real-space window function is *always* used (as per the definition of σ_8).

Top-hat

Selected via `powerSpectrumWindowFunctionMethod=topHat`, this method implements a top-hat window function in real-space:

$$W(k) = \frac{3(\sin(x) - x\cos(x))}{x^3}, \tag{12.19}$$

where $x = kR$ and $R = (3M/4\pi\bar{\rho})^{1/3}$ for a smoothing scale M and mean matter density $\bar{\rho}$.

Sharp in k-space

Selected via `powerSpectrumWindowFunctionMethod=kSpaceSharp`, this method implements a top-hat window function in k-space:

$$W(k) = \begin{cases} 1 & \text{if } k < k_\mathrm{s} \\ 0 & \text{if } k > k_\mathrm{s}, \end{cases} \tag{12.20}$$

where if `[powerSpectrumWindowFunctionSharpKSpaceNormalization]=natural` then $k_\mathrm{s} = (6\Pi^2\bar{\rho}/M)^{1/3}$ for a smoothing scale M and mean matter density $\bar{\rho}$. Otherwise, `[powerSpectrumWindowFunctionSharpKSpaceNormalizatio` must be set to a numerical value, α, in which case $k_\mathrm{s} = \alpha/R_\mathrm{th}$ with $R_\mathrm{th} = 3M/4\pi\bar{\rho}$ for a smoothing scale M and mean matter density $\bar{\rho}$.

Hybrid of Top-hat and Sharp in k-space

Selected via `powerSpectrumWindowFunctionMethod=topHatKSpaceSharpHybrid`, this method implements a convolution of a top-hat window function and sharp k-space window function in k-space:

$$W(k) = W_\mathrm{th}(k)W_\mathrm{s}(k), \tag{12.21}$$

where

$$W(k) = \frac{3(\sin(x) - x\cos(x))}{x^3}, \tag{12.22}$$

where $x = kR_\mathrm{th}$, and

$$W_\mathrm{s}(k) = \begin{cases} 1 & \text{if } k < k_\mathrm{s} \\ 0 & \text{if } k > k_\mathrm{s}, \end{cases} \tag{12.23}$$

where $ks = \alpha/R_\mathrm{s}$ if `[powerSpectrumWindowFunctionSharpKSpaceNormalization]` is assigned a numerical value. Alternatively, if `[powerSpectrumWindowFunctionSharpKSpaceNormalization]=natural` then the value of α is chosen such that $k_\mathrm{s} = (6\Pi^2\bar{\rho}/M)^{1/3}$ if $R_\mathrm{s} = 3M/4\pi\bar{\rho}$.

The radii, R_th and R_s, are chosen such that:

$$R_\mathrm{th}^2 + R_\mathrm{s}^2 = (3M/4\pi\bar{\rho})^{2/3} \tag{12.24}$$

$$R_\mathrm{s} = \beta R_\mathrm{th}, \tag{12.25}$$

where $\beta =$`[powerSpectrumWindowFunctionSharpKSpaceTopHatRadiiRatio]`.

12.6.4. Non-linear Matter Power Spectrum

The non-linear matter power spectrum method is selected via the `powerSpectrumNonlinearMethod` parameter.

Linear

Selected via `powerSpectrumNonlinearMethod=linear`, this method simply returns the linear matter power spectrum. It is intended primarily for testing purposes.

Peacock & Dodds (1996)

Selected via `powerSpectrumNonlinearMethod=peacockDodds1996`, this method usese the fitting function of Peacock and Dodds [1996] to compute the non-linear matter power spectrum.

CosmicEmu

Selected via `powerSpectrumNonlinearMethod=cosmicEmu`, this method usese the cosmic emulator ("CosmicEmu") code of Lawrence et al. [2010] to evaluate the non-linear matter power spectrum. The CosmicEmu code will be downloaded, compiled and run as necessary if this option is utilized.

12.6.5. Transfer Function

The functional form of the cold dark matter transfer function is selected via the `transferFunctionMethod` parameter. The power spectrum is computed from the specified transfer function and the primordial power spectrum (see §12.6.1) and normalized to a value of σ_8 specified by `[sigma_8]`.

Null

Selected with `transferFunctionMethod=null`, this method assumes $T(k) = 1$ for all k.

BBKS

Selected with `transferFunctionMethod=BBKS`, this method uses the fitting function of Bardeen et al. [1986] to compute the CDM transfer function. The BBKS warm dark matter transfer function can be used by specifying the appropriate streaming length (in Mpc) via the `[transferFunctionWDMFreeStreamingLength]` parameter.

Eisenstein & Hu

Selected with `transferFunctionMethod=Eisenstein-Hu1999`, this method uses the fitting function of Eisenstein and Hu [1999] to compute the CDM transfer function. It requires that the effective number of neutrino species be specified via the `effectiveNumberNeutrinos` parameter and summed mass of all neutrino species (in eV) be specified via the `summedNeutrinoMasses` parameter. Additionally, the transfer function can be modified to model warm dark matter using the fitting function given by Barkana et al. [2001]:

$$T(k) \rightarrow T(k)(1 + [\epsilon k R_{\rm c}^0]^{2\nu})^{-\eta/\nu}, \tag{12.26}$$

where $R_{\rm c}^0 =$`[transferFunctionWdmCutOffScale]`, $\epsilon =$`[transferFunctionWdmEpsilon]`, $\eta =$`[transferFunctionWdmEta]`, $\nu =$`[transferFunctionWdmNu]`.

CAMB

Selected with `transferFunctionMethod=CAMB`, this method uses the CAMB code to compute the CDM transfer function. It requires that the mass fraction of helium in the early Universe be specified via the `Y_He` parameter. CAMB will be downloaded and run if the transfer function needs to be computed. It will then be stored in a file for future reference.

File

Selected with `transferFunctionMethod=file`, this method reads a tabulated transfer function from an XML file (specified via the `transferFunctionFile` parameter), interpolating between tabulated points. The structure of the transfer function file is described in §16.4.1.

12.6.6. Linear Growth Function

The function describing the amplitude of linear perturbations is selected via the `linearGrowthMethod` parameter.

Simple

Selected with `linearGrowthMethod=simple`, this method calculates the growth of linear perturbations using standard perturbation theory in a Universe consisting of matter and a cosmological constant. Perturbations in the baryons are treated just as for dark matter (i.e. pressure forces are ignored), while perturbations in the radiation are assumed not to grow.

12.6.7. Critical Overdensity

The method used to compute the critical linear overdensity at which overdense regions virialize is selected via the `criticalOverdensityMethod` parameter.

Spherical Collapse (Matter + Cosmological Constant)

Selected with `criticalOverdensityMethod=sphericalTopHat` this method calculates critical overdensity using a spherical top-hat collapse model assuming a Universe which contains matter and a cosmological constant (see, for example, Percival 2005).

Kitayama & Suto (1996)

Selected with `criticalOverdensityMethod=Kitayama-Suto1996` this method calculates critical overdensity using the fitting formula of Kitayama and Suto [1996], and so is valid only in flat cosmological models (an error will be reported in non-flat models). Specifically,

$$\delta_{\rm crit}(t) = \frac{3(12\pi)^{2/3}}{20}[1 + 0.0123 \log_{10}\{\Omega_{\rm matter}(t)\}]/D(t). \tag{12.27}$$

Fixed

Selected with `criticalOverdensityMethod=fixed` this method sets the critical overdensity equal to a fixed value (set via the parameter `[criticalOverdensityFixed]`) divided by the linear growth factor.

12.6.8. Critical Overdensity Mass Scaling

The method used to compute the scaling with mass of the critical linear overdensity at which overdense regions virialize is selected via the `criticalOverdensityMassScalingMethod` parameter.

Null

Selected with `criticalOverdensityMassScalingMethod=null` this method assumes that the critical overdensity is independent of mass.

Warm Dark Matter

Selected with `criticalOverdensityMassScalingMethod=warmDarkMatter` this method assumes that the critical overdensity scales with mass as expected for warm dark matter using the results of Barkana et al. [2001]. Specifically, the critical overdensity is multiplied by a factor

$$\exp\left[\left(\frac{M_{\rm J}}{8M}\right)^{1.40} + \left(\frac{M_{\rm J}}{8M}\right)^{0.45}\right], \tag{12.28}$$

where M is the mass in question, M_J is the effective Jeans mass of the warm dark matter as defined by Barkana et al. [2001; their eqn. 10]:

$$M_\mathrm{J} = 3.06 \times 10^8 \left(\frac{1+z_\mathrm{eq}}{3000}\right)^{1.5} \left(\frac{\Omega_\mathrm{M} h_0^2}{0.15}\right)^{1/2} \left(\frac{g_\mathrm{X}}{1.5}\right)^{-1} (m_\mathrm{X}/1.0\mathrm{keV})^{-4}, \tag{12.29}$$

the redshift of matter-radiation equality is given by

$$z_\mathrm{eq} = 3600 \left(\frac{\Omega_\mathrm{M} h_0^2}{0.15}\right) - 1, \tag{12.30}$$

and g_X and m_X are the effective number of degrees of freedom and the mass of the warm dark matter particle respectively. This fitting function has been found the fit the numerical results of Barkana et al. [2001] well.

12.6.9. Virial Density Contrast

The method used to compute the mean density contrast of virialized dark matter halos is selected via the `virialDensityContrastMethod` parameter.

Bryan & Norman (1998) Fitting Function

Selected with `virialDensityContrastMethod=Bryan-Norman1998` this method calculates virial density contrast using the fitting functions given by Bryan and Norman [1998]. As such, it is valid only for $\Omega_\Lambda = 0$ or $\Omega_\mathrm{M} + \Omega_\Lambda = 1$ cosmologies and will abort on other cosmologies.

Fixed

Selected with `virialDensityContrastMethod=fixed` this method uses a fixed virial density contrast of `[virialDensityConstrastFixed]`, defined relative to `criticalDensity` and `meanDensity` as specified by `[virialDensityConstrastFixedType]`.

Spherical Collapse (Matter + Cosmological Constant)

Selected with `virialDensityContrastMethod=sphericalTopHat` this method calculates virial density contrast using a spherical top-hat collapse model assuming a Universe which contains matter and a cosmological constant (see, for example, Percival 2005).

Kitayama & Suto (1996)

Selected with `virialDensityContrastMethod=Kitayama-Suto1996` this method calculates virial density contrast using the fitting formula of Kitayama and Suto [1996], and so is valid only in flat cosmological models (an error will be reported in non-flat models). Specifically,

$$\Delta_\mathrm{virial}(t) = 18\pi^2[1 + 0.4093 \left\{\frac{1}{\Omega_\mathrm{matter}(t)} - 1\right\}(t)^{0.9052}]. \tag{12.31}$$

Friends-of-Friends

Selected with `virialDensityContrastMethod=friendsOfFriends` this method computes the virial density contrast consistent with a given friends-of-friends algorithm linking length. According to Lacey and

Cole [1994], the friends-of-friends algorithm selects objects bounded by an isodensity contour of density contrast

$$\Delta_{\rm iso} = \frac{3}{2\pi b^3}, \tag{12.32}$$

where $b =$ `[virialDensityContrastFoFLinkingLength]` is the dimensionless linking length of the algorithm (i.e. the linking length in units of the mean interparticle spacing). The virial density contrast is then given by:

$$\Delta_{\rm vir} = \frac{\bar{\rho}_{\rm vir}}{\rho(r_{\rm vir})}\Delta_{\rm iso}, \tag{12.33}$$

where $\bar{\rho}_{\rm vir}$ is the mean density inside the virial radius and $\rho(r_{\rm vir})$ is the density at the virial radius. The ratio $\bar{\rho}_{\rm vir}/\rho(r_{\rm vir})$ is specified via the parameter `[virialDensityContrastFoFDensityRatio]`. Its default value of 4.688 is appropriate for an NFW halo of concentration $c = 6.88$ which is the concentration found by Prada et al. [2011] for halos with $\sigma = 1.686$ which is the approximate critical overdensity for collapse).

Percolation

Selected with `virialDensityContrastMethod=percolation` this method computes the virial density contrast consistent with a given friends-of-friends algorithm linking length using the percolation-theory-motivated calibration of More et al. [2011]. Specifically, the friends-of-friends algorithm is assumed to link together particles forming an isodensity surface of density $\rho = \bar{\rho} n_{\rm c}/b^3$, where $\bar{\rho}$ is the mean density of the universe, $n_{\rm c} = 0.652960$ is a critical density for percolation as given by More et al. [2011], and b is the linking length. Given this bounding density, the virial density contrast is found by requiring that the halo contain the required mass within such a bounding density, given the halo density profile.

12.6.10. Halo Bias

The dark matter halo linear bias method is selected via the `darkMatterHaloBiasMethod` parameter.

Press-Schechter

Selected with `darkMatterHaloBiasMethod=Press-Schechter` this method uses a bias consistent with the halo mass function of Press and Schechter [1974] (see [Mo and White, 1996]).

Sheth-Tormen

Selected with `darkMatterHaloBiasMethod=SMT` this method uses a bias consistent with the halo mass function of Sheth et al. [2001].

Tinker

Selected with `darkMatterHaloBiasMethod=Tinker2010` this method uses the functional form proposed by Tinker et al. [2010] to compute the halo bias. The bias is computed at the appropriate virial overdensity (see §12.6.9).

12.6.11. Halo Mass Function

The dark matter halo mass function (i.e. the number of halos per unit volume per unit mass interval) is selected via the `haloMassFunctionMethod` parameter.

Press-Schechter

Selected with `haloMassFunctionMethod=pressSchechter` this method uses the functional form proposed by Press and Schechter [1974] to compute the halo mass function. Specifically,

$$n(M,t) = 2\frac{\Omega_{\rm M}\rho_{\rm crit}}{M^2}\alpha\sigma^2(M)f[S(M,t)], \tag{12.34}$$

where $\alpha = \mathrm{d}\ln\sigma/\mathrm{d}\ln M$ and $f[S]$ is the excursion set barrier first crossing distribution for variance $S(M) = \sigma^2(M)$, computed using the selected `excursionSetFirstCrossingMethod` (see §16.4.1).

Sheth-Tormen

Selected with `haloMassFunctionMethod=shethTormen` this method uses the functional form proposed by Sheth et al. [2001] to compute the halo mass function.

Despali et al. (2015)

Selected with `haloMassFunctionMethod=despali2015` this method uses the functional form proposed by [Sheth et al., 2001, see §12.6.11] but with parameters a, p, and A set using eqn. (12) of Despali et al. [2015].

Tinker et al. (2008)

Selected with `haloMassFunctionMethod=tinker2008` this method uses the functional form proposed by Tinker et al. [2008] to compute the halo mass function. The mass function is computed at the appropriate virial overdensity (see §12.6.9).

Simple Systematic

Selected with `haloMassFunctionMethod=simpleSystematic` this method modifies another mass function (specified as a subparameter) as follows:

$$\frac{\mathrm{d}n}{\mathrm{d}M}(M) \rightarrow \frac{\mathrm{d}n}{\mathrm{d}M}(M)\left(1+\alpha+\beta\log_{10}\left[\frac{M}{10^{12}M_\odot}\right]\right) \tag{12.35}$$

where $\alpha =$`[alpha]`, and $\beta =$`[beta]`.

12.7. Cold Mode Infall Ratres

The method to be used for computing the rate of infall of gas from the cold mode is specified by the `coldModeInfallRateMethod` parameter.

12.7.1. Dynamical Time

The infall rate from the cold mode is given by

$$\dot{M}_{\rm infall,coldmode} = f_{\rm infall,coldmode}\frac{M_{\rm coldmode}}{\tau_{\rm dyn}}, \tag{12.36}$$

where $f_{\rm infall,coldmode} =$`[dynamicalRateFraction]`.

12.8. Conditional Mass Functions

The method to be used for computing the conditional mass function (for use in data modelling) is specified by the `conditionalMassFunctionMethod` parameter.

12.8.1. Behroozi et al. (2010)

Selected with `conditionalMassFunctionMethod=Behroozi2010`, this method uses the functional form given by Behroozi et al. (2010; see also Leauthaud et al. 2011). The mean number of central galaxies of stellar mass, $M_\star$, in halos of mass M_h is given by:

$$\log_{10}[f^{-1}_\mathrm{SHMR}(M_\star)] = \log_{10}(M_\mathrm{h}) = \log_{10}(M_1) + \beta \log_{10}\left(\frac{M_\star}{M_{\star,0}}\right) + \frac{(M_\star/M_{\star,0})^\delta}{1+(M_\star/M_{\star,0})^{-\gamma}} - \frac{1}{2}, \tag{12.37}$$

where

$$\langle n_\mathrm{cen}(M_\mathrm{h}|M^\rangle_\star\rangle = \frac{1}{2}\left[1-\mathrm{erf}\left(\frac{\log_{10}(M_\star)-\log_{10}[f_\mathrm{SHMR}(M_\mathrm{h})]}{\sqrt{2}\sigma_{\log M_\star}}\right)\right]. \tag{12.38}$$

The mean number of satellite galaxies of stellar mass, $M_\star$, in halos of mass M_h is given by:

$$\langle N_\mathrm{sat}(M_\mathrm{h}|M_\star)\rangle = \langle n_\mathrm{cen}(M_\mathrm{h}|M^\rangle_\star\rangle \left(\frac{f^{-1}_\mathrm{SHMR}(M_\star)}{M_\mathrm{sat}}\right)^{\alpha_\mathrm{sat}} \exp\left(-\frac{M_\mathrm{cut}}{f^{-1}_\mathrm{SHMR}(M_\star)}\right), \tag{12.39}$$

where

$$\frac{M_\mathrm{sat}}{10^{12}M_\odot} = B_\mathrm{sat}\left(\frac{f^{-1}_\mathrm{SHMR}(M_\star)}{10^{12}M_\odot}\right)^{\beta_\mathrm{sat}}, \tag{12.40}$$

and

$$\frac{M_\mathrm{cut}}{10^{12}M_\odot} = B_\mathrm{cut}\left(\frac{f^{-1}_\mathrm{SHMR}(M_\star)}{10^{12}M_\odot}\right)^{\beta_\mathrm{cut}}. \tag{12.41}$$

The number of centrals in a given halo is assumed to be Bernoulli distributed (0 or 1), while the number of satellites is assumed to be Poisson distributed with the above mean. The parameters of the distribution are controlled by the input parameters as listed in Table 12.1.

12.9. Cooling of Gas Inside Halos

The cooling of gas within dark matter halos is controlled by a number of different algorithms which will be decribed below.

12.9.1. Cooling Function

The cooling function of gas, $\Lambda(\rho, T, \mathbf{Z})$, is implemented by the algorithm(s) selected using the `coolingFunctionMethods` parameter. If more than one cooling function is specified, then the net cooling function is a sum over all of those selected.

Atomic Collisional Ionization Equilibrium Using Cloudy

Selected using `coolingFunctionMethods=atomic_CIE_Cloudy`, this method computes the cooling function using the Cloudy code and under the assumption of collisional ionization equilibrium with no molecular contribution. Abundances are Solar, except for zero metallicity calculations which use Cloudy's "primordial" metallicity. The helium abundance for non-zero metallicity is scaled between primordial and

Table 12.1.: The correspondance between parameters of the Behroozi et al. [2010] model for the conditional mass function and GALACTICUS input parameters.

Model parameter	Input parameter
$\alpha_{\rm sat}$	`conditionalMassFunctionBehrooziAlphaSatellite`
$\log_{10}(M_1/M_\odot)$	`conditionalMassFunctionBehrooziLog10M1`
$\log_{10}(M_{\star,0}/M_\odot)$	`conditionalMassFunctionBehrooziLog10Mstar0`
β	`conditionalMassFunctionBehrooziBeta`
δ	`conditionalMassFunctionBehrooziDelta`
γ	`conditionalMassFunctionBehrooziGamma`
$\sigma_{\log M_\star}$	`conditionalMassFunctionBehrooziSigmaLogMstar`
$B_{\rm cut}$	`conditionalMassFunctionBehrooziBCut`
$B_{\rm sat}$	`conditionalMassFunctionBehrooziBSatellite`
$\beta_{\rm cut}$	`conditionalMassFunctionBehrooziBetaCut`
$\beta_{\rm sat}$	`conditionalMassFunctionBehrooziBetaSatellite`

Solar values linearly with metallicity. The CLOUDY code will be downloaded and run to compute the cooling function as needed, which will then be stored for future use. As this process is slow, a precomputed table is provided with GALACTICUS. If metallicities outside the range tabulated in this file are required it will be regenerated with an appropriate range.

Collisional Ionization Eqiulibrium From File

Selected using `coolingFunctionMethods=CIE_from_file`, in this method the cooling function is read from a file specified by the `coolingFunctionFile` parameter. The format of this file is specified in §16.4.1. The cooling function is assumed to be computed under conditions of collisional ionization equilibrium and therefore to scale as ρ^2.

CMB Compton Cooling

Selected using `coolingFunctionMethods=CMB_Compton`, this method computes the cooling function due to Compton scattering off of CMB photons:

$$\Lambda = \frac{4\sigma_{\rm T} a k_{\rm B} n_{\rm e}}{m_{\rm e} c} T_{\rm CMB}^4 \left(T - T_{\rm CMB}\right), \tag{12.42}$$

where $\sigma_{\rm T}$ is the Thompson cross-section, a is the radiation constant, $k_{\rm B}$ is Boltzmann's constant, $n_{\rm e}$ is the number density of electrons, $m_{\rm e}$ is the electron mass, c is the speed of light, $T_{\rm CMB}$ is the CMB temperature at the current cosmic epoch and T is the temperature of the gas. The electron density is computed from the selected chemical state method (see §12.30).

Molecular Hydrogen (Galli-Palla)

Selected using `coolingFunctionMethods=molecularHydrogenGalliPalla`, this method computes the cooling function due to molecular hydrogen using the results of Galli and Palla [1998]. For the H–H_2 cooling function, the fitting functions from Galli and Palla [1998] are used. For the H_2^+–e^- and H–H_2^+ cooling functions fitting functions to the results plotted in Suchkov and Shchekinov [1978] are used:

$$\log_{10}\left(\frac{\Lambda(T)}{\rm erg\ s^{-1} cm^3}\right) = C_0 + C_1 \log_{10}\left(\frac{T}{\rm K}\right) + C_2 \left[\log_{10}\left(\frac{T}{\rm K}\right)\right]^2, \tag{12.43}$$

Table 12.2.: Coefficients of H_2^+ cooling functions as appearing in the fitting function, eq. 12.43.

	Coefficient		
Interaction	C_0	C_1	C_2
H_2^+–e^-	-33.33	5.565	-0.4675
H–H_2^+	-35.28	5.862	-0.5124

where the coefficients C_{0-2} are given in Table 12.2.

12.9.2. Cooling Rate

The algorithm used to compute the rate at which gas drops out of the hot halo due to cooling is selected with the `coolingRateMethod` parameter.

Cole et al. (2000)

Selected with `coolingRateMethod=Cole2000`, this method computes the cooling rate using the algorithm of Cole et al. [2000]. The cooling rate is given by

$$\dot{M}_{\rm cool} = \begin{cases} 4\pi r_{\rm infall}^2 \rho(r_{\rm infall}) \dot{r}_{\rm infall} & \text{if } r_{\rm infall} < r_{\rm hot,outer} \\ 0 & \text{if } r_{\rm infall} \geq r_{\rm hot,outer}, \end{cases} \tag{12.44}$$

where $\rho(r)$ is the density profile of the hot halo, and $r_{\rm infall}$ is the infall radius (see §12.9.6). The cooling rate is also set to zero in halos with virial velocities below `[coolingCutOffVelocity]` at redshifts below `[coolingCutOffRedshift]`.

Simple

Selected with `coolingRateMethod=simple`, this method computes the cooling rate using

$$\dot{M}_{\rm cool} = M_{\rm hot}/\tau_{\rm cool}, \tag{12.45}$$

where $\tau_{\rm cool}$ = `[coolingRateSimpleTimescale]`.

Simple Scaling

Selected with `coolingRateMethod=simpleScaling`, this method computes the cooling rate using

$$\dot{M}_{\rm cool} = M_{\rm hot}/\tau_{\rm cool}(M_{\rm halo}, z), \tag{12.46}$$

where

$$\tau_{\rm cool} = \tau_{\rm cool,0}(1+z)^{\beta_{\rm cool}} \exp\left(\left[\frac{M_{\rm halo}}{M_{\rm transition}}\right]^{\gamma_{\rm cool}}\right), \tag{12.47}$$

$\tau_{\rm cool,0}$ = `[coolingRateSimpleScalingTimescale]`, $\beta_{\rm cool}$ = `[coolingRateSimpleScalingTimescaleExponent]`, $M_{\rm transition}$ = `[coolingRateSimpleScalingTransitionMass]`, and $\gamma_{\rm cool}$ = `[coolingRateSimpleScalingCutoffExponent]`.

Velocity Maximum Scaling

Selected with `coolingRateMethod=velocityMaximumScaling`, this method computes the cooling rate using

$$\dot{M}_{\rm cool} = M_{\rm hot}/\tau_{\rm cool}(V_{\rm max,halo}, z), \tag{12.48}$$

where

$$\tau_{\rm cool} = \max\left[\tau_{\rm infall}\left(\frac{V_{\rm max}}{200{\rm km/s}}\right)^{-\gamma_{\rm infall}}(1+z)^{\alpha_{\rm infall}}\left(1+\exp\left[\frac{\log_{10}(V_{\rm max}/(1+z)^{\delta_{\rm infall}}\mathcal{V}_{\rm infall})]}{\Delta\log_{10}\mathcal{V}_{\rm infall}}\right]\right)^{\beta_{\rm infall}}, \tau_{\rm infall,min}\right], \tag{12.49}$$

with $\tau_{\rm infall}$ = `[coolingRateVelocityMaximumScalingTimescale]`, $\tau_{\rm infall,min}$ = `[coolingRateVelocityMaximumScalingTimes`
$\alpha_{\rm infall}$ = `[coolingRateVelocityMaximumScalingTimescaleExponent]`, $\beta_{\rm infall}$ = `[coolingRateVelocityMaximumScalingCut`
$\gamma_{\rm infall}$ = `[coolingRateVelocityMaximumScalingVelocityExponent]`, $\delta_{\rm infall}$ = `[]coolingRateVelocityMaximumScalingCut[`
$\mathcal{V}_{\rm infall}$ = `[coolingRateVelocityMaximumScalingCutOffVelocity]`, and $\Delta\log_{10}\mathcal{V}_{\rm infall}$ = `[coolingRateVelocityMaximumScal`

White & Frenk

Selected with `coolingRateMethod=White-Frenk1991`, this method computes the cooling rate using the expression given by White and Frenk [1991], namely

$$\dot{M}_{\rm cool} = \begin{cases} 4\pi r_{\rm infall}^2 \rho(r_{\rm infall})\dot{r}_{\rm infall} & \text{if } r_{\rm infall} < r_{\rm hot,outer} \\ M_{\rm hot}/\tau_{\rm halo,dynamical} & \text{if } r_{\rm infall} \geq r_{\rm hot,outer}, \end{cases} \tag{12.50}$$

where $r_{\rm infall}$ is the infall radius (see §12.9.6) in the hot halo and $\rho(r)$ is the density profile of the hot halo.

12.9.3. Cooling Rate Modifier

Algorithms that modify the rate of cooling of gas are specified via the `coolingRateModifierMethod` directive.

Cut-Off

This method sets the cooling rate to zero in halos with virial velocities below `[coolingCutOffVelocity]` at redshifts below/above `[coolingCutOffRedshift]` for `[coolingCutOffWhen]=after/before`. In other halos the cooling rate is not modified.

12.9.4. Cooling Radius

The algorithm used to compute the cooling radius is selected via the `coolingRadiusMethod` parameter.

Simple

Selcted with `coolingRadiusMethod=simple`, this method computes the cooling radius by seeking the radius at which the time available for cooling (see §12.9.9) equals the cooling time (see §12.9.8). The growth rate is determined consistently based on the slope of the density profile, the density dependence of the cooling function and the rate at which the time available for cooling is increasing. This method assumes that the cooling time is a monotonic function of radius.

Isothermal

Selected with `coolingRadiusMethod=isothermal`, this method computes the cooling radius by assuming an isothermal density profile, and a cooling rate proportional to density squared. This implies a cooling time:

$$t_{\rm cool} \equiv \frac{E}{\dot{E}} \propto \rho(r)^{-1}. \tag{12.51}$$

The cooling radius is then derived using

$$\rho(r_{\rm cool}) \propto t_{\rm available}^{-1} \tag{12.52}$$

which implies

$$r_{\rm cool} = r_{\rm virial} \left(\frac{t_{\rm available}}{t_{\rm cool,virial}} \right)^{1/2}, \tag{12.53}$$

where $t_{\rm cool,virial}$ is the cooling time at the virial radius.

12.9.5. Cooling: Freefall Radius

The algorithm used to compute the freefall radius for cooling is selected via the `freefallRadiusMethod` parameter.

Dark Matter Halo

Selected with `freefallRadiusMethod=darkMatterHalo`, this method assumes that the freefall radius corresponds to the radius at which the freefall time in the dark matter halo equals the time available for freefall (see §12.9.10).

12.9.6. Cooling: Infall Radius

The algorithm used to compute the infall radius for cooling is selected via the `infallRadiusMethod` parameter.

Cooling Radius

Selected with `infallRadiusMethod=coolingRadius`, this method assumes that the infall radius equals the cooling radius (see §12.9.4).

Cooling and Freefall Radii

Selected with `infallRadiusMethod=cooling and freefall`, this method assumes that the infall radius is equal to the smaller of the cooling and freefall radii (see §12.9.4 and §12.9.5).

Dark Matter Halo

Selected with `freefallRadiusMethod=darkMatterHalo`, this method computes the freefall radius by finding the radius in the dark matter halo profile from which a test particle could have free-fallen to zero radius (assuming it began at rest) in the time available for freefall (see §12.9.10).

12.9.7. Cooling Specific Angular Momentum

The algorithm used to compute the specific angular momentum of cooling gas is selected via the `coolingSpecificAngularMome` parameter.

Constant Rotation

Selected with `coolingSpecificAngularMomentumMethod=constantRotation`, this implementation assumes that the specific angular momentum of cooling gas is given either by

$$j_{\rm cool} = \langle j \rangle r_{\rm cool} A, \tag{12.54}$$

where $r_{\rm cool}$ is the cooling radius, A is the rotation normalization (see) and $\langle j \rangle$ is the mean specific angular momentum of the cooling gas, if `[coolingAngularMomentumUseInteriorMean]=false`, or by

$$j_{\rm cool} = \langle j \rangle I_3(r_{\rm cool})/I_2(r_{\rm cool}) A, \tag{12.55}$$

where $I_n(r)$ is the $n^{\rm th}$ radial moment of the hot gas density profile from 0 to r (this therefore gives the mean specific angular momentum interior to radius r), if `[coolingAngularMomentumUseInteriorMean]=true`.

If `[coolingMeanAngularMomentumFrom]=darkMatter` then $\langle j \rangle$ is the mean specific angular momentum of the dark matter halo, computed from its spin parameter, while if `[coolingMeanAngularMomentumFrom]=hotGas` then $\langle j \rangle$ is equal to the mean specific angular momentum of gas currently in the hot gas reservoir. If `[coolingRotationVelocityFrom]=darkMatter` then the rotation normalization A is computed using the dark matter density profile, while if `[coolingRotationVelocityFrom]=hotGas` it is computed using the density profile of the hot gas reservoir.

Mean

Selcted with `coolingSpecificAngularMomentumMethod=mean`, this assumes that the specific angular momentum of cooling gas is given by

$$j_{\rm cool} = J_{\rm hot}/M_{\rm hot}, \tag{12.56}$$

where $J_{\rm hot}$ and $M_{\rm hot}$ are the total angular momentum and mass of the hot halo respectively.

12.9.8. Cooling Time

The algorithm used to compute the time taken for gas to cool (i.e. the cooling time) is selected via the `coolingTimeMethod` parameter.

Simple

Selcted with `coolingTimeMethod=simple`, this method assumes that the cooling time is simply

$$t_{\rm cool} = \frac{N}{2} \frac{{\rm k_B} T n_{\rm tot}}{\Lambda}, \tag{12.57}$$

where N =`degreesOfFreedom` is the number of degrees of freedom in the cooling gas which has temperature T and total particle number density (including electrons) $n_{\rm tot}$ and Λ is the cooling function.

12.9.9. Time Available for Cooling

The method used to determine the time available for cooling (i.e. the time for which gas in a halo has been able to cool) is selected by the `coolingTimeAvailableMethod` parameter.

Halo Formation

Selected with `coolingTimeAvailableMethod=haloFormation`, this methods assumes that the time available for cooling is equal to

$$t_{\rm available} = t - t_{\rm form}, \tag{12.58}$$

where $t_{\rm form}$ is the time at which the halo formed (see §11.16).

White & Frenk (1991)

Selected with `coolingTimeAvailableMethod=White-Frenk1991`, this methods assumes that the time available for cooling is equal to

$$t_{\rm available} = \exp\left[f \ln t_{\rm Universe} + (1-f) \ln t_{\rm dynamical}\right], \tag{12.59}$$

where f =`coolingTimeAvailableAgeFactor` is an interpolating factor, $t_{\rm Universe}$ is the age of the Universe and $t_{\rm dynamical}$ is the dynamical time in the halo. The original White and Frenk [1991] algorithm corresponds to $f = 1$.

12.9.10. Time Available for Freefall During Cooling

The method used to determine the time available for freefall during cooling calculations (i.e. the time for which gas in a halo has been able to freefall) is selected by the `freefallTimeAvailableMethod` parameter.

Halo Formation

Selected with `freefallTimeAvailableMethod=haloFormation`, this methods assumes that the time available for freefall is equal to

$$t_{\rm available} = t - t_{\rm form}, \tag{12.60}$$

where $t_{\rm form}$ is the time at which the halo formed (see §11.16).

12.10. Cosmology

The method used to compute cosmological relations (e.g. expansion factor as a function of time) is selected by the `cosmologyMethod` parameter.

12.10.1. Matter + Cosmological Constant Universes

Selected with `cosmologyMethod=matter-lambda`, this method assumes a universe which contains only matter and a cosmological constant

12.11. Dark Matter Halos

Several algorithms are used to implement dark matter halos.

12.11.1. Mass Accretion History

The method used to compute mass accretion histories of dark matter halos is selected via the `darkMatterHaloMassAccretionH` parameter.

Wechsler et al. (2002)

Selected with `darkMatterHaloMassAccretionHistoryMethod=wechsler2002`, under this method the mass accretion history is given by [Wechsler et al., 2002]:

$$M(t) = M(t_0) \exp\left(-2a_{\rm c}\left[\frac{a(t_0)}{a(t)} - 1\right]\right), \tag{12.61}$$

where t_0 is some reference time and a_c is a characteristic expansion factor defined by Wechsler et al. [2002] to correspond to the formation time of the halo (using the formation time definition of Bullock et al. 2001).

Zhao et al. (2009)

Selected with `darkMatterHaloMassAccretionHistoryMethod=zhao2009`, under this method the algorithm given by Zhao et al. [2009] to compute mass accretion histories. In particular, Zhao et al. [2009] give a fitting function for the quantity $\mathrm{d}\ln\sigma(M)/\mathrm{d}\ln\delta_c(t)$ for the dimensionless growth rate in a mass accretion history at time t and halo mass M. This is converted to a dimensionful growth rate using

$$\frac{\mathrm{d}M}{\mathrm{d}t} = \left(\frac{\mathrm{d}\ln\sigma(M)}{\mathrm{d}\ln M}\right)^{-1} \left(\frac{\mathrm{d}\delta_c(t)}{\mathrm{d}t}\right) \left(\frac{M}{\delta_c(t)}\right) \left(\frac{\mathrm{d}\ln\sigma(M)}{\mathrm{d}\ln\delta_c(t)}\right). \tag{12.62}$$

This differential equation is then solved numerically to find the mass accretion history.

12.11.2. Density Profile

The method uses to compute density profiles of dark matter halos is selected via the `darkMatterProfileMethod` parameter.

Isothermal

Selected with `darkMatterProfileMethod=isothermal`, under this method the density profile is given by:

$$\rho_{\mathrm{darkmatter}}(r) \propto r^{-2}, \tag{12.63}$$

normalized such that the total mass of the node is enclosed with the virial radius.

NFW

Selected with `darkMatterProfileMethod=NFW`, under this method the NFW density profile [Navarro et al., 1997] is used

$$\rho_{\mathrm{darkmatter}}(r) \propto \left(\frac{r}{r_\mathrm{s}}\right)^{-1} \left[1 + \left(\frac{r}{r_\mathrm{s}}\right)\right]^{-2}, \tag{12.64}$$

normalized such that the total mass of the node is enclosed with the virial radius and with the scale length $r_\mathrm{s} = r_\mathrm{virial}/c$ where c is the halo concentration (see §12.11.3).

Einasto

Selected with `darkMatterProfileMethod=Einasto`, under this method the Einasto density profile (e.g. Cardone et al. 2005) is used

$$\rho_{\mathrm{darkmatter}}(r) = \rho_{-2} \exp\left(-\frac{2}{\alpha}\left[\left(\frac{r}{r_{-2}}\right)^{\alpha} - 1\right]\right), \tag{12.65}$$

normalized such that the total mass of the node is enclosed with the virial radius and with the characteristic length $r_{-2} = r_\mathrm{virial}/c$ where c is the halo concentration (see §12.11.3). The shape parameter, α, is set using the density profile shape method (see §12.11.4).

Burkert

Selected with `darkMatterProfileMethod=Burkert`, under this method the NFW density profile [Burkert, 1995] is used

$$\rho_{\rm darkmatter}(r) \propto \left(1+\frac{r}{r_{\rm s}}\right)^{-1}\left(1+[\frac{r}{r_{\rm s}}]^2\right)^{-1}, \tag{12.66}$$

normalized such that the total mass of the node is enclosed with the virial radius and with the scale length $r_{\rm s} = r_{\rm virial}/c$ where c is the halo concentration (see §12.11.3). The mass enclosed within radius r is given by

$$M(<r) = M_{\rm virial}\frac{2\log(1+R)+\log(1+R^2)-2\tan^{-1}(R)}{2\log(1+c)+\log(1+c^2)-2\tan^{-1}(c)}, \tag{12.67}$$

where $R = r/r_{\rm s}$. The associated gravitational potential is

$$\Phi(r) = -{\rm G}\left(1+\frac{1}{R}\right)\frac{2\tan^{-1}(R)-2\log(1+R)+\log(1+R^2)}{-2\tan^{-1}(c)+2\log(1+c)+\log(1+c^2)}. \tag{12.68}$$

The peak of the rotation curve occurs at $R = 3.2446257246042642$ (found by numerical solution), and the Fourier transform of the profile, $F(k) = \int_0^c 4\pi r^2 \exp(-ikr)\rho(r){\rm d}r/kr$ (needed in calculations of clustering using the halo model) is given by

$$\begin{aligned} F(k) \quad = \quad & \{2\exp(-ik){\rm C_i}(k) - 2\exp(-ik){\rm C_i}(k[1+c]) + (1+i)\,[-i\exp(k)\pi - \exp(k){\rm E_i}(-k) \\ & + i\exp(-k){\rm E_i}(k) + \exp(k){\rm E_i}(i[i+c]k) - i\exp(-k){\rm E_i}(k[1+ic]) + (1+i)\exp(-ik){\rm S_i}(k) \\ & -(1+i)\exp(-ik){\rm S_i}(k[1+c])]\} \,/\, \left[k\left\{-2\tan^{-1}(c)+2\log(1+c)+\log(1+c^2)\right\}\right]. \end{aligned} \tag{12.69}$$

Tidally-heated

Selected with `darkMatterProfileMethod=tidallyHeated`, this method assumes that dark matter halos start out with a density profile defined by another `darkMatterProfileMethod` (specified via `[darkMatterProfileTidallyHea`
For subhalos, this profile is modified by tidal heating, under the assumption that the energy of a shell of mass before and after heating are related by

$$\frac{{\rm G}M'(r')}{r'} = \frac{{\rm G}M(r)}{r} + Qr^2, \tag{12.70}$$

where $M(r)$ is the mass enclosed within a radius r, and Q represents a normalized tidal heating (see §11.10.4 for example). Primes indicate values after heating, while unprimed variables indicate quantities prior to heating. With the assumption of no shell crossing, $M'(r') = M(r)$ and this equation can be solved for r given r'.

Not all methods are implemented for this profile. If `[darkMatterProfileTidallyHeatedUnimplementedIsFatal]=true` then attempts to call these methods in heated profiles aborts, otherwise, a warning is issued and the result for the unheated profile is used instead.

12.11.3. Dark Matter Halo Profile Concentration

The method uses to compute the concentrations of dark matter profiles is selected via the `darkMatterProfileConcentrationM` parameter.

Navarro, Frenk & White (1996)

Selected with `darkMatterProfileConcentrationMethod=NFW1996`, under this method the concentration is computed using the algorithm from Navarro et al. [1996]. In this algoritm, for a given halo of mass M at time t_0, a formation time is defined as the epoch at which there is a 50% probability (according to extended Press-Schechter theory) for a progenitor halo to have a mass greater than fM, where $f =$`[nfw96ConcentrationF]` is a parameter of the algorithm. This implies formation when the critical overdensity for collapse is

$$\delta_{\rm crit}(t_{\rm form}) = \left[2\nu_{1/2}^2 \left\{\sigma(fM)^2 2 - \sigma(M)^2\right\}\right]^{1/2} + \delta_{\rm crit}(t_0), \tag{12.71}$$

where $\nu_{1/2} = [{\rm erfc}^{-1}(1/2)]^{1/2}$. Navarro et al. [1996] then assume an overdensity at collapse of

$$\Delta(t_{\rm form}) = C\left[\frac{a(t_0)}{a(t_{\rm form})}\right]^3 \tag{12.72}$$

where $C =$`[nfw96ConcentrationC]` is a parameter of the algorithm. The concentration is then determined by solving

$$\frac{\Delta(t_{\rm form})}{\Delta_{\rm virial}(t_0)} = \frac{c^3}{3[\ln(1+c) - c/(1+c)]}. \tag{12.73}$$

Gao (2008)

Selected with `darkMatterProfileConcentrationMethod=gao2008`, under this method the concentration is computed using a fitting function from Gao et al. [2008]:

$$\log_{10} c = A \log_{10} M_{\rm halo} + B. \tag{12.74}$$

The parameters are a functon of expansion factor, a. We use the following fits to the Gao et al. [2008] results:

$$A = -0.140 \exp\left[-\left(\{\log_{10} a + 0.05\}/0.35\right)^2\right], \tag{12.75}$$

$$B = 2.646 \exp\left[-\left(\log_{10} a/0.50\right)^2\right]. \tag{12.76}$$

Zhao (2009)

Selected with `darkMatterProfileConcentrationMethod=zhao2009`, under this method the concentration is computed using a fitting function from Zhao et al. [2009]:

$$c = 4\left(1 + \left[\frac{t}{3.75 t_{\rm form}}\right]^{8.4}\right)^{1/8}, \tag{12.77}$$

where t is the time for the halo and $t_{\rm form}$ is a formation time defined by Zhao et al. [2009] as the time at which the main branch progenitor of the halo had a mass equal to 0.04 of the current halo mass. This formation time is computed directly from the merger tree branch associated with each halo. If the no branch exists or does not extend to the formation time then the formation time is computed by extrapolating the mass of the earliest resolved main branch progenitor to earlier times using the selected mass accretion history method (see §16.4.1).

Muñoz-Cuartas (2011)

Selected with `darkMatterProfileConcentrationMethod=munozCuartas2011`, under this method the concentration is computed using a fitting function from Muñoz-Cuartas et al. [2011]:

$$\log_{10} c = a \log_{10} \left(\frac{M_{\rm halo}}{h^{-1} M_\odot} \right) + b. \tag{12.78}$$

The parameters are a functon of redshift, z, given by

$$a = wz - m, \tag{12.79}$$

$$b = \frac{\alpha}{(z+\gamma)} + \frac{\beta}{(z+\gamma)^2}, \tag{12.80}$$

where $w = 0.029$, $m = 0.097$, $\alpha = -110.001$, $\beta = 2469.720$, $\gamma = 16.885$.

Prada et al. (2011)

Selected with `darkMatterProfileConcentrationMethod=prada2011`, under this method the concentration is computed using a fitting function from Prada et al. [2011]:

$$c(M,t) = B_0(x) \mathcal{C}(\sigma'), \tag{12.81}$$

where

$$\sigma'(M,t) = B_1(x)\sigma(M,t), \tag{12.82}$$

$$B_0(x) = c_{\rm min}(x)/c_{\rm min}(1.393), \tag{12.83}$$

$$B_1(x) = \sigma^{-1}_{\rm min}(x)/\sigma^{-1}_{\rm min}(1.393), \tag{12.84}$$

$$c_{\rm min}(x) = c_0 + (c_1 - c_0)[\tan^{-1}\{\alpha(x - x_0)\}/\Pi + 1/2], \tag{12.85}$$

$$\sigma^{-1}_{\rm min}(x) = \sigma_0^{-1} + (\sigma_1^{-1} - \sigma_0^{-1})[\tan^{-1}\{\beta(x - x_1)\}/\Pi + 1/2], \tag{12.86}$$

$$\mathcal{C}(\sigma') = A[(\sigma')/b)^c + 1] \exp(d/\sigma'^2), \tag{12.87}$$

$$x = (\Omega_\Lambda/\Omega_{\rm M})^{1/3} a(t), \tag{12.88}$$

with the following parameters (default values taken from Prada et al. [2011] given in []): $A =$ `[prada2011ConcentrationA]` $=$ 2.881, $b =$ `[prada2011ConcentrationB]` $=$ 1.257, $c =$ `[prada2011ConcentrationC]` $=$ 1.022, $d =$ `[prada2011ConcentrationD]` 0.060, $c_0 =$ `[prada2011ConcentrationC0]` $=$ 3.681, $c_1 =$ `[prada2011ConcentrationC1]` $=$ 5.033, $x_0 =$ `[prada2011Concentrat` 0.424, $x_1 =$ `[prada2011ConcentrationX1]` $=$ 0.526, $\sigma_0^{-1} =$ `[prada2011ConcentrationInverseSigma0]` $=$ 1.047, $\sigma_1^{-1} =$ `[prada2011ConcentrationInverseSigma1]` $=$ 1.646, $\alpha =$ `[prada2011ConcentrationAlpha]` $=$ 6.948, and $\beta =$ `[prada2011ConcentrationBeta]` $=$ 7.386.

Dutton & Macciò (2014)

Selected with `darkMatterProfileConcentrationMethod=duttonMaccio2014`, under this method the concentration is computed using a fitting function from Dutton and Macciò [2014]:

$$\log_{10} c = A + B \log_{10} M_{\rm halo}. \tag{12.89}$$

The parameters are a functon of redshift, z. We use the following fit suggested by Dutton and Macciò [2014] results:

$$A = A_1 + (A_2 - A_1) \exp[A_3 z^{A_4}]$$

$$B = B_1 + B_2 z. \tag{12.90}$$

The coefficients are chosen from one of the three sets given by Dutton and Macciò [2014], controlled via the `[duttonMaccio2014FitType]` parameter, as described in Table 12.3.

Fit type	Profile	$\Delta_{\rm vir}$	A_1	A_2	A_3	A_4	B_1	B_2
`nfwVirial`	NFW	Top-hat	+0.537	+1.025	−0.718	+1.080	−0.097	+0.024
`nfw200`	NFW	200	+0.520	+0.905	−0.617	+1.210	−0.101	+0.026
`einasto200`	Einasto	200	+0.459	+0.977	−0.490	+1.303	−0.130	+0.029

Table 12.3.: Coefficients appearing in the dark matter halo profile concentration fitting functions of Dutton and Macciò [2014]. The "fit type" is specified by the `[duttonMaccio2014FitType]` parameter.

Diemer & Kravtsov (2014)

Selected with `darkMatterProfileConcentrationMethod=diemerKravtsov2014`, under this method the concentration is computed using a fitting function from Diemer and Kravtsov [2014]:

$$c = \frac{c_{\rm min}}{2}\left[\left(\frac{\nu}{\nu_{\rm min}}\right)^{-\alpha} + \left(\frac{\nu}{\nu_{\rm min}}\right)^{\beta}\right], \tag{12.91}$$

where $c_{\rm min} = \phi_0 + \phi_1 n$, $\nu_{\rm min} = \eta_0 + \eta_1 n$, n is the logarithmic slope of the linear power spectrum at wavenumber $k = \kappa 2\pi/R$, R is the comoving Lagrangian radius of the halo, $R = [3M/4\pi\rho_{\rm M}(z=0)]^{1/3}$, and $\nu = \delta_{\rm crit}(t)/\sigma(M)$ is the peak height parameter. The numerical parameters $(\kappa, \phi_0, \phi_1, \eta_0, \eta_1, \alpha, \beta)$ are set by the parameters `[darkMatterProfileConcentrationDiemerKravtsov2014Kappa]`, `[darkMatterProfileConcentrationD`
`[darkMatterProfileConcentrationDiemerKravtsov2014Phi1]`, `[darkMatterProfileConcentrationDiemerKravtsov201`
`[darkMatterProfileConcentrationDiemerKravtsov2014Eta1]`, `[darkMatterProfileConcentrationDiemerKravtsov201`
`[darkMatterProfileConcentrationDiemerKravtsov2014Beta]`, respectively, and default to the values given in Table 3 of Diemer and Kravtsov [2014] for the median relation, namely $(0.69, 6.58, 1.37, 6.82, 1.42, 1.12, 1.69)$.

Schneider (2015)

Selected with `darkMatterProfileConcentrationMethod=schneider2015`, under this method the concentration using the algorithm of Schneider [2015]. Specifically, a reference model for concentrations in defined in a specific cosmological model. The concentration for a halo of given mass, M, and redshift, z_0, is then found by finding the redshift of collapse, $z_{\rm c}$ for the halo by solving:

$$\delta_{\rm c}(z_{\rm c}) = \left(\frac{\pi}{2}\left[\sigma^2(fM) - \sigma^2(M)\right]\right)^{1/2} + \delta_{\rm c})(z_0), \tag{12.92}$$

where $\delta_{\rm c}(z)$ is the critical overdensity for collapse at redshift z, and f is the fraction of a halo's mass assembled at formation time (given by the `[massFractionFormation]` parameter. From this, the mass of a halo in the reference model with the same redshift of collapse is found, and the reference model is used to compute the concentration of a halo of that mass.

WDM

Selected with `darkMatterProfileConcentrationMethod=WDM`, under this method the concentration is computed by applying the correction factor of Schneider et al. [2012]:

$$c_{\rm WDM} = c_{\rm CDM}\left[1 + \gamma_1\left(\frac{M_{1/2}}{M_{\rm halo}}\right)^{\gamma_2}\right]^{-1}, \tag{12.93}$$

where $\gamma_1 = 15$, $\gamma_2 = 0.3$, $M_{1/2}$ is the mass corresponding to the wavenumber at which the WDM transfer function is suppressed below the CDM transfer function by a factor of 2, and $M_{\rm halo}$ is the mass of the dark matter halo, to a CDM concentration algorithm as specified by `[darkMatterProfileConcentrationCDMMethod]`.

12.11.4. Density Profile Shape

The method used to compute any shape parameter of dark matter profiles is selected via the `darkMatterShapeMethod` parameter.

Gao (2008)

Selected with `darkMatterShapeMethod=Gao2008`, under this method the shape parameter for Einasto density profiles is computed using a fitting function from Gao et al. [2008]:

$$\alpha = \begin{cases} 0.155 + 0.0095\nu^2 & \text{if } \nu < 3.907 \\ 0.3 & \text{if } \nu \geq 3.907, \end{cases} \tag{12.94}$$

where $\nu = \delta_c(t)/\sigma(M)$ is the peak height of the halo. The truncation at $\alpha = 0.3$ is included since Gao et al. [2008]'s fits do not probe this region and extremely large values of α are numerically troublesome.

12.11.5. Mass Loss Rates

The method used to compute the rate of mass loss from dark matter (sub)halos is selected via the `darkMatterHaloMassLossRateMethod` parameter.

Null

Selected with `darkMatterHaloMassLossRateMethod=null`, this method assumes a zero rate of mass loss from dark matter halos.

van den Bosch et al. (2005)

Selected with `darkMatterHaloMassLossRateMethod=vanDenBosch2005`, this method uses the algorithm of van den Bosch et al. [2005] to compute the rate of mass loss. Specifically:

$$\dot{M}_{\rm node,bound} = -\frac{M_{\rm node,bound}}{\tau} \left(M_{\rm node,bound}/M_{\rm node,parent}\right)^{\zeta}, \tag{12.95}$$

where $M_{\rm node,parent}$ is the mass of the parent node in which the halo lives and

$$\tau = \tau_0 \left(\frac{\Delta_{\rm vir}(t)}{\Delta(t_0)}\right)^{-1/2} a^{3/2}, \tag{12.96}$$

where $\Delta_{\rm vir}(t)$ is the virial overdensity of halos at time t and a is the expansion factor. The fitting parameters, τ_0 and ζ have values of 0.13 Gyr and 0.36 respectively as determined by van den Bosch et al. [2005]. Note that van den Bosch et al. [2005] write this expression in a slightly different form since their $\Delta_{\rm vir}$ is defined relative to the critical density rather than the mean density as it is in Galacticus. In both cases, the timescale τ simply scales as $\langle\rho_{\rm vir}\rangle^{-1/2}$ where $\langle\rho_{\rm vir}\rangle$ is the mean virial overdensity of halos.

12.11.6. Mass Sampling Density Function

The method used to compute the halo mass density function is selected via the `haloMassFunctionSamplingMethod` parameter.

Power Law

Selected with `haloMassFunctionSamplingMethod=powerLaw`, under this method the sampling density function is given by

$$\gamma(M) = \log_{10}(M/M_{\rm minimum})^{-\alpha/(1+\alpha)}, \tag{12.97}$$

The resulting distribution of halo masses is such that the mass of the $i^{\rm th}$ halo is

$$M_{\rm halo,i} = \exp\left[\ln(M_{\rm halo,min}) + \ln\left(M_{\rm halo,max}/M_{\rm halo,min}\right) x_i^{1+\alpha}\right]. \tag{12.98}$$

Here, x_i is a number between 0 and 1 and α =`mergerTreeBuildTreesHaloMassExponent` is an input parameter that controls the relative number of low and high mass tree produced.

Halo Mass Function

Selected with `haloMassFunctionSamplingMethod=haloMassFunction`, this method sets the sampling density function equal to the halo mass function,

$$\gamma(M) = {\rm minmax}(\phi_{\rm min}, \phi_{\rm max}, {\rm d}n(M)/{\rm d}\log M[1 + p_1 \log_{10}(M/10^{13}M_\odot) + p_2 \log_{10}^2(M/10^{13}M_\odot)), \tag{12.99}$$

where $\phi_{\rm min}$ =`[haloMassFunctionSamplingAbundanceMinimum]`, $\phi_{\rm max}$ =`[haloMassFunctionSamplingAbundanceMaximum]`, p_1 =`[haloMassFunctionSamplingModifier1]`, p_2 =`[haloMassFunctionSamplingModifier2]`, and

$${\rm minmax}(a,b,x) = \begin{cases} a & \text{if } x < a \\ x & \text{if } a \le x \le b \\ b & \text{if } x > b, \end{cases} \tag{12.100}$$

resulting in a sample of halos representative of a volume of space.

Stellar Mass Function

Selected with `haloMassFunctionSamplingMethod=stellarMassFunction`, in this case the sampling density is chosen to give optimally minimal errors on the model stellar mass function (see §9.4.1 for full details). This calculation requires the observational errors on the stellar mass function to be known. A simple model of the form

$$\sigma^2(M) = \left[\phi_0 \left(\frac{M}{M_*}\right)^\alpha \exp\left(-\left[\frac{M}{M_*}\right]^\beta\right)\right]^2 + \sigma_0^2 \tag{12.101}$$

is used to model the error, $\sigma(M)$, on the observed stellar mass function as a function of stellar mass, M, where ϕ_0 =`[haloMassFunctionSamplingStellarMassFunctionErrorPhi0]`,M_* =`[haloMassFunctionSamplingStellarMas`
and σ_0 =`[haloMassFunctionSamplingStellarMassFunctionErrorConstant]`.

12.11.7. Spin Parameter Distribution

The method used to compute the distribution of dark matter halo spin parameters is selected via the `haloSpinDistributionMethod` parameter.

Lognormal

Selected with `haloSpinDistributionMethod=lognormal`, under this method the spin is drawn from a lognormal distribution with median `[lognormalSpinDistributionMedian]` and width `[lognormalSpinDistributionSigma]`

Bett et al. (2007)

Selected with `haloSpinDistributionMethod=Bett2007`, under this method the spin is drawn from the distribution found by Bett et al. [2007]. The λ_0 and α parameter of Bett et al.'s distribution are set by the `[spinDistributionBett2007Lambda0]` and `[spinDistributionBett2007Alpha]` input parameters.

Delta Function

Selected with `haloSpinDistributionMethod=deltaFunction`, under this method the spin is drawn from a delta function distribution, $P(\lambda) = \delta(\lambda - \lambda_0)$, where $\lambda_0 =$`[deltaFunctionSpinDistributionSpin]`, i.e. a fixed value of spin equal to λ_0 is returned.

12.12. Disk Stability/Bar Formation

The method uses to compute the bar instability timescale for galactic disks is selected via the `barInstabilityMethod` parameter.

12.12.1. Null

Selected with `barInstabilityMethod=null`, this method assumes no instability and so returns an infinite timescale, and no external driving torque.

12.12.2. Efstathiou, Lake & Negroponte

Selected with `barInstabilityMethod=ELN`, this method uses the stability criterion of Efstathiou et al. [1982] to estimate when disks are unstable to bar formation:

$$\epsilon \left(\equiv \frac{V_{\rm peak}}{\sqrt{{\rm G}M_{\rm disk}/r_{\rm disk}}} \right) < \epsilon_{\rm c}, \tag{12.102}$$

for stability, where $V_{\rm peak}$ is the peak velocity in the rotation curve (computed here assuming an isolated exponential disk), $M_{\rm disk}$ is the mass of the disk and $r_{\rm disk}$ is its scale length (assuming an exponential disk). The value of $\epsilon_{\rm c}$ is linearly interpolated in the disk gas fraction between values for purely gaseous and stellar disks as specified by `stabilityThresholdStellar` and `stabilityThresholdGaseous` respectively. For disks which are judged to be unstable, the timescale for bar formation is estimated to be

$$t_{\rm bar} = t_{\rm disk} \left(\frac{\epsilon_{\rm c} - \epsilon_{\rm iso}}{\epsilon_{\rm c} - \epsilon} \right)^2, \tag{12.103}$$

where $\epsilon_{\rm iso}$ is the value of ϵ for an isolated disk and $t_{\rm disk}$ is the disk dynamical time, defined as r/V, at one scale length. This form gives an infinite timescale at the stability threshold, reducing to a dynamical time for highly unstable disks, while also ensuring that the slope of $t_{\rm bar}$ is continuous at the instability threshold. This method returns zero external driving torque.

12.12.3. Efstathiou, Lake & Negroponte + Tidal Forces

Selected with `barInstabilityMethod=ELN+tidal`, this method uses the stability criterion of Efstathiou et al. [1982] to estimate when disks are unstable to bar formation, but includes an additional term due to external tidal forces:

$$\epsilon \left(\equiv \frac{V_{\rm peak}}{\sqrt{{\rm G}M_{\rm disk}/r_{\rm disk}} + \max(\mathcal{T}, 0)} \right) < \epsilon_{\rm c}, \tag{12.104}$$

for stability, where $V_{\rm peak}$ is the peak velocity in the rotation curve (computed here assuming an isolated exponential disk), $M_{\rm disk}$ is the mass of the disk, $r_{\rm disk}$ is its scale length (assuming an exponential disk), $\mathcal{T} = \mathcal{F} r_{\rm disk}^2$ is the external driving specific torque, and $\mathcal{F}$ is the external tidal field (evaluated using the selected method; see §12.42). The value of $\epsilon_{\rm c}$ is linearly interpolated in the disk gas fraction between values for purely gaseous and stellar disks as specified by `stabilityThresholdStellar` and `stabilityThresholdGaseous` respectively. For disks which are judged to be unstable, the timescale for bar formation is estimated to be

$$t_{\rm bar} = t_{\rm disk} \frac{\epsilon_{\rm c} - \epsilon_{\rm iso}}{\epsilon_{\rm c} - \epsilon}, \tag{12.105}$$

where $\epsilon_{\rm iso}$ is the value of ϵ for an isolated disk and $t_{\rm disk}$ is the disk dynamical time, defined as r/V, at one scale length. This form gives an infinite timescale at the stability threshold, reducing to a dynamical time for highly unstable disks.

12.13. Excursion Set Barrier

The functional form of the excursion set barrier is selected via the `excursionSetBarrierMethod` parameter.

12.13.1. Linear Barrier

Selected with `excursionSetBarrierMethod=linear` this method assumes a barrier:

$$B(S) = B_0 + B_1 S, \tag{12.106}$$

where $B_0 =$`[excursionSetBarrierConstantCoefficient]`, and $B_0 =$`[excursionSetBarrierLinearCoefficient]`.

12.13.2. Quadratic Barrier

Selected with `excursionSetBarrierMethod=quadratic` this method assumes a barrier:

$$B(S) = B_0 + B_1 S + B_2 S^2, \tag{12.107}$$

where $B_0 =$`[excursionSetBarrierConstantCoefficient]`, $B_0 =$`[excursionSetBarrierLinearCoefficient]`, and $B_2 =$`[excursionSetBarrierQuadraticCoefficient]`.

12.13.3. Critical Overdensity Barrier

Selected with `excursionSetBarrierMethod=criticalOverdensity` this method assumes a barrier equal to the critical linear theory overdensity for halo collpase (see §12.6.7).

12.14. Excursion Set Barrier First Crossing Distribution

The algorithm to be used when solving the excursion set barrier first crossing distribution problem is selected via the `excursionSetFirstCrossingMethod` parameter.

12.14.1. Linear Barrier

Selected with `excursionSetFirstCrossingMethod=linearBarrier` this method assumes the solution for a linear barrier. Specifically, the first crossing distribution is

$$f(S,t) = B(0,t)\exp(-B(S,t)^2/2S)/S/\sqrt{2piS}, \tag{12.108}$$

where $B(S,t)$ is the (assumed-to-be-linear-in-S) barrier at time t and variance S. The first crossing rate is computed using a finite difference approximation between two closely-spaced times. The non-crossing rate is zero.

12.14.2. Farahi

Selected with `excursionSetFirstCrossingMethod=Farahi` this method solves the barrier first crossing problem using the method of Farahi (see Benson et al. 2012), which proceeds by finding the solution to the integral equation:

$$1 = \int_0^S f(S')\mathrm{d}S' + \int_{-\infty}^{B(S)} P(\delta,S)\mathrm{d}\delta, \tag{12.109}$$

where $P(\delta,S)\mathrm{d}\delta$ is the probability for a trajectory to lie between δ and $\delta+\mathrm{d}\delta$ at variance S. In the absence of a barrier, $P(\delta,S)$ would be equal to $P_0(\delta,S)$ which is simply a Gaussian distribution with variance S:

$$P_0(\delta,S) = \frac{1}{\sqrt{2\pi S}}\exp\left(-\frac{\delta^2}{2S}\right). \tag{12.110}$$

Since the barrier absorbs any random walks which cross is at smaller S, the actual $P(\delta,S)$ must therefore be given by:

$$P(\delta,S) = P_0(\delta,S) - \int_0^S f(S')P_0[\delta - B(S'), S-S']\mathrm{d}S'. \tag{12.111}$$

In the second term on the right hand side of eqn. (12.111) represents the $P_0[\delta - B(S'), S-S']$ term represents the distribution of random trajectories orginating from the point $(S,B(S))$. The integral therefore gives the fraction of trajectories which crossed the barrier at $S < S'$ and which can now be found at (S,δ).

Using this result, we can rewrite eqn. (12.109):

$$1 = \int_0^S f(S')\mathrm{d}S' + \int_{-\infty}^{B(S)} \left[P_0(\delta,S) - \int_0^S f(S')P_0(\delta - B(S'), S-S')\mathrm{d}S')\right]\mathrm{d}\delta, \tag{12.112}$$

in general and, for the Gaussian distribution of eqn. (12.110):

$$1 = \int_0^S f(S')\mathrm{d}S' + \int_{-\infty}^{B(S)} \left[\frac{1}{\sqrt{2\pi S}}\exp\left(-\frac{\delta^2}{2S}\right) - \int_0^S f(S')\frac{1}{\sqrt{2\pi(S-S')}}\exp\left(-\frac{[\delta - B(S')]^2}{2(S-S')}\right)\mathrm{d}S'\right]\mathrm{d}\delta. \tag{12.113}$$

The integral over $\mathrm{d}\delta$ can be carried out analytically to give:

$$1 = \int_0^S f(S')\mathrm{d}S' + \mathrm{erf}\left[\frac{B(S)}{\sqrt{2S}}\right] - \int_0^S f(S')\mathrm{erf}\left[\frac{B(S)-B(S')}{\sqrt{2(S-S')}}\right]\mathrm{d}S''. \tag{12.114}$$

We now discretize eqn. (12.114). Specifically, we divide the S space into N intervals defined by the points:

$$S_i = \begin{cases} 0 & \text{if } i = 0 \\ \sum_0^{i-1}\Delta S_i & \text{if } i > 1. \end{cases} \tag{12.115}$$

Note that $f(0) = 0$ by definition, so $f(S_0) = 0$ always. We choose $\Delta S_i = S_{\max}/N$ (i.e. uniform spacing in S) when computing first crossing distributions, and $\Delta S_i \propto S_i$ (i.e. uniform spacing in $\log(S)$) when computing first crossing rates.

Discretizing the integrals in eqn. (12.114) gives:

$$\int_0^{S_j} f(S')\mathrm{d}S' = \sum_{i=0}^{j-1} \frac{f(S_i) + f(S_{i+1})}{2} \Delta S_i \tag{12.116}$$

and:

$$\int_0^{S_j} f(S')\mathrm{erf}\left[\frac{B(S) - B(S')}{\sqrt{2(S - S')}}\right] \mathrm{d}S' = \sum_{i=0}^{j-1} \frac{1}{2}\left(f(S_i)\mathrm{erf}\left[\frac{B(S_j) - B(S_i)}{\sqrt{2(S_j - S_i)}}\right] + f(S_{i+1})\mathrm{erf}\left[\frac{B(S_j) - B(S_{i+1})}{\sqrt{2(S_j - S_{i+1})}}\right]\right)\Delta S_i. \tag{12.117}$$

We can now rewrite eqn. (12.114) in discretized form:

$$1 = \sum_{i=0}^{j-1} \frac{f(S_i) + f(S_{i+1})}{2}\Delta S_i + \mathrm{erf}\left[\frac{B(S_j)}{\sqrt{2S_j}}\right] - \frac{1}{2}\sum_{i=0}^{j-1}\left(f(S_i)\mathrm{erf}\left[\frac{B(S_j) - B(S_i)}{\sqrt{2(S_j - S_i)}}\right] + f(S_{i+1})\mathrm{erf}\left[\frac{B(S_j) - B(S_{i+1})}{\sqrt{2(S_j - S_{i+1})}}\right]\right)\Delta S_i. \tag{12.118}$$

Solving eqn. (12.118) for $f(S_j)$:

$$\begin{aligned}\left(\frac{1}{2} - \frac{1}{2}\mathrm{erf}\left[\frac{B(S_j) - B(S_j)}{\sqrt{2(S_j - S_j)}}\right]\right)\Delta S_{j-1} f(S_j) \quad = \quad & 1 - \sum_{i=0}^{j-2} \frac{f(S_i) + f(S_{i+1})}{2}\Delta S_i - \frac{f(S_{j-1})}{2}\Delta S_{j-1} - \mathrm{erf}\left\{\frac{B(S_j)}{\sqrt{2S_j}}\right\} \\ & + \frac{1}{2}\sum_{i=0}^{j-2}\left(f(S_i)\mathrm{erf}\left\{\frac{[B(S_j) - B(S_i)]}{\sqrt{2(S_j - S_i)}}\right\} + f(S_{i+1})\mathrm{erf}\left\{\frac{[B(S_j) - B(S_{i+1})]}{\sqrt{2(S_j - S_{i+1})}}\right\}\right) \\ & + \frac{1}{2}f(S_{j-1})\mathrm{erf}\left\{\frac{[B(S_j) - B(S_{j-1})]}{\sqrt{2(S_j - S_{j-1})}}\right\}\Delta S_{j-1}. \end{aligned} \tag{12}$$

For all barriers that we consider:

$$\mathrm{erf}\left[\frac{B(S_j) - B(S_j)}{\sqrt{2(S_j - S_j)}}\right] = 0. \tag{12.120}$$

We can then simplify eqn. (12.119):

$$\begin{aligned} f(S_j) \quad = \quad & \frac{2}{\Delta S_{j-1}}\left[1 - \sum_{i=0}^{j-2} \frac{f(S_i) + f(S_{i+1})}{2}\Delta S_i - \frac{f(S_{j-1})}{2}\Delta S_{j-1} - \mathrm{erf}\left\{\frac{B(S_j)}{\sqrt{2S_j}}\right\}\right. \\ & + \frac{1}{2}\sum_{i=0}^{j-2}\left(f(S_i)\mathrm{erf}\left\{\frac{[B(S_j) - B(S_i)]}{\sqrt{2(S_j - S_i)}}\right\} + f(S_{i+1})\mathrm{erf}\left\{\frac{[B(S_j) - B(S_{i+1})]}{\sqrt{2(S_j - S_{i+1})}}\right\}\right)\Delta S_i \\ & \left. + \frac{1}{2}f(S_{j-1})\mathrm{erf}\left\{\frac{[B(S_j) - B(S_{j-1})]}{\sqrt{2(S_j - S_{j-1})}}\right\}\Delta S_{j-1}\right]. \end{aligned} \tag{12.121}$$

Consolidating terms in the summations:

$$f(S_j) = \frac{2}{\Delta S_{j-1}}\left[1 - \mathrm{erf}\left\{\frac{B(S_j)}{\sqrt{2S_j}}\right\} - \sum_{i=0}^{j-1}\left\{1 - \mathrm{erf}\left[\frac{B(S_j) - B(S_i)}{\sqrt{2(S_j - S_i)}}\right]\right\} f(S_i)\frac{\Delta S_{i-1} + \Delta S_i}{2}\right]. \tag{12.122}$$

In the case of constant $\Delta S_i (= \Delta S)$ this can be simplified further:

$$f(S_j) = \frac{2}{\Delta S}\left[1 - \mathrm{erf}\left\{\frac{B(S_j)}{\sqrt{2S_j}}\right\}\right] - 2\sum_{i=0}^{j-1}\left\{1 - \mathrm{erf}\left[\frac{B(S_j) - B(S_i)}{\sqrt{2(S_j - S_i)}}\right]\right\} f(S_i). \tag{12.123}$$

In either case (i.e. eqns. 12.122 and 12.123) solution proceeds recursively: $f(S_0) = 0$ by definition, $f(S_1)$ depends only on the known barrier and $f(S_0)$, $f(S_j)$ depends only on the known barrier and $f(S_{<j})$.

The first crossing rate is computed using the same method but with an effective barrier which is offset by the position of the progenitor in the (δ, S) plane, plus a small shift in time. The non-crossing rate is computed directly by integrating over the first crossing rate distribution. Note that since the numerical integration occurs only up to a finite maximum S, a non-zero non-crossing rate will be computed for CDM-like barriers even though in reality they should have zero non-crossing rate. As such, use of this method for such barriers is not recommended.

12.14.3. Zhang & Hui (2006)

Selected with `excursionSetFirstCrossingMethod=ZhangHui2006` this method solves the barrier first crossing problem using the method of Zhang and Hui [2006]. First crossing (and non-crossing) rates are not supported by this method.

12.14.4. Zhang & Hui (2006) Higher Order

Selected with `excursionSetFirstCrossingMethod=ZhangHui2006HighOrder` this method solves the barrier first crossing problem using a higher-order extension of the method of Zhang and Hui [2006]. First crossing (and non-crossing) rates are not supported by this method.

In this method we discretize the first-crossing distribution function, and use a closed Newton-Cotes method to perform integrations. First, we mesh the S space using uniform spacing in S:

$$S_i = i \times \Delta S, i = 0, 1, \ldots, N, \Delta S = \frac{S}{N}. \tag{12.124}$$

Then we discretize the integral equation by Boole's rule. The integral equation becomes a set of linear algebraic equations:

$$\begin{aligned} f(S_i) &= g_1(S_i) + \frac{\Delta S}{90}\sum_{j=0:4}^{i-4}\{7f(S_j)g_2(S_i,S_j) + 32f(S_{j+1})g_2(S_i,S_{j+1}) \\ &\quad + 12f(S_{j+2})g_2(S_i,S_{j+2}) + 32f(S_{j+3})g_2(S_i,S_{j+3}) + 7f(S_{j+4})g_2(S_i,S_{j+4})\} \end{aligned} \tag{12.125}$$

Since $g_2(S, S')$ approaches infinity when S approaches S', one needs to define $g_2(S_i, S_i)$ carefully when $j = i$. We can rewrite the equation:

$$\begin{aligned} f(S_i) &= g_1(S_i) + \frac{4\Delta S}{90}\sum_{j=0:4}^{i-8}\{7f(S_j)g_2(S_i,S_j) + 32f(S_{j+1})g_2(S_i,S_{j+1}) \\ &\quad + 12f(S_{j+2})g_2(S_i,S_{j+2}) + 32f(S_{j+3})g_2(S_i,S_{j+3}) + 7f(S_{j+4})g_2(S_i,S_{j+4})\} \\ &\quad + \frac{4\bar{g}_2(S_i)\Delta S}{90}\Big(7f(S_{i-4}) + 32f(S_{i-3}) + 12f(S_{i-2}) + 32f(S_{i-1}) + 7f(S_i)\Big). \end{aligned} \tag{12.126}$$

For $\bar{g}_2(S_i)$ we have:

$$\bar{g}_2(S_i) = \frac{1}{\delta S}\int_{S-\delta S}^{S} g_2(S, S')\mathrm{d}S'. \tag{12.127}$$

In the above, δS depends on the range of the previous integral part. Generally, δS is equal to $4\Delta S$. The above equation can be solved for $f(S_i)$, giving:

$$\begin{aligned} f(S_i) &= \Bigg(g_1(S_i) + \frac{4\Delta S}{90} \sum_{j=0:4}^{i-8} \{7f(S_j)g_2(S_i,S_j) + 32f(S_{j+1})g_2(S_i,S_{j+1}) \\ &\quad + 12f(S_{j+2})g_2(S_i,S_{j+2}) + 32f(S_{j+3})g_2(S_i,S_{j+3}) + 7f(S_{j+4})g_2(S_i,S_{j+4})\} \\ &\quad + \frac{4\bar{g}_2(S_i)\Delta S}{90}\Big(7f(S_{i-4}) + 32f(S_{i-3}) + 12f(S_{i-2}) + 32f(S_{i-1})\Big)\Bigg) \\ &\quad \times \left(1 - \frac{4\bar{g}_2(S_i)\Delta S}{90}\right)^{-1}. \end{aligned} \tag{12.128}$$

Not all of the i's are divisible by 4. So, for the first m^{th} spaces, we need to calculate the integral part, separately, where m is the remainder of i by the modulus of 4. It is a good approximation to calculate the first part linearly. Consequently, the final formula for the general problem is:

$$\begin{aligned} f(S_i) &= \Bigg(g_1(S_i) + \frac{\Delta S}{2} \sum_{j=0}^{m-1} \Big(f(S_j)g_2(S_i,S_j) + f(S_{j+1})g_2(S_i,S_{j+1})\Big) \\ &\quad + \frac{4\Delta S}{90} \sum_{\frac{j-m}{4}=0}^{i-8} \{7f(S_j)g_2(S_i,S_j) + 32f(S_{j+1})g_2(S_i,S_{j+1}) \\ &\quad + 12f(S_{j+2})g_2(S_i,S_{j+2}) + 32f(S_{j+3})g_2(S_i,S_{j+3}) + 7f(S_{j+4})g_2(S_i,S_{j+4})\} \\ &\quad + \frac{4\bar{g}_2(S_i)\Delta S}{90}\Big(7f(S_{i-4}) + 32f(S_{i-3}) + 12f(S_{i-2}) + 32f(S_{i-1})\Big)\Bigg) \\ &\quad \times \left(1 - \frac{4\bar{g}_2(S_i)\Delta S}{90}\right)^{-1}. \end{aligned} \tag{12.129}$$

Finally, we can solve the first-crossing distribution function, giving:

$$f(S_0) = g_1(S_0) = 0 \tag{12.130}$$

$$f(S_1) = g_1(S_1)\left(1 - \frac{\bar{g}_2(S_1)\Delta S}{2}\right)^{-1} \tag{12.131}$$

$$f(S_2) = \left(g_1(S_2) + \frac{\Delta S}{2} 2\bar{g}_2(S_2) f(S_1)\right)\left(1 - \frac{\bar{g}_2(S_2)\Delta S}{2}\right)^{-1} \tag{12.132}$$

$$f(S_3) = \left(g_1(S_2) + \frac{\Delta S}{2} 2\bar{g}_2(S_3)(f(S_1) + f(S_2))\right)\left(1 - \frac{\bar{g}_2(S_3)\Delta S}{2}\right)^{-1} \tag{12.133}$$

$$\begin{aligned} f(S_i) = & \left(g_1(S_i) + \frac{\Delta S}{2}\sum_{j=0}^{m-1}\left(f(S_j)g_2(S_i,S_j) + f(S_{j+1})g_2(S_i,S_{j+1})\right)\right. \\ & + \frac{4\Delta S}{90}\sum_{\frac{j-m}{4}=0}^{i-8}\{7f(S_j)g_2(S_i,S_j) + 32f(S_{j+1})g_2(S_i,S_{j+1}) \\ & + 12f(S_{j+2})g_2(S_i,S_{j+2}) + 32f(S_{j+3})g_2(S_i,S_{j+3}) + 7f(S_{j+4})g_2(S_i,S_{j+4})\} \\ & \left. + \frac{4\bar{g}_2(S_i)\Delta S}{90}\left(7f(S_{i-4}) + 32f(S_{i-3}) + 12f(S_{i-2}) + 32f(S_{i-1})\right)\right) \\ & \times\left(1 - \frac{4\bar{g}_2(S_i)\Delta S}{90}\right)^{-1}, \end{aligned} \tag{12.134}$$

where $\bar{g}_2(S_1)$ is defined as:

$$\bar{g}_2(S_1) = \frac{1}{\Delta S}\int_0^{S_1} g_2(S,S')\mathrm{d}S' \text{ if } i = 1 \tag{12.135}$$

$$\bar{g}_2(S_2) = \frac{1}{2\Delta S}\int_0^{S_2} g_2(S,S')\mathrm{d}S' \text{ if } i = 0 \tag{12.136}$$

$$\bar{g}_2(S_3) = \frac{1}{3\Delta S}\int_0^{S_3} g_2(S,S')\mathrm{d}S' \text{ if } i = 0 \tag{12.137}$$

$$\bar{g}_2(S_i) = \frac{1}{4\Delta S}\int_{S_i-4\Delta S}^{S_i} g_2(S,S')\mathrm{d}S' \text{ if } i > 3. \tag{12.138}$$

The error term for this method of discretization is:

$$\epsilon = \frac{(\delta S)^7}{1935360} f^{(6)}(\xi), \tag{12.139}$$

where $f^{(6)}(\xi)$ is the absolute maximum of the sixth derivative in the range of $[S_i, S_i + \delta S]$. For this problem, $\delta S = 4\Delta S$, so:

$$\epsilon \leq \frac{(\Delta S)^7}{118.125} f^{(6)}(\xi). \tag{12.140}$$

Since there are $N/4$ intervals, the maximum deviation from the real value of the function is:

$$\epsilon \leq \sum_{i=1}\frac{N}{4}\frac{(\Delta S)^7}{118.125} f^{(6)}(\xi_i) \leq N4\frac{(\Delta S)^7}{472.5} f^{(6)}(\xi),$$

where $f^{(6)}(\xi)$ is the absolute maximum of the sixth derivative in the domain, $[0, S]$.

12.15. Excursion Set Barrier Remapping

Remappins of the excursion set barrier are selected via the `excursionSetBarrierRemapMethods` (for calculations of first crossing distributions) and `excursionSetBarrierRatesRemapMethods` (for calculations of first crossing rate distributions) parameters. The parameters may specify multiple remappings—these will be applied to the barrier in order.

12.15.1. Null Remapping

Selected with `excursionSetBarrier(Rates)RemapMethods=null` this method leaves the barrier unmodified.

12.15.2. Scale Remapping

Selected with `excursionSetBarrier(Rates)RemapMethods=scale` this method multiplies the barrier by `[excursionSetBarrierRemapScalingFactor]`.

12.15.3. Sheth-Mo-Tormen Remapping

Selected with `excursionSetBarrier(Rates)RemapMethods=Sheth-Mo-Tormen` this method remaps the barrier according to the algorithm of Sheth et al. [2001]:

$$B(S) \rightarrow \sqrt{A}B(S)\left(1+b\left[\frac{S}{AB^2(S)}\right]^c\right), \tag{12.141}$$

where $A=0.707$, $b=0.5$, and $c=0.6$.

12.16. Galactic Structure

The algorithm to be used when solving for galactic structure (specifically, finding radii of galactic components) is selected via the `galacticStructureRadiusSolverMethod` parameter.

12.16.1. Fixed

Selected with `galacticStructureRadiusSolverMethod=fixed` this method determines the sizes of galactic components by assuming that radius equals

$$r = f_\mathrm{r}\lambda r_0 \tag{12.142}$$

where r_0 is the virial or turnaround radius of the node if `[galacticStructureRadiiFixedRadius]=virialRadius` or `turnaround` respectively, λ is its spin parameter and $f_\mathrm{r}=$`[galacticStructureRadiiFixedFactor]` is a parameter.

12.16.2. Linear

Selected with `galacticStructureRadiusSolverMethod=linear` this method determines the sizes of galactic components by assuming that radius scales linearly with specific angular momentum such that

$$r = r_\mathrm{vir} j / j_\mathrm{vir} \tag{12.143}$$

where j is the specific angular momentum of the component (at whatever point in the profile is to be solved for), r is radius, r_vir is the virial radius of the node and $j_\mathrm{vir} = r_\mathrm{vir} v_\mathrm{vir}$ with v_vir being the virial velocity of the node.

12.16.3. Simple

Selected with `galacticStructureRadiusSolverMethod=simple` this method determines the sizes of galactic components by assuming that their self-gravity is negligible (i.e. that the gravitational potential well is dominated by dark matter) and that, therefore, baryons do not modify the dark matter density profile. The radius of a given component is then found by solving

$$j = \sqrt{\mathrm{G} M_\mathrm{DM}(r) r}, \tag{12.144}$$

where j is the specific angular momentum of the component (at whatever point in the profile is to be solved for), r is radius and $M(r)$ is the mass of dark matter within radius r. The parameter `[adiabaticContractionUseFormationHalo]` controls whether the structure of the galaxy will be solved for using the properties of its present node or those of its node at the time of node formation (which requires that "node formation" has been suitably defined and implemented by a component).

12.16.4. Adiabatic

Selected with `galacticStructureRadiusSolverMethod=adiabatic`, this method takes into account the baryonic self-gravity of all galactic components when solving for structure and additionally accounts for backreaction of the baryons on the dark matter density profile. Solution proceeds via an iterative procedure to find equilibrium radii for all galaxies in a consistently contracted halo. To account for adiabatic contraction the mass of dark matter within a given radius r_f is taken to be equal to that originally within radius r_i in the uncontracted halo. This initial radius is computed using the selected galactic structure solver initial radius algorithm (see §12.17). The parameter `[adiabaticContractionUseFormationHalo]` controls whether the structure of the galaxy will be solved for using the properties of its present node or those of its node at the time of node formation (which requires that "node formation" has been suitably defined and implemented by a component).

12.17. Galactic Structure Initial Radii

The algorithm to be used when solving for the initial radius in the dark matter halo when computing galactic structure is selected via the `galacticStructureRadiusSolverInitialRadiusMethod` parameter.

12.17.1. Static

Selected with `galacticStructureRadiusSolverInitialRadiusMethod=static` this method assumes that the dark matter halo is static and so sets the initial radius equal to the final radius.

12.17.2. Adiabatic

Selected with `galacticStructureRadiusSolverInitialRadiusMethod=adiabatic` this method assumes that adiabatic contraction follows the algorithm of Gnedin et al. [2004]. The parameters A and ω of that model are specified via input parameters `adiabaticContractionGnedinA` and `adiabaticContractionGnedinOmega` respectively.

Given the final radius, r_f, the corresponding initial radius, r_i, is found by solving:

$$f_\mathrm{i} M_\mathrm{total,0}(\bar{r}_\mathrm{i}) r_\mathrm{i} = f_\mathrm{f} M_\mathrm{total,0}(\bar{r}_\mathrm{i}) r_\mathrm{f} + V_\mathrm{b}^2(\bar{r}_\mathrm{f}) \bar{r}_\mathrm{f} r_\mathrm{f} / \mathrm{G}, \tag{12.145}$$

where $M_\mathrm{total,0}(r)$ is the initial total matter profile, $V_\mathrm{b}(r)$ is the baryonic contribution to the rotation curve, f_i, is the fraction of mass within the virial radius compared to the node mass[1], $f_\mathrm{f} = (\Omega_\mathrm{M} -$

[1] In Galacticus the "node mass" refers to the total mass of the node, assuming it has the universal complement of baryons. Since some halos may contain less than the complete complement of baryons it is possible that $f_\mathrm{i} < 1$.

$\Omega_\mathrm{b})/\Omega_\mathrm{M} + M_\mathrm{satellite,baryonic}/M_\mathrm{total}$, $M_\mathrm{satellite,baryonic}$ is the baryonic mass in any satellite halos, M_total is the node mass, and

$$\frac{\bar{r}}{r_\mathrm{vir}} = A\left(\frac{r}{r_\mathrm{vir}}\right)^{\omega}, \tag{12.146}$$

where r_vir is the virial radius. Note that we explicitly assume that the initial, uncontracted total density profile has the same shape as the initial dark matter density profile, that contraction of the halo occurs with no shell crossing, and that satellite halos trace the dark matter profile of their host halo.

The derivative, $\mathrm{d}r_\mathrm{f}/\mathrm{d}d_\mathrm{i} \equiv r'_\mathrm{i}$ is found by taking the derivative of eqn. (12.145) to give:

$$\begin{aligned} & f_\mathrm{i} M_\mathrm{total,0}(\bar{r}_\mathrm{i}) r'_\mathrm{i} + f_\mathrm{i} 4\pi \bar{r}_\mathrm{i}^2 \rho_\mathrm{total,0}(\bar{r}_\mathrm{i}) \frac{\mathrm{d}\bar{r}_\mathrm{i}}{\mathrm{d}r_\mathrm{i}} r_\mathrm{i} r'_\mathrm{i} \\ = \;& f_\mathrm{f} M_\mathrm{total,0}(\bar{r}_\mathrm{i}) + f_\mathrm{i} 4\pi \bar{r}_\mathrm{i}^2 \rho_\mathrm{total,0}(\bar{r}_\mathrm{i}) \frac{\mathrm{d}\bar{r}_\mathrm{i}}{\mathrm{d}r_\mathrm{i}} r_\mathrm{f} r'_\mathrm{i} \\ + \;& V_\mathrm{b}^2(\bar{r}_\mathrm{f})\bar{r}_\mathrm{f}/\mathrm{G} + V_\mathrm{b}^2(\bar{r}_\mathrm{f}) \frac{\mathrm{d}\bar{r}_\mathrm{f}}{\mathrm{d}r_\mathrm{f}} r_\mathrm{f}/\mathrm{G} + \frac{\mathrm{d}V_\mathrm{b}^2}{\mathrm{d}\bar{r}_\mathrm{f}}(\bar{r}_\mathrm{f}) \frac{\mathrm{d}\bar{r}_\mathrm{f}}{\mathrm{d}r_\mathrm{f}} \bar{r}_\mathrm{f} r_\mathrm{f}/\mathrm{G}, \end{aligned} \tag{12.147}$$

where

$$\frac{\mathrm{d}\bar{r}}{\mathrm{d}r} = A\left(\frac{r}{r_\mathrm{vir}}\right)^{\omega-1}, \tag{12.148}$$

and which can then be solved numerically for r'_i.

12.18. Galaxy Merging

The process of merging two galaxies currently involves two algorithms: one which decides how the merger causes mass components from both galaxies to move and one which determines the size of the remnant galaxy spheroid.

12.18.1. Mass Movements

The movement of mass elements in the merging galaxies is determined by the `satelliteMergingMassMovementsMethod` parameter.

Very Simple

Selected with `satelliteMergingMassMovementsMethod=verySimple`, this method assumes that the satellite material is always added to the disk of the host, while the host mass is not moved.

Simple

Selected with `satelliteMergingMassMovementsMethod=simple`, this method implements mass movements according to:

- If $M_\mathrm{satellite} > f_\mathrm{major} M_\mathrm{central}$ then all mass from both satellite and central galaxies moves to the spheroid component of the central galaxy;
- Otherwise: Gas from the satellite moves to the component of the central specified by the `[minorMergerGasMovesTo]` parameter (either "`disk`" or "`spheroid`"), stars from the satellite moves to the spheroid of the central and mass in the central does not move.

Here, f_major = `[majorMergerMassRatio]` is the mass ratio above which a merger is considered to be "major".

Baugh et al. (2005)

Selected with `satelliteMergingMassMovementsMethod=Baugh2005`, this method implements mass movements according to:

- If $M_{\rm satellite} > f_{\rm major} M_{\rm central}$ then all mass from both satellite and central galaxies moves to the spheroid component of the central galaxy;
- Otherwise:
  - If $M_{\rm central,spheroid} < f_{\rm burst} M_{\rm central}$ and the gas fraction in the host equals or exceeds $f_{\rm gas,crit}$ then all gas is moved to the host spheroid, while the host stellar disk remains in place.
  - Otherwise, gas from the satellite moves to the component of the central specified by the `[minorMergerGasMovesTo]` parameter (either "`disk`" or "`spheroid`"), stars from the satellite moves to the spheroid of the central and mass in the central does not move.

Here, $f_{\rm major}$ =`[majorMergerMassRatio]` is the mass ratio above which a merger is considered to be "major", while $f_{\rm burst}$ =`[burstMassRatio]` and $f_{\rm gas,crit}$ =`[burstCriticalGasFraction]`.

12.18.2. Remnant Sizes

The method used to calculate the sizes of merger remnant spheroids is selected by the `satelliteMergingRemnantSizeMethod` parameter.

Null

Selected using `satelliteMergingRemnantSizeMethod=null`, this is a null method which does nothing at all. It is useful, for example, when running Galacticus to study dark matter only (i.e. when no galaxy properties are computed).

Cole et al. (2000)

Selected using `satelliteMergingRemnantSizeMethod=Cole2000`, this method uses the algorithm of Cole et al. [2000] to compute merger remnant spheroid sizes. Specifically

$$\frac{(M_1+M_2)^2}{r_{\rm new}} = \frac{M_1^2}{r_1} + \frac{M_2^2}{r_2} + \frac{f_{\rm orbit}}{c}\frac{M_1 M_2}{r_1+r_2}, \tag{12.149}$$

where M_1 and M_2 are the baryonic masses of the components of the merging galaxies that will end up in the spheroid component of the remnant[2] and r_1 and r_2 are the half mass radii of those same components of the merging galaxies[3], $r_{\rm new}$ is the half mass radius of the spheroidal component of the remnant galaxy and c is a constant which depends on the distribution of the mass. For a Hernquist spheroid $c = 0.40$ can be found by numerical integration while for a exponential disk $c = 0.49$. For simplicity a value of $c = 0.5$ is adopted for all components. The parameter $f_{\rm orbit}$ =`mergerRemnantSizeOrbitalEnergy` depends on the orbital parameters of the galaxy pair. For example, a value of $f_{\rm orbit} = 1$ corresponds to point mass galaxies in circular orbits about their center of mass.

A subtelty arises because the above expression accounts for only the baryonic mass of material which becomes part of the spheroid component of the remnant. In reality, there are additional terms in the energy equation due to the interaction of this material with any dark matter mass in each galaxy and any

[2] Depending on the merging rules (see §12.18.1) not all mass may be placed into the spheroid component of the remnant.
[3] In practice, Galacticus computes a weighted average of the disk and spheroid half-mass radii of each galaxy, with weights equal to the masses of each component (disk and spheroid) which will become part of the spheroid component of the remnant.

baryonic mass of each galaxy which does not become part of the spheroid component of the remnant. To account for this additional matter, an effective boost factor, $f_{\rm boost}$, to the specific angular momentum of each component of each merging galaxy is computed:

$$f_{\rm boost} = \frac{j}{\sqrt{\mathrm{G}Mr_{1/2}}}, \tag{12.150}$$

where j is the specific angular momentum of the component, M is its total baryonic mass and $r_{1/2}$ is its half-mass radius. The mass-weighted mean boost factor is found by combining those of all components which will form part of the spheroid of the remnant. The final specific angular momentum of the remnant spheroid is then given by:

$$j_{\rm new} = \langle f_{\rm boost} \rangle r_{\rm new} V_{\rm new}, \tag{12.151}$$

where

$$V_{\rm new}^2 = \frac{\mathrm{G}(M_1+M_2)}{r_{\rm new}}. \tag{12.152}$$

Covington et al. (2008)

Selected using `satelliteMergingRemnantSizeMethod=Covington2008`, this method uses the algorithm of Covington et al. [2008] to compute merger remnant spheroid sizes. Specifically

$$\frac{(M_1+M_2)^2}{r_{\rm new}} = \left[\frac{M_1^2}{r_1} + \frac{M_2^2}{r_2} + \frac{f_{\rm orbit}}{c}\frac{M_1 M_2}{r_1+r_2}\right](1+f_{\rm gas}C_{\rm rad}), \tag{12.153}$$

where M_1 and M_2 are the baryonic masses of the merging galaxies and r_1 and r_2 are their half mass radii, $r_{\rm new}$ is the half mass radius of the spheroidal component of the remnant galaxy and c is a constant which depends on the distribution of the mass. For a Hernquist spheroid $c = 0.40$ can be found by numerical integration while for a exponential disk $c = 0.49$. For simplicity a value of $c = 0.5$ is adopted for all components. The parameter $f_{\rm orbit}$ =`mergerRemnantSizeOrbitalEnergy` depends on the orbital parameters of the galaxy pair. For example, a value of $f_{\rm orbit} = 1$ corresponds to point mass galaxies in circular orbits about their center of mass. The final term on the right hand side of eqn. (12.153) gives a correction to the final energy of the remnant due to dissipational losses based on the results of Covington et al. [2011], with

$$f_{\rm gas} = \frac{M_{1,\rm gas}+M_{2,\rm gas}}{M_1+M_2} \tag{12.154}$$

begin the gas fraction of the progenitor galaxies. By default, $C_{\rm rad} = 2.75$ [Covington et al., 2011]. To account for the effects of dark matter and non-spheroid baryonic matter the same approach is used as in the Cole et al. [2000] algorithm (see §12.18.2).

12.18.3. Progenitor Properties

The method used to calculate the properties of merger progenitor galaxies is selected by the `satelliteMergingRemnantProgen` parameter.

Cole et al. (2000)

Selected using `satelliteMergingRemnantProgenitorPropertiesMethod=Cole2000`, this method uses the algorithms of Cole et al. [2000] to compute progenitor properties. Masses of progenitors are set to

$$M_{\rm host|satellite} = \sum_{i=\rm disk|spheroid} \sum_{j=\rm stars|gas} M_{i,j}, \tag{12.155}$$

where $M_{i,j}$ is the mass of mass type j in component i. Masses of progenitors that will end up in the remnant spheroid are set to

$$M_{\rm spheroid\ host|satellite} = \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j}\delta_{i,j}, \tag{12.156}$$

where $\delta_{i,j} = 0$ of mass type j in component i will end up in the remnant spheroid and 0 otherwise. Radii of material that will end up in the spheroid are set by finding the solution to:

$$\sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j}(r)\delta_{i,j} = \frac{1}{2} \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j}\delta_{i,j}, \tag{12.157}$$

such that the radii are the half-mass radii of the material that will end up in the remnant spheroid. Finally, the angular momentum factor is set to

$$f_{\rm AM\ host|satellite} = \frac{1}{M_{\rm spheroid\ host|satellite}} \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j} \frac{J_{i,j}}{{\rm G}M_{i,j}^{3/2} r_{1/2\ i,j}} \delta_{i,j}, \tag{12.158}$$

where $J_{i,j}$ is the angular momentum or pseudo-angular momentum of mass type j in component i[4].

Standard

Selected using `satelliteMergingRemnantProgenitorPropertiesMethod=standard`, this is the standard method to compute progenitor properties. Masses of progenitors are set to

$$M_{\rm host|satellite} = \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j}, \tag{12.159}$$

where $M_{i,j}$ is the mass of mass type j in component i. Masses of progenitors that will end up in the remnant spheroid are set to

$$M_{\rm spheroid\ host|satellite} = \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j}\delta_{i,j}, \tag{12.160}$$

where $\delta_{i,j} = 0$ of mass type j in component i will end up in the remnant spheroid and 0 otherwise. Radii of material that will end up in the spheroid are set to

$$r_{\rm host|satellite} = \frac{1}{M_{\rm spheroid\ host|satellite}} \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j} r_{1/2\ i,j} \delta_{i,j}. \tag{12.161}$$

Finally, the angular momentum factor is set to

$$f_{\rm AM\ host|satellite} = \frac{1}{M_{\rm spheroid\ host|satellite}} \sum_{i={\rm disk|spheroid}} \sum_{j={\rm stars|gas}} M_{i,j} \frac{J_{i,j}}{{\rm G}M_{i,j}^{3/2} r_{1/2\ i,j}} \delta_{i,j}, \tag{12.162}$$

where $J_{i,j}$ is the angular momentum or pseudo-angular momentum of mass type j in component i.

[4] This is technically not quite what Cole et al. [2000] do. Instead, when computing the masses of the material which ends up in the spheroid they include twice the mass of dark matter (accounting for the effects of adiabatic contraction) within the half-mass radius of each galaxy (as calculated above). The final angular momentum is then $j = \sqrt{{\rm G}M_{\rm remnant} r_{\rm remnant}/2}$ (where $M_{\rm remnant}$ includes the contribution from dark matter and the factor of 2 appears to make this the half-mass). This approach is currently not used in Galacticus since there is no way to get the mass of dark matter enclosed accounting for adiabatic contraction in the general case. This is a solvable problem, and so this algorithm is expected to be modified to match that of Cole et al. [2000] precisely in a future version of Galacticus.

12.19. Gravitational Lensing

The method to be used for computing the effects of gravitational lensing by large-scale structure is specified by the `gravitationalLensingMethod` parameter.

12.19.1. Takahashi et al. (2011)

Selected with `gravitationalLensingMethod=takahashi2011`, this method utilizes the fitting functions of Takahashi et al. [2011] to compute the effects of gravitational lensing. Specifically, eqn. 11 of Takahashi et al. [2011] is used. The parameters $\kappa_{\rm empty}$ and $\langle\kappa^2\rangle$ are computed from the assumed cosmology and non-linear power spectrum as described by [Takahashi et al., 2011, eqns. 5 and 2 respectively]. The parameters, N_κ, A_κ, and ω_κ of the lensing convergence distribution are determined using the conditions given by [Takahashi et al., 2011, eqn. 9].

12.19.2. Baryonic Modifier

Selected with `gravitationalLensingMethod=baryonicModifier`, this method modifies another gravitational lensing class to approximately account for the effects of baryons on the magnification distribution. The distribution to modify is specified via the `[gravitationalLensingBaryonicModifierOriginalDistribution]` parameter. The modification takes the form:

$$P(\mu) \rightarrow P(\mu) + \min[\alpha, \beta P(\mu)] \tag{12.163}$$

where $\alpha =$`[gravitationalLensingBaryonicModifierAlpha]` and $\beta =$`[gravitationalLensingBaryonicModifierBeta]`. The distribution is then renormalized to ensure that the cumulative probability reaches unity for infinite magnification. As an example, values of $\alpha = 2.05 \times 10^{-3}$ and $\beta = 0.62$ approximately reproduce the results of [Hilbert et al., 2008, their Fig. 1].

12.20. Halo Model Power Spectra Modifiers

The method to be used for modifying power spectra in halo model clustering calculations is specified by the `haloModelPowerSpectrumModifierMethod` parameter.

12.20.1. Null

Selected with `haloModelPowerSpectrumModifierMethod=null`, this method provides no modification.

12.20.2. Traxiality

Selected with `haloModelPowerSpectrumModifierMethod=triaxiality`, this method provides attempts to modify power spectra to approximately account for the effects of halo triaxiality using the results of Smith and Watts [2005]. Specifically, the one- and two-halo power spectra are multiplied by a correction factor, $\Delta^2_{\rm triax}/\Delta^2_{\rm sphere}$, derived from the lower panels of Figures 3 and 2 of Smith and Watts [2005] respectively for their "JS02" profile model. Given the uncertainty in this correction, the power spectrum covariance (if provided) is incremented by $\epsilon^2([\Delta^2_{\rm triax}/\Delta^2_{\rm sphere} - 1] \otimes [\Delta^2_{\rm triax}/\Delta^2_{\rm sphere} - 1)$ where $\epsilon = 0.4$ is chosen to approximate the difference between "continuity" and "JS02" profiles in Smith and Watts [2005].

12.21. Hot Halo Mass Distribution

The algorithm to be used when determining the hot halo mass distribution is selected via the `hotHaloMassDistributionMetho` parameter.

12.21.1. β-profile

Selected with `hotHaloMassDistributionMethod=betaProfile` this method adopts a spherically symmetric β-profile density profile for the hot halo. Specifically,

$$\rho_{\rm hothalo}(r) \propto \left[r^2 + r_{\rm core}^2\right]^{3\beta/2}, \tag{12.164}$$

where the core radius, $r_{\rm core}$, is set using the selected cored profile core radius method (see §12.22). The value of β is specified by the `[hotHaloMassDistributionBeta]` parameter. The profile is normalized such that the current mass in the hot gas profile is contained within the outer radius of the hot halo, $r_{\rm hot,outer}$.

12.21.2. Ricotti (2000)

Selected with `hotHaloMassDistributionMethod=ricotti2000` this method adopts a spherically symmetric β-profile density profile for the hot halo with parameters selected using the fitting function of Ricotti and Shull [2000] who found these by solving for hydrostatic equilibrium in an NFW density profile. Specifically, $\beta = 0.9b$ where

$$b = \frac{2c}{9\Gamma}\left[\log(1+c) - \frac{c}{1+c}\right]^{-1}, \tag{12.165}$$

c is the concentration parameter of the dark matter halo, and Γ is the ratio of virial and gas temperatures, which is assumed to be unity. The core radius is $r_{\rm core} = 0.22 r_{\rm s}$ where $r_{\rm s}$ is the scale radius of the dark matter profile. The profile is normalized such that the current mass in the hot gas profile is contained within the outer radius of the hot halo, $r_{\rm hot,outer}$.

12.21.3. Null

Selected with `hotHaloMassDistributionMethod=null` this method assumes no hot halo mass distribution. It is useful, for example, when performing dark matter-only calculations.

12.21.4. Enzo "hydrostatic"

Selected with `hotHaloMassDistributionMethod=enzoHydrostatic` this method adopts a spherically symmetric density profile for the hot halo motivated by the "hydrostatic" profile available in the ENZO code. Specifically,

$$\rho_{\rm hothalo}(r) \propto \begin{cases} T^{-1} r^{-1} & \text{if } r > r_{\rm core} \\ T^{-1} r_{\rm core}^{-1} & \text{if } r \leq r_{\rm core}, \end{cases} \tag{12.166}$$

where the core radius, $r_{\rm core}$, is set using the selected cored profile core radius method (see §12.22). The profile is normalized such that the current mass in the hot gas profile is contained within the outer radius of the hot halo, $r_{\rm hot,outer}$. Note that the ENZO hydrostatic profile does not include this core, but without introducing this the profile mass can be divergent at small radii.

12.22. Hot Halo Mass Distribution Profile: Cored Profile Core Radius

The algorithm to be used when determining the core radius of cored isothermal hot halo density profiles is selected via the `hotHaloMassDistributionCoreRadiusMethod` parameter.

12.22.1. Growing Core

Selected with `hotHaloMassDistributionCoreRadiusMethod=growingCore`, this method implements a core radius equal to a fraction `[coreRadiusOverScaleRadius]` of the node's dark matter profile scale radius for nodes containing a mass of hot gas equal to the universal baryon fraction times their total mass. For nodes containing less hot gas mass, the core radius is expanded to maintain the same gas density at the virial radius, with a maximum core radius of `[coreRadiusOverVirialRadiusMaximum]` times the node's virial radius.

12.22.2. Virial Fraction

Selected with `hotHaloMassDistributionCoreRadiusMethod=virialRadiusFraction`, this method implements a core radius equal to a fraction `[coreRadiusOverVirialRadius]` of the node's virial radius.

12.23. Hot Halo Ram Pressure Force

The algorithm to be used when determining the ram pressure force due to the hot halo is selected via the `hotHaloRamPressureForceMethod` parameter.

12.23.1. Null

Selected with `hotHaloRamPressureForceMethod=null` this method assumes a zero ram pressure force due to the hot halo.

12.23.2. Font et al. (2008)

Selected with `hotHaloRamPressureForceMethod=Font2008` this method computes the ram pressure force using the algorithm of Font et al. [2008]. Specifically, the ram pressure force is

$$\mathcal{F}_{\rm ram,hot,host} = \rho_{\rm hot,host}(r_{\rm peri}) v^2(r_{\rm peri}), \tag{12.167}$$

where $\rho_{\rm hot,host}(r)$ is the hot halo density profile of the node's host halo, $v(r)$ is the orbital velocity of the node in that host, and $r_{\rm peri}$ is the pericentric radius of the node's orbit.

12.24. Hot Halo Ram Pressure Stripping Radius

The algorithm to be used when determining the radius to which the hot halo is stripped by ram pressure forces is selected via the `hotHaloRamPressureStrippingMethod` parameter.

12.24.1. Virial Radius

Selected with `hotHaloRamPressureStrippingMethod=virialRadius` this method sets the ram pressure stripping radius equal to the virial radius of the halo. The effectively results in no ram pressure stripping.

12.24.2. Font et al. (2008)

Selected with `hotHaloRamPressureStrippingMethod=Font2008` this method computes the ram pressure stripping radius using the algorithm of Font et al. [2008]. Specifically, the radius, $r_{\rm rp}$, is computed as the solution of

$$\alpha_{\rm rp} \frac{G M_{\rm satellite}(r_{\rm rp}) \rho_{\rm hot,satellite}(r_{\rm rp})}{r_{\rm rp}} = \mathcal{F}_{\rm ram,hot,host}, \tag{12.168}$$

where $M_{\rm satellite}(r)$ is the total mass of the satellite within radius r, $\mathcal{F}_{\rm ram,hot,host}$ is the ram pressure force due to the hot halo (computed using the selected hot halo ram pressure force method; see §12.23). The parameter $\alpha_{\rm rp}$ =`[ramPressureStrippingFormFactor]` is a geometric factor of order unity.

12.25. Hot Halo Ram Pressure Stripping Timescale

The algorithm to be used when determining the timescale on which the hot halo is stripped by ram pressure forces is selected via the `hotHaloRamPressureStrippingTimescaleMethod` parameter.

12.25.1. Halo Dynamical Timescale

Selected with `hotHaloRamPressureStrippingTimescaleMethod=haloDynamicalTime` this method sets the ram pressure stripping timecale equal to the dynamical time of the associated halo.

12.25.2. Ram Pressure Acceleration

Selected with `hotHaloRamPressureStrippingTimescaleMethod=ramPressureAcceleration` this method computes the ram pressure stripping timecale from the acceleration imparted by the ram pressure force. Following Roediger and BrÃČÅŠggen [2007] this is approximated as:

$$a_{\rm rampressure} = P_{\rm rampressure}/\Sigma, \tag{12.169}$$

where $P_{\rm rampressure}$ is the ram pressure force per unit area, and Σ is the surface density of gas. The associated timescale to accelerate gas over a distance $r_{\rm outer}$ (the current outer radius of the hot halo) is then:

$$\tau_{\rm rampressure} = \sqrt{2 r_{\rm outer} \Sigma_{\rm outer} / P_{\rm rampressure}}. \tag{12.170}$$

12.26. Hot Halo Outflow Reincorporation

The algorithm to be used when determining the rate at which outflowed gas is reincorporated into the hot halo is selected via the `hotHaloOutflowReincorporationMethod` parameter.

12.26.1. Velocity Maximum Scaling

Selected with `hotHaloOutflowReincorporationMethod=hotHaloOutflowReincorporationVelocityMaximumScaling` this method assumes a reincorporation rate of:

$$\dot{M}_{\rm reincorporation} = M_{\rm outflowed}/t_{\rm reincorporation}, \tag{12.171}$$

where

$$t_{\rm reincorporation} = \tau_{\rm reincorporation} \left(\frac{V_{\rm max}}{200 {\rm km/s}} \right)^{\alpha_{\rm reincorporation}} (1+z)^{\beta_{\rm reincorporation}}, \tag{12.172}$$

where $\tau_{\rm reincorporation}$ =`[hotHaloOutflowReincorporationVlctyMxSclngTimeScale]`, $\alpha_{\rm reincorporation}$ =`[hotHaloOutflowRei` and $\beta_{\rm reincorporation}$ =`[hotHaloOutflowReincorporationVlctyMxSclngRedshiftExponent]`.

12.27. Hot Halo Temperature Profile

The algorithm to be used when determining the hot halo temperature profile is selected via the `hotHaloTemperatureMethod` parameter.

12.27.1. Virial Temperature

Selected with `hotHaloTemperatureMethod=virial` this method assumes an isothermal halo with a temperature equal to the virial temperature of the halo.

12.27.2. Enzo "Hydrostatic"

Selected with `hotHaloTemperatureMethod=enzoHydrostatic` this method assumes the "hydrostatic" temperature profile available in the ENZO code. Specifically,

$$T(r) = \max\left(\frac{\mathrm{G}M(<r)\mu m_\mathrm{H}}{3\mathrm{k_B}r}, T_\mathrm{min}\right), \tag{12.173}$$

where $M(<r)$ is the total mass enclosed within radius r, μ is the primordial mean atomic mass, and T_min =`[enzoHydrostaticTemperatureMinimum]` is a temperature floor introduced so as to avoid the temperature reaching abitrarily low masses.

12.28. Initial Mass Functions

The stellar IMF subsystem supports multiple IMFs and extensible algorithms to select which IMF to use based on the physical conditions of star formation.

12.28.1. Initial Mass Function Selection

The method to use for selecting which IMF to use is specified by the `imfSelectionMethod` parameter.

Fixed

Selected by `imfSelectionMethod=fixed`, this method uses a fixed IMF irrespective of physical conditions. The IMF to use is specified by the `imfSelectionFixed` parameter (e.g. setting this parameter to `Salpeter` selects the Salpeter IMF).

Disk and Spheroid

Selected by `imfSelectionMethod=diskSpheroid`, this method uses different IMFs for star formation in disks and spheroids irrespective of other physical conditions. The IMFs to use are specified by the `imfSelectionDisk` and `imfSelectionSpheroid` parameters (e.g. setting one of these parameters to `Salpeter` selects the Salpeter IMF).

12.28.2. Initial Mass Functions

A variety of different IMF s are available. Each IMF registers itself with the Galacticus IMF subsystem and can then be looked-up by name or internal index. All IMFs are assumed to be continuous in M, unless otherwise noted and normalized to unit mass. Each IMF supplies a recycled fraction and metal yield for use in the instantaneous recycling approximation. These can be set via the parameters `imf[imfName]RecycledInstantaneous` and `imf[imfName]YieldInstantaneous` where `[imfName]` is the name of the IMF. Their default values were computed using Galacticus's internal stellar astrophysics modules for a Solar metallicity population with age of 13.8 Gyr.

Baugh et al. (2005) Top-Heavy

The `Baugh2005TopHeavy` IMF is defined by [Baugh et al., 2005]:

$$\phi(M) \propto M^{-1} \text{ for } 0.15M_\odot < M < 125M_\odot \tag{12.174}$$

BPASS

The `BPASS` IMF is defined by:

$$\phi(M) \propto \begin{cases} M^{-1.30} & \text{for } 0.1M_\odot < M < 0.5M_\odot \\ M^{-2.35} & \text{for } 1M_\odot < M < 120M_\odot \\ 0 & \text{otherwise.} \end{cases} \tag{12.175}$$

Chabrier

The `Chabrier` IMF is defined by [Chabrier, 2001]:

$$\phi(M) \propto \begin{cases} M^{-1} \exp(-[\log_{10}(M/M_\mathrm{c})/\sigma_\mathrm{c}]^2/2) & \text{for } M_\mathrm{l} < M < M_\mathrm{t} \\ M^{\alpha} & \text{for } M_\mathrm{t} < M < M_\mathrm{u} \\ 0 & \text{otherwise,} \end{cases} \tag{12.176}$$

where $\sigma_\mathrm{c} =$`[imfChabrierSigma]`, $M_\mathrm{c} =$`[imfChabrierMass]`$M_\odot$, $\alpha =$`[imfChabrierExponent]`, $M_\mathrm{t} =$`[imfChabrierMassTran`
$M_\mathrm{l} =$`[imfChabrierMassLower]`$M_\odot$, and $M_\mathrm{u} =$`[imfChabrierMassUpper]`$M_\odot$.

Kennicutt

The `Kennicutt` IMF is defined by [Kennicutt, 1983]:

$$\phi(M) \propto \begin{cases} M^{-1.25} & \text{for } 0.10M_\odot < M < 1.00M_\odot \\ M^{-2.00} & \text{for } 1.00M_\odot < M < 2.00M_\odot \\ M^{-2.30} & \text{for } 2.00M_\odot < M < 125M_\odot \\ 0 & \text{otherwise.} \end{cases} \tag{12.177}$$

Kroupa

The `Kroupa` IMF is defined by [Kroupa, 2001]:

$$\phi(M) \propto \begin{cases} M^{-0.3} & \text{for } 0.01M_\odot < M < 0.08M_\odot \\ M^{-1.8} & \text{for } 0.08M_\odot < M < 0.5M_\odot \\ M^{-2.7} & \text{for } 0.5M_\odot < M < 1M_\odot \\ M^{-2.3} & \text{for } 1M_\odot < M < 125M_\odot \\ 0 & \text{otherwise.} \end{cases} \tag{12.178}$$

Miller-Scalo

The `Miller-Scalo` IMF is defined by [Miller and Scalo, 1979]:

$$\phi(M) \propto \begin{cases} M^{-1.25} & \text{for } 0.10M_\odot < M < 1.00M_\odot \\ M^{-2.00} & \text{for } 1.00M_\odot < M < 2.00M_\odot \\ M^{-2.30} & \text{for } 2.00M_\odot < M < 10.0M_\odot \\ M^{-3.30} & \text{for } 10.0M_\odot < M < 125M_\odot \\ 0 & \text{otherwise.} \end{cases} \tag{12.179}$$

Piecewise Power-law

Arbitrary piecewise power-law IMFs can be defined using the `PiecewisePowerLaw` method. The IMF will be constructed such that:

$$\phi(M) \propto M^{\alpha_i} \text{ if } M_i \leq M < M_{i+1}, \tag{12.180}$$

where $i = 1 \ldots N$, the M_i are given by `[imfPiecewisePowerLawMassPoints]` and the α_i are given by `[imfPiecewisePowerLawExponents]`. (Note that `[imfPiecewisePowerLawMassPoints]` must contain $N+1$ elements, while `[imfPiecewisePowerLawExponents]` contains only N elements.) The normalization of each power-law piece is chosen to ensure a continuous IMF that is normalized to unit mass overall.

Salpeter

The `Salpeter` IMF is defined by [Salpeter, 1955]:

$$\phi(M) \propto \begin{cases} M^{-2.35} & \text{for } 0.1M_\odot < M < 125M_\odot \\ 0 & \text{otherwise.} \end{cases} \tag{12.181}$$

Scalo

The `Scalo` IMF is defined by [Scalo, 1986]:

$$\phi(M) \propto \begin{cases} M^{+1.60} & \text{for } 0.10M_\odot < M < 0.18M_\odot \\ M^{-1.01} & \text{for } 0.18M_\odot < M < 0.42M_\odot \\ M^{-2.75} & \text{for } 0.42M_\odot < M < 0.62M_\odot \\ M^{-2.08} & \text{for } 0.62M_\odot < M < 1.18M_\odot \\ M^{-3.50} & \text{for } 1.18M_\odot < M < 3.50M_\odot \\ M^{-2.63} & \text{for } 3.50M_\odot < M < 125M_\odot \\ 0 & \text{otherwise.} \end{cases} \tag{12.182}$$

12.29. Intergalactic Medium State

The thermal and ionization state of the intergalactic medium is implemented by the algorithm selected using the `intergalaticMediumStateMethod` parameter.

12.29.1. Simple

Selected using `intergalaticMediumStateMethod=simple`, this method provides a simple model of reionization in which the universe is assumed to be fully neutral prior to the redshift given by `[igmStateSimpleReionizationRedsh` and fully ionized thereafter. The temperature is given by `[igmStateSimplePreReionizationTemperature]` before reionization, and `[igmStateSimpleReionizationTemperature]` thereafter.

12.29.2. RecFast

Selected using `intergalaticMediumStateMethod=RecFast`, this method computes the state of the intergalactic medium using the RecFast code Seager et al. [2000], Wong et al. [2008]. The RecFast code will be downloaded and run to compute the intergalactic medium state as needed, which will then be stored for future use.

12.29.3. File

Selected using `intergalaticMediumStateMethod=file`, this method reads the state of the intergalactic medium from a file and interpolates in the tabulated results. The HDF5 file containing the table should have the following form:

```
HDF5 "igmState.hdf5" {
GROUP "/" {
   ATTRIBUTE "fileFormat" {
      DATATYPE  H5T_IEEE_F64LE
      DATASPACE  SCALAR
      DATA {

The `electronFraction`, `hIonizedFraction`, `heIonizedFraction`, and `matterTemperature` datasets contain the relevaqnt quantity for each redshift in the `redshift` dataset.

12.30. Chemical State

The chemical state of gas is implemented by the algorithm selected using the `ionizatonStateMethod` parameter.

12.30.1. Atomic Collisional Ionization Equilibrium Using CLOUDY

Selected using `ionizatonStateMethod=atomic_CIE_Cloudy`, this method computes the chemical state using the CLOUDY code and under the assumption of collisional ionization equilibrium with no molecular contribution. Abundances are Solar, except for zero metallicity calculations which use CLOUDY's "primordial" metallicity. The helium abundance for non-zero metallicity is scaled between primordial and Solar values linearly with metallicity. The CLOUDY code will be downloaded and run to compute the cooling function as needed, which will then be stored for future use. As this process is slow, a precomputed table is provided with GALACTICUS. If metallicities outside the range tabulated in this file are required it will be regenerated with an appropriate range.

12.30.2. Collisional Ionization Equilibruim From File

Selected using `ionizatonStateMethod=CIE_from_file`, in this method the chemical state is read from a file specified by the `chemicalStateFile` parameter. The format of this file is specified in §16.4.1. The chemical state is assumed to be computed under conditions of collisional ionization equilibrium and therefore densities scale as ρ. Optional HI and HII densities, if present in the file, will be read and used when returning the densities of "chemical" species.

12.31. Mass Function Incompleteness

The incompleteness of observed mass functions is modeled using the method specified by the `massFunctionIncompletenessMe` parameter.

12.31.1. Complete

Selected with `massFunctionIncompletenessMethod=complete`, this method assumes a fully complete mass function.

12.31.2. Surface brightness

Selected with `massFunctionIncompletenessMethod=surfaceBrightness`, this method models the surface brightness distribution of galaxies as a normal distribution with mean $\langle\mu\rangle(M) = \alpha \log_{10}(M/M_0) + \beta$, with root-variance σ, where $\alpha =$ `[massFunctionIncompletenessSurfaceBrightnessModelSlope]`, $\beta =$ `[massFunctionIncompletenessSurfaceBrightnessZeroPoint]`, and $\sigma =$ `[massFunctionIncompletenessSurfaceBrigh` The completeness is the fraction of this distribution above the surface brightness limit given by `[massFunctionIncompleteness`

12.32. Merger Tree Construction

Merger trees are "constructed[5]" by the method specified by the `mergerTreeConstructMethod` parameter.

12.32.1. Read From File

Selected with `mergerTreeConstructMethod=read`, this method reads merger tree structures from file by the designated importer (see §12.37).

12.32.2. Build

Selected with `mergerTreeConstructMethod=build`, this method first creates a distribution of tree root halo masses and then builds a merger tree using the algorithm specified by the `mergerTreeBuildMethod` parameter.

If `[mergerTreeBuildTreesHaloMassDistribution]=read`, then these masses will be read from a file specified by `[mergerTreeBuildTreeMassesFile]`. Otherwise, the root halo masses are selected to range between `mergerTreeBuildHaloMassMinimum` and `mergerTreeBuildHaloMassMaximum` with `mergerTreeBuildTreesPerDecad` trees per decade of root halo mass on average. Trees are rooted at `mergerTreeBuildTreesBaseRedshift` and tree building will begin with the `mergerTreeBuildTreesBeginAtTree`$^{\rm th}$ tree[6]. The root halo masses are usually drawn from the density function specified by the halo mass function sampling density method (see §12.11.6). The distribution of x is determined by the input parameter `mergerTreeBuildTreesHaloMassDistribution` with options:

`uniform` x is distributed uniformly between 0 and 1;

`quasi` x is distributed using a quasi-random sequence;

`random` x is distributed using a pseudo-random sequence;

`read` halos masses are instead read from a file.

In the case of reading root halo masses from a file, the file can be either an XML or HDF5 file. An XML file should have the following form:

```
<mergerTrees>
 <treeRootMass>13522377303.5998</treeRootMass>
 <treeRootMass>19579530191.8709</treeRootMass>
 <treeRootMass>21061025282.9613</treeRootMass>
 .
 .
 .
 <treeWeight>13522377303.5998</treeWeight>
 <treeWeight>19579530191.8709</treeWeight>
 <treeWeight>21061025282.9613</treeWeight>
 .
 .
 .
</mergerTrees>
```

[5] By "construct" we mean any process of creating a representation of a merger tree within Galacticus.

[6] This will normally be set to 1 to begin with the first tree. Other values allow to begin on later trees for debugging purposes.

where each `treeRootMass` element gives the mass (in Solar masses) of the root halo of a tree to generate, and the (optional) `treeWeight` elements give the corresponding weight (in units of Mpc^{-3}) to assign to each tree. An HDF5 file should have the following structure:

```
HDF5 {
GROUP '/' {
   DATASET 'treeRootMass' {
      DATATYPE  H5T_IEEE_F64BE
      DATASPACE  SIMPLE { ( * ) / ( * ) }
   }
   DATASET 'treeWeight' {
      DATATYPE  H5T_IEEE_F64BE
      DATASPACE  SIMPLE { ( * ) / ( * ) }
   }
}
}
```

where the `treeRootMass` dataset contains the mass (in Solar masses) of the root halo of a tree to generate, and the (optional) `treeWeight` dataset contains the weight (in units of Mpc^{-3}) to assign to each tree.

12.32.3. Fully Specified

Selected with `mergerTreeConstructMethod=fullySpecified`, this method will construct a merger tree, and set properties of components in each node, using a description read from an XML document. The document is specified via the `[mergerTreeConstructFullySpecifiedFileName]` input parameter.

The tree specification document looks as follows:

```
<!-- Simple initial conditions test case -->
<initialConditions>

  <node>
    <index>2</index>
    <parent>1</parent>
    <firstChild>-1</firstChild>
    <sibling>-1</sibling>
    <basic>
      <time>1.0</time>
      <timeLastIsolated>1.0</timeLastIsolated>
      <mass>1.0e12</mass>
      <accretionRate>7.9365079e9</accretionRate>
    </basic>
    <spin>
      <spin>0.1</spin>
    </spin>
    <disk>
      <massGas>1.0e10</massGas>
      <angularMomentum>1.0e10</angularMomentum>
      <abundancesGas>
<metals>1.0e9</metals>
<Fe>1.0e9</Fe>
      </abundancesGas>
```

```
    </disk>
  </node>

  <node>
    <index>1</index>
    <parent>-1</parent>
    <firstChild>2</firstChild>
    <sibling>-1</sibling>
    <basic>
      <time>13.8</time>
      <timeLastIsolated>13.8</timeLastIsolated>
      <mass>1.1e12</mass>
      <accretionRate>7.8125e9</accretionRate>
    </basic>
    <position>
      <position>1.23</position>
      <position>6.31</position>
      <position>3.59</position>
    </position>
  </node>

</initialConditions>
```

The document consists of a set of `node` elements, each of which defines a single node in the merger tree. Each `node` element must specify the `index` of the node, along with the index of the node's `parent`, `firstChild`, and `sibling`.

Each `node` element may contain elements which specify the properties of a component in the node. For example, a `basic` element will specify properties of the "basic" component. If multiple elements for a given component type are present, then multiple instances of that component will be created in the node.

Within a component definition element scalar properties are set using an element with the same name as that property (e.g. `mass` in the `basic` components in the above example). Rank-1 properties are set using a list of elements with the same name as the property (e.g. `position` in the `position` component in the above example).

For composite properties (e.g. abundances), the specification element should contain sub-elements that specify each property of the composite. Currently only the `abundances` object supports specification in this way, as detailed below:

`abundances` (See `abundancesGas` in the above example.) The total metal content is specified via a `metals` element. If other elements are being tracked, their content is specified via an element with the short-name of the element (e.g. `Fe` for iron).

12.32.4. Smooth Accretion

Selected with `mergerTreeConstructMethod=smoothAccretion`, this method builds a branchless merger tree with a smooth accretion history using the selected mass accretion history method (see §16.4.1). The tree has a final mass of `mergerTreeHaloMass` (in units of $M_\odot$) at redshift `mergerTreeBaseRedshift` and is continued back in time by decreasing the halo mass by a factor `mergerTreeHaloMassDeclineFactor` at each new node until a specified `mergerTreeHaloMassResolution` (in units of $M_\odot$) is reached.

12.32.5. State Restore

Selected with `mergerTreeConstructMethod=stateRestore`, this method will restore a merger tree whose complete internal state was written to file. It is intended primarily for debugging purposes to allow a tree to begin processing just prior to the point of failure. To use this method, the following procedure should be followed:

1. Identify a point in the evolution of the tree suitably close to, but before, the point of failure;
2. Insert approrpiate code into Galacticus to have it call the function to store the state of the file and then stop, e.g.:

```
use Merger_Trees_State_Store
.
.
.
if (<conditions are met>) then
   call Merger_Tree_State_Store(thisTree,'storedTree.dat')
   stop 'tree internal state was stored'
end if
```

3. Run the model ensuring that `[stateFileRoot]` is set to a suitable file root name to allow the internal state of Galacticus to be stored;
4. Remove the code inserted above and recompile;
5. Run Galacticus with an input parameter file identical to the one used previously except with `[mergerTreeConstructMethod]=stateRestore`, `[stateFileRoot]` removed, `[stateRetrieveFileRoot]` set to the value previously used for `[stateFileRoot]` and `[mergerTreeStateStoreFile]=storedTree.dat`.

This should restore the tree and the internal state of Galacticus precisely from the point where they were saved and produce the same subsequent evolution.

Note that currently this method does not support storing and restoring of trees which contain components that have more than one instance.

12.33. Merger Tree Building Mass Resolution

The method to be used for computing the mass resolution to use when building merger trees is specified by the `mergerTreesBuildMassResolutionMetod` parameter.

12.33.1. Fixed

Selected with `mergerTreesBuildMassResolutionMetod=fixed`, this method assumes a fixed mass resolution of `[mergerTreeBuildMassResolutionFixed]` for all merger trees.

12.33.2. Scaled

Selected with `mergerTreesBuildMassResolutionMetod=scaled`, this method computes the mass resolution to be the larger of `[mergerTreeBuildMassResolutionScaledMinimum]` and `[mergerTreeBuildMassResolutionScaledF` where $M_{\rm base}$ is the base mass of the merger tree.

12.34. Merger Tree Branching

The method to be used for computing branching probabilities in merger trees is specified by the `treeBranchingMethod` parameter.

12.34.1. Modified Press-Schechter

Selected with `treeBranchingMethod=modifiedPress-Schechter`, this method uses the algorithm of Parkinson et al. [2008] to compute branching ratios. The parameters G_0, γ_1 and γ_2 of their algorithm are specified by the input parameters `modifiedPressSchechterG0`, `modifiedPressSchechterGamma1` and `modifiedPressSchechterGamma2` respectively. Additionally, the parameter `modifiedPressSchechterFirstOrderAccuracy` limits the step in $\delta_{\rm crit}$ so that it never exceeds `modifiedPressSchechterFirstOrderAccuracy` $\sqrt{2[\sigma^2(M_2/2)-\sigma^2(M_2)]}$, which ensures the the first order expansion of the merging rate that is assumed is accurate. To find bounds on the branching probability, we make use of the fact that eqn. (4) of Parkinson et al. [2008] can be written as

$$\frac{{\rm d}f}{{\rm d}t} = \frac{{\rm d}t}{{\rm d}\omega}\int_{M_{\rm min}}^{M/2} \frac{M}{M'}\frac{{\rm d}f}{{\rm d}t}\frac{{\rm d}S}{{\rm d}M'}\left|\frac{{\rm d}t}{{\rm d}\omega}\right| G[\omega,\sigma(M),\sigma(M')]{\rm d}M'. \tag{12.183}$$

By holding the M' in the denominator of the first term in the integrand fixed, we obtain an analytic solution to the integral in terms of hypergeometric functions. If we fix this M' at $M_{\rm min}$ we obtain an upper limit on the branching probability, while if we fix it to $M/2$ a lower limit is obtained.

Calculation of branching probabilities involves computation of several hypergeometric functions which are numerically slow. Two parameters control the accuracy and application of these functions. First, `[modifiedPressSchechterHypergeometricPrecision]` ($=10^{-6}$) specifies the fractional tolerance to which these functions should be computed. Second, if `[modifiedPressSchechterTabulateHypergeometricFactors]=true` then these functions will be tabulated for rapid lookup (at some loss of precision).

12.34.2. Generalized Press-Schechter

Selected with `treeBranchingMethod=generalizedPress-Schechter`, this method computes branching probabilities from solutions to the excursion set barrier first crossing rate problem (using the selected `excursionSetFirstCrossingMethod`; see §16.4.1). Specifically, the branching probability per unit time is:

$$\frac{{\rm d}f}{{\rm d}t} = \frac{{\rm d}t}{{\rm d}\omega}\int_{M_{\rm min}}^{M/2} \frac{M}{M'}\frac{{\rm d}f}{{\rm d}t}\frac{{\rm d}S}{{\rm d}M'}\left|\frac{{\rm d}t}{{\rm d}\omega}\right| G[\omega,\sigma(M),\sigma(M')]{\rm d}M', \tag{12.184}$$

where $\omega=\delta_{\rm c,0}/D(t)$. The rate of accretion of mass in halos below the resolution limit of the merger tree is

$$\frac{{\rm d}R}{{\rm d}t} = \frac{{\rm d}t}{{\rm d}\omega}\int_{0}^{M_{\rm min}} \frac{{\rm d}f}{{\rm d}t}\frac{{\rm d}S}{{\rm d}M'}\left|\frac{{\rm d}t}{{\rm d}\omega}\right| G[\omega,\sigma(M),\sigma(M')]{\rm d}M'. \tag{12.185}$$

In the above, $G[\omega,\sigma(M),\sigma(M')]$ is a modification to the merger rate as computed by the selected `treeBranchingModifierMethod` (see §16.4.1). If `[generalizedPressSchechterSmoothAccretion]=true` then smooth accretion (i.e. accretion of matter not in dark matter halos) is accounted for at the rate:

$$\frac{{\rm d}R_{\rm s}}{{\rm d}t} = \frac{{\rm d}t}{{\rm d}\omega}G[\omega,\sigma_{\rm max},\sigma(M')]\frac{{\rm d}\,\widetilde{f}}{{\rm d}t}, \tag{12.186}$$

where $\sigma_{\rm max}$ is the peak value of $\sigma(M)$ (for the lowest mass halos) and ${\rm d}\,\widetilde{f}\,/{\rm d}t$ is the rate at which excursion set trajectories *fail* to cross the barrier on any mass scale.

12.35. Merger Tree Branching Modifier

The method to be used for modifying branching probabilities in merger trees is specified by the `treeBranchingModifierMetho` parameter.

12.35.1. Null

Selected with `treeBranchingModifierMethod=null`, this method makes no change to the branching probability.

12.35.2. Parkinson, Cole & Helly (2008)

Selected with `treeBranchingModifierMethod=Parkinson-Cole-Helly2008`, this method modifies branching probabilities according to the prescription of Parkinson et al. [2008]. Specifically, the branching probability is multiplied by:

$$G(\delta_\mathrm{p},\sigma_\mathrm{c},\sigma_\mathrm{p}) = G_0 \left(\frac{\sigma_\mathrm{p}}{\sigma_\mathrm{p}}\right)^{\gamma_1} \left(\frac{\delta_\mathrm{p}}{\sigma_\mathrm{p}}\right)^{\gamma_2} \tag{12.187}$$

where δ_p is the current critical overdensity for collapse for the parent halo, and σ_c and σ_p are the root-variance of the smooth mass-density field on scales corresponding to the masses of child and parent halos respectively. The parameters of the fit can be adjusted via input parameters: $G_0 =$`[modifiedPressSchechterG0]`, $\gamma_1 =$`[modifiedPressSchechterGamma1]`, and $\gamma_2 =$`[modifiedPressSchechterGamma2]`.

12.36. Merger Tree Building

The method to be used for building merger trees is specified by the `mergerTreeBuildMethod` parameter.

12.36.1. Cole et al. (2000) Algorithm

Selected with `mergerTreeBuildMethod=Cole2000`, this method uses the algorithm described by Cole et al. [2000] (with minor modifications described below), with a branching probability method selected via the `treeBranchingMethod` parameter. This action of this algorithm is controlled by the following parameters:

`mergerTreeBuildCole2000MergeProbability` The maximum probability for a binary merger allowed in a single timestep. This allows the probability to be kept small, such the the probability for multiple mergers within a single timestep is small.

`mergerTreeBuildCole2000AccretionLimit` The maximum fractional change in mass due to sub-esolution accretion allowed in any given timestep when building the tree.

`mergerTreeBuildCole2000HighestRedshift` The highest redshift to which the tree should be built. Any branch reaching this redshift will be terminated. Typically this should be set to a high value such that branches terminate when the resolution limit it reached, but specifying a maximum redshift can be useful in some situations.

`modifiedPressSchechterUseCDMAssumptions` Stronger bounds on the branching probability can be found if certain assumptions[7], which are valid for CDM but not necessarily for other models, are made. Setting this option to `true` allows these assumptions to be used (and will speed up the algorithm).

[7] Specifically, $\alpha(=-\mathrm{d}\log\sigma/\mathrm{d}\log M) > 0$ and $\mathrm{d}\alpha/\mathrm{d}M > 0$ [Parkinson et al., 2008].

`mmergerTreeBuildCole2000BranchIntervalStep` If `true`, instead of limiting each time step such that the probability of branching is less than `mergerTreeBuildCole2000MergeProbability`, the interval to the next branching event will be drawn from a negative exponential with the appropriate rate. If this exceeds the maximum allowed timestep based on other considerations (e.g. the accretion limit), no branching occurs, and the timestep proceeds[8]. If the interval is less than the maximum allowed timestep, branching occurs at that point. In the regime of high branching rates (which occur when the branch being grown is far above the mass resolution), this approach allows for larger timesteps to be taken.

The minimum halo mass that the algorithm will follow is determined by the selection merger tree building mass resolution method (see §12.33). Mass accretion below this scale is treated as smooth accretion and branches are truncated once they fall below this mass.

Modifications

In the original Cole et al. [2000], when a branch split occurred masses, M_2 and M_3, of the two new halos were selected by first drawing the mass M_2 from the branching distribution function in the range $M_{\rm res}$ to $M_1/2$ (where M_1 is the mass of the parent halo, and $M_{\rm res}$ is the mass resolution being used for the tree), and then setting

$$M_3 = M_1(1-F) - M_2 \tag{12.188}$$

where F is the fraction of the parent halo mass gained through sub-resolution accretion in this timestep. As the sub-resolution accretion is removed entirely from the mass M_3 and not from M_2 this can lead to an assymetry in progenitor mass functions close to $M_1/2$. Therefore, we instead set the progenitor masses by first drawing a mass M_2' from the mass branching distribution function and then setting

$$\begin{aligned} M_2 &= M_2'(1-F), \\ M_3 &= (M_1 - M_2')(1-F), \end{aligned} \tag{12.189}$$

which ensures a symmetric treatment of subresolution accretion close to $M_1/2$.

12.37. Merger Tree Importing

When merger trees are to be read from file, a number of different file formats are supported. An "importer" class is used to read these files and place the contents into internal data structures that Galacticus can then manipulate. The importer class to use is specifide by the `[mergerTreeImporterMethod]` parameter.

12.37.1. Galacticus

Selected with `mergerTreeImporterMethod=galacticus`, this method reads merger tree structures from an HDF5 file specified by the `mergerTreeReadFileName` parameter. The structure of these HDF5 files is described in §5.2.

12.37.2. Sussing Merger Trees

Selected with `mergerTreeImporterMethod=sussing`, this method reads merger tree structures from files following the format designed for the "Sussing Merger Trees" workshop [Srisawat et al., 2013], along

[8] Note that we do not have to concern ourselves in the subsequent timestep with the fact that no branching occurred in the previous timestep because of the memorylessness nature of the negative exponential distribution. That is, the distribution of branching intervals conditioned on the fact that no branching occurred in the previous timestep, is just the same negative exponential distribution.

with Amiga's Halo Finder (AHF) format halo catalogs. A descriptor file must be specified via the `[mergerTreeReadFileName]` parameter. This descriptor file should have the following format:

```
simulation.txt
MergerTree+AHF.txt
snapidzred.txt
AHF/62.5_dm_000.z50.000.AHF_halos
AHF/62.5_dm_001.z30.000.AHF_halos
AHF/62.5_dm_002.z19.916.AHF_halos
.
.
.
AHF/62.5_dm_061.z0.000.AHF_halos
```

in which each line specifies a file to be read (by default path names are relative to the location of the descriptor file—fully-qualified path names can also be given).

The first line identifies a file which specifies properties of the simulation. This file should look like:

```
WMAP7 cosmology:
----------------
Omega0          =       0.272
OmegaLambda0    =       0.728
h               =       0.704

simulation:
-----------
B               =       62.5 Mpc/h
N               =       270^3 particles
```

Currently only the cosmological parameter and box length are read from this file.

The second line identifies the merger tree file which must be in the format specified by Srisawat et al. [2013].

The third line of the descriptor file specifies a snapshot file which should have the following format:

```
#    snapnum       a             z          t(t0)      t(year)
           0    0.0196080      49.9996   0.00354284  4.87485e+07
           1    0.0322580      30.0001   0.00747572  1.02864e+08
           2    0.0478110      19.9157    0.0134888  1.85602e+08
           3    0.0519650      18.2437    0.0152842  2.10306e+08
           4    0.0564190      16.7245    0.0172905  2.37912e+08
           5    0.0611880      15.3431    0.0195280  2.68700e+08
           6    0.0662870      14.0859    0.0220186  3.02969e+08
             .
             .
             .
```

This file must contain one line for each snapshot of the simulation, giving the snapshot number, expansion factor, redshift, fractional time (relative to present day), and age of the universe (in years).

Subsequent lines identify the AHF halo files for each snapshot (files can be listed in any order).

Merger tree files of this type can be split into subvolumes before processing. This is useful if the file is too large to read into memory in one go. The number of subvolumes to use (in each of the three dimensions of the simulation cube) is specified by the `[mergerTreeImportSussingSubvolumeCount]` parameter. The

specific subvolume to process is specified by the [mergerTreeImportSussingSubvolumeIndex] parameter, which should give the index (running from 0 to [mergerTreeImportSussingSubvolumeCount] -1) in each dimension (whitespace separated). To ensure that no halos are missed from trees near the edge of the subvolume, a buffer region around the subvolume is also read. The width of this buffer (in units of Mpc$/h$ to follow the format convention) is specified via the [mergerTreeImportSussingSubvolumeBuffer] parameter.

12.38. Merger Tree Pre-evolution Processing

Arbitrary processing of merger trees prior to their evolution can be carried out using the mergerTreePreEvolveTask directive (see §16.4.3). Currently defined tasks are defined below.

12.38.1. Enforce Monotonic Mass Growth

This task enforces monotonic growth a halo mass along each branch of each merger tree. It does this by searching the tree for nodes which are less massive than the sum of the masses of their immediate progenitors, and increasing the mass of such nodes to equal the sum of the masses of their immediate progenitors. To enforce monotonic mass growth along branches set [mergerTreeEnforceMonotonicGrowth]=true.

12.38.2. Interpolate Tree to Time Grid

This task will interpolate the merger tree structure onto a new array of timesteps if [mergerTreeRegridTimes]=true. The timestep array is specified via the parameters:

[mergerTreeRegridSpacing] The spacing of the timesteps. Five options are available: linear will space timesteps uniformly in expansion factor, logarithmic will space timesteps uniformly in the logarithm of expansion factor, logCriticalDensity will space timesteps uniformly in the logarithm of critical density, δ_c, millennium will use times corresponding to the redshifts of snapshots in the Millennium Simulation database, while read will use times corresponding to the redshifts specified in the mergerTreeRegridRedshifts parameter;

[mergerTreeRegridStartExpansionFactor] The smallest expansion factor in the array (ignored for millennium and read spacings);

[mergerTreeRegridEndExpansionFactor] The largest expansion factor in the array (ignored for millennium and read spacings);

[mergerTreeRegridCount] The number of timesteps in the array;

Along each branch of the tree, new halos are inserted at times corresponding to the times in the resulting array. The masses of these nodes are linearly interpolated between the existing nodes on the branch. Once these new nodes have been added, all other nodes are removed from the tree[9] The processing is useful to construct representations of trees as they would be if only sparse time sampling were available. As such, it is useful for exploring how the number of snapshots in merger trees extracted from N-body simulations affects the properties of galaxies that form in them.

[9] The base node of the tree is never removed, even if it does not lie on one of the times in the constructed array.

12.38.3. Mass Accretion History Output

Output of the mass accretion history (i.e. the mass of the node on the primary branch as a function of time) for each merger tree can be requested by setting `[massAccretionHistoryOutput]=true`. If requested, an additional group, `massAccretionHistories`, is made in the GALACTICUS output file. This group will contain a subgroup for each merger tree (`mergerTreeN` where `N` is the merger tree index) within which three datasets, `nodeIndex`, `nodeTime` and `nodeMass`, can be found. These give the index, time and mass of the node on the primary branch of the tree at all times for which the tree is defined.

12.38.4. Tree Pruning By Mass

This task allows for branches of merger trees to be pruned—i.e. nodes below a specified mass limit are removed from the tree prior to any evolution. This can be useful for convergence studies for example. To prune branches set `[mergerTreePruneBranches]=true` and set `[mergerTreePruningMassThreshold]` to the desired mass threshold below which nodes will be pruned.

12.38.5. Tree Pruning By Hierarchy

This task allows for branches of merger trees to be pruned by hierarchy—i.e. nodes below a given depth in the hierarchy[10] are removed from the tree prior to any evolution. To prune branches by hierarchy depth set `[mergerTreePruneHierarchyAtDepth]` to the desired depth at which to prune. For example, a value of 1 will result in all branches except for the main branch being removed, while a value of 2 will remove all branches that do not merge directly onto the main branch. (Note that setting `[mergerTreePruneHierarchyAtDepth]` to zero will result in no pruning.)

12.38.6. Tree Pruning By Essential Node

This task allows for branches of merger trees to be pruned to leave only the branch occupied by an "essential" node, along with any progenitor branches of that node. This is intended primarily for debugging purposes where it can be convenient to cut away all non-essential branches of the tree. This pruning task is activated by setting `[mergerTreePruneNonEssential]=true`. The essential node is specified by `[mergerTreePruningNonEssentialID]` and `[mergerTreePruningNonEssentialTime]`, which specify the index of the node, and the time at which its properties are required. Specifying the time is important—if the node is a satellite at this time, then the pruning will not remove any progenitors of the parent node in which the essential node lives at the specified time.

12.39. Chemical Reaction Rates

Methods for computing chemical reaction rates are selected via the `[chemicalReactionRatesMethods]` parameter. Multiple methods can be selected—their rates are cumulated.

12.39.1. Null

Selected with `chemicalReactionRatesMethods=null` this is a null method which does not set any rates.

[10] The main branch is defined as depth 0. Other branches are assigned a depth equal to the depth of the branch onto which they merge plus 1. For example, any branch which merges directly onto the main branch is defined as depth 1.

12.39.2. Hydrogen Network

Selected with `chemicalReactionRatesMethods=hydrogenNetwork` this method computes rates using the network of reactions and fitting functions from Abel et al. [1997] and Tegmark et al. [1997]. The parameter `[hydrogenNetworkFast]` controls the approximations made. If set `true` then H^- is assumed to be at equilibrium abundance, H_2^+ reactions are ignored and other slow reactions are ignored (see Abel et al. 1997).

12.40. Ram Pressure Induced Mass Loss Rates in Disks/Spheroids

The methods for computing ram pressure induced rates of mass loss in disks/spheroids are selected via the `ramPressureStrippingMassLossRate(Disks|Spheroids)Method` parameter.

12.40.1. Simple

Selected with `ramPressureStrippingMassLossRate(Disks|Spheroids)Method=simple` this method computes the mass loss rate to be, for disks:

$$\dot{M}_{\rm gas,disk} = \min\left(\frac{\mathcal{F}_{\rm hot,host}}{2\pi {\rm G}\Sigma_{\rm gas}(r_{\rm half})\Sigma_{\rm total}(r_{\rm half})}, R_{\rm maximum}\right)\frac{M_{\rm gas,disk}}{\tau_{\rm dyn,disk}}, \tag{12.190}$$

where $\mathcal{F}_{\rm hot,host}$ is the ram pressure force due to the hot halo of the node's host (computed using the selected hot halo ram pressure force method; see §12.23), $\Sigma_{\rm gas}(r)$ is the gas surface density in the disk, $\Sigma_{\rm total}(r)$ is the total surface density in the disk, $r_{\rm half}$ is the disk half-mass radius, $M_{\rm gas,disk}$ is the total gas mass in the disk, $\tau_{\rm dyn,disk} = r_{\rm disk}/v_{\rm disk}$ is the dynamical time in the disk, and $R_{\rm maximum}$ =`[ramPressureStrippingMassLossRateDiskSimp` controls the maximum allowed rate of mass loss. For spheroids the mass loss rate is:

$$\dot{M}_{\rm gas} = -\max(\alpha, R_{\rm maximum})M_{\rm gas}/\tau_{\rm spheroid}, \tag{12.191}$$

where $R_{\rm maximum}$ =`[ramPressureStrippingMassLossRateSpheroidSimpleFractionalRateMax]`

$$\alpha = \mathcal{F}_{\rm hot,host}/F_{\rm gravity}, \tag{12.192}$$

and,

$$F_{\rm gravity} = \frac{4}{3}\rho_{\rm gas}(r_{1/2})\frac{{\rm G}M_{\rm total}(r_{1/2})}{r_{1/2}} \tag{12.193}$$

is the gravitational restoring force in the spheroid at the half-mass radius, $r_{1/2}$ [Takeda et al., 1984].

12.40.2. Null

Selected with `ramPressureStrippingMassLossRate(Disks|Spheroids)Method=null` this method assumes zero mass loss rate always.

12.41. Satellite Dynamical Friction

The method to be used for computing the satellite vector acceleration due to dynamical friction is specified by the `satelliteDynamicalFrictionMethod` parameter.

12.41.1. Null

Selected with `satelliteDynamicalFrictionMethod=null`, this method assumes that there is no dynamical friction in the system.

12.41.2. Chandrasekhar (1943)

Selected with `satelliteDynamicalFrictionMethod=Chandrasekhar1943`, this method uses the Chandrasekhar [1943] formula to compute the acceleration of a satellite at radius r from the center of the host due to dynamical friction:

$$\mathbf{a}_{DF} = -\frac{4\pi \mathrm{G}^2 M_{\rm sat} \rho_{\rm host}(r)}{v_{\rm sat}^3} \ln\Lambda \left[\mathrm{erf}(x) - \frac{2x}{\sqrt{\pi}} \exp(-x^2)\right] \mathbf{v}_{\rm sat}, \tag{12.194}$$

where $M_{\rm sat}$ and $\mathbf{v}_{\rm sat}$ are the satellite's mass and velocity, respectively, $v_{\rm sat} = |\mathbf{v}_{\rm sat}|$, $\rho_{\rm host}(r)$ is the host's density profile, $\ln\Lambda =$`[satelliteDynamicalFrictionChandrasekharCoulombLogarithm]` is the Coulomb logarithm, and $x \equiv v_{\rm sat}/\sqrt{2}\sigma(r)$, where $\sigma(r)$ is the velocity dispersion of the host halo at radius r, approximated to be equal to the host virial velocity, $v_{\rm vir}$.

12.42. Satellite Tidal Fields

The method for computing the tidal field experienced by satellite galaxies is selected via `satellitesTidalFieldMethod`.

12.42.1. Null

Selected with `satellitesTidalFieldMethod=null` this method assumes a zero tidal field always.

12.42.2. Spherical Symmetry

Selected with `satellitesTidalFieldMethod=sphericalSymmetry` this method assumes a spherically-symmetric host halo, and computes the tidal field accordingly using:

$$\mathcal{F} = \frac{\mathrm{G}M_{\rm host}(< r_{\rm p})}{r_{\rm p}^3} - 4\pi \mathrm{G}\rho_{\rm host}(r_{\rm p}) + \omega_{\rm p}^2, \tag{12.195}$$

where $r_{\rm p}$ is the pericentric radius. $M_{\rm host}(< r)$ is the mass of the host halo enclosed within a sphere of radius r, $\rho_{\rm host}(r)$ is the host density at radius r, and $\omega_{\rm p}$ is the orbital angular velocity at pericenter.

12.43. Satellite Tidal Stripping

The method to be used for computing the satellite mass loss rate due to tidal stripping is specified by the `satelliteTidalStrippingMethod` parameter.

12.43.1. Null

Selected with `satelliteTidalStrippingMethod=null`, this method assumes that there is no tidal stripping in the system.

12.43.2. Zentner (2005)

Selected by default with `satelliteTidalStrippingMethod=Zentner2005`, this method uses the formalism of Zentner et al. [2005] to compute the mass loss rate $\dot{M}_{\rm sat}$:

$$\dot{M}_{\rm sat} = -\alpha \frac{M_{\rm sat}(> r_{\rm tidal})}{T_{\rm orb}}, \tag{12.196}$$

where $\alpha =$ `[satelliteTidalStrippingZentnerRate]`,

$$T_{\rm orb} = \frac{1}{\max(\omega/2\pi, v_{\rm r}/r)}, \tag{12.197}$$

where ω is the angular velocity of the satellite, $v_{\rm r}$ is the radial velocity, r is the orbital radius, and $r_{\rm tidal}$ is the tidal radius of the satellite, given by the King [1962] formula:

$$r_{\rm tidal} = \left(\frac{GM_{\rm sat}}{\omega^2 - d^2\Phi/dr^2} \right)^{1/3}, \tag{12.198}$$

where ω is the orbital angular velocity of the satellite, and $\Phi(r)$ is the gravitational potential due to the host.

12.44. Satellite Tidal Heating

The method to be used for computing the integrated, normalized (i.e. the energy divided by radius squared) tidal heating energy, $Q_{\rm tidal}$, for subhalos is specified by the `satelliteTidalHeatingMethod` parameter.

12.44.1. Null

Selected with `satelliteTidalHeatingMethod=null`, this method assumes that there is no tidal heating.

12.44.2. Gnedin (1999)

Selected by default with `satelliteTidalHeatingMethod=Gnedin1999`, this method uses the formalism of Gnedin et al. [1999] to compute the heating rate:

$$\dot{Q}_{\rm tidal} = \frac{1}{3}\epsilon \left[1 + \left(\frac{T_{\rm shock}}{T_{\rm orb}} \right)^2 \right]^{-\gamma} g_{ij} G^{ij} \tag{12.199}$$

where $T_{\rm orb}$ and $T_{\rm shock}$ are the orbital period and shock duration, respectively, of the satellite, $\epsilon =$ `[satelliteTidalHeatingGne` and $\gamma =$ `[satelliteTidalHeatingGnedinGamma]` are model parameters, g_{ij} is the tidal tensor, and G_{ij} is the integral with respect to time of g_{ij} along the orbit of the satellite. Upon tidal heating, a mass element at radius $r_{\rm i}$ expands to radius $r_{\rm f}$, according to the equation

$$\frac{1}{r_{\rm f}} = \frac{1}{r_{\rm i}} - \frac{2r_{\rm i}^3 Q_{\rm tidal}}{{\rm G}M_{\rm sat}(< r_{\rm i})}. \tag{12.200}$$

12.45. Star Formation Rate Surface Densities

The method for computing surface densities of star formation rate in disks is selected via `starFormationRateSurfaceDensityI`

12.45.1. Kennicutt-Schmidt

Selected with `starFormationRateSurfaceDensityDisksMethod=Kennicutt-Schmidt` this method assumes that the Kennicutt-Schmidt law holds [Schmidt, 1959, Kennicutt, 1998]:

$$\dot{\Sigma}_\star = A \left(\frac{\Sigma_{\rm H}}{M_\odot {\rm pc}^{-2}} \right)^N, \tag{12.201}$$

where $A =$ `[starFormationKennicuttSchmidtNormalization]` and $N =$ `[starFormationKennicuttSchmidtExponent]` are parameters. Optionally, if the `[starFormationKennicuttSchmidtTruncate]` parameter is set to true, then the star formation rate is truncated below a critical surface density such that

$$\dot{\Sigma}_\star = \begin{cases} A \left(\frac{\Sigma_{\rm H}}{M_\odot {\rm pc}^{-2}} \right)^N & \text{if } \Sigma_{\rm gas,disk} > \Sigma_{\rm crit} \\ A \left(\frac{\Sigma_{\rm H}}{M_\odot {\rm pc}^{-2}} \right)^N (\Sigma_{\rm gas,disk}/\Sigma_{\rm crit})^\alpha & \text{otherwise.} \end{cases} \tag{12.202}$$

Here, $\alpha =$ `[starFormationKennicuttSchmidtExponentTruncated]` and $\Sigma_{\rm crit}$ is a critical surface density for star formation which we specify as

$$\Sigma_{\rm crit} = \frac{q_{\rm crit} \kappa \sigma_{\rm gas}}{\pi {\rm G}}, \tag{12.203}$$

where κ is the epicyclic frequency in the disk, $\sigma_{\rm gas}$ is the velocity dispersion of gas in the disk and $q_{\rm crit} =$ `[toomreParameterCritical]` is a dimensionless constant of order unity which controls where the critical density occurs. We assume that $\sigma_{\rm gas}$ is a constant equal to `[velocityDispersionDiskGas]` and that the disk has a flat rotation curve such that $\kappa = \sqrt{2} V/R$.

12.45.2. Extended Schmidt

Selected with `starFormationRateSurfaceDensityDisksMethod=extendedSchmidt` this method assumes that the extended Schmidt law holds [Shi et al., 2011]:

$$\dot{\Sigma}_\star = A \left(x_{\rm H} \frac{\Sigma_{\rm gas}}{M_\odot {\rm pc}^{-2}} \right)^{N_1} \left(\frac{\Sigma_\star}{M_\odot {\rm pc}^{-2}} \right)^{N_2} \tag{12.204}$$

where $A =$ `[starFormationExtendedSchmidtNormalization]`, $N_1 =$ `[starFormationExtendedSchmidtGasExponent]` and $N_2 =$ `[starFormationExtendedSchmidtStarExponent]` are parameters.

12.45.3. Blitz-Rosolowsky

Selected with `starFormationRateSurfaceDensityDisksMethod=Blitz-Rosolowsky2006` this method assumes that the star formation rate is given by [Blitz and Rosolowsky, 2006]:

$$\dot{\Sigma}_\star(R) = \nu_{\rm SF}(R) \Sigma_{\rm H_2,disk}(R), \tag{12.205}$$

where $\nu_{\rm SF}$ is a frequency given by

$$\nu_{\rm SF}(R) = \nu_{\rm SF,0} \left[1 + \left(\frac{\Sigma_{\rm HI}}{\Sigma_0} \right)^q \right], \tag{12.206}$$

where $q =$ `[surfaceDensityExponentBlitzRosolowsky]` and $\Sigma_0 =$ `[surfaceDensityCriticalBlitzRosolowsky]` are parameters and the surface density of molecular gas $\Sigma_{\rm H_2} = (P_{\rm ext}/P_0)^\alpha \Sigma_{\rm HI}$, where $\alpha =$ `[pressureExponentBlitzRosolowsk` and $P_0 =$ `[pressureCharacteristicBlitzRosolowsky]` are parameters and the hydrostatic pressure in the disk plane assuming location isothermal gas and stellar components is given by

$$P_{\rm ext} \approx \frac{\pi}{2} {\rm G} \Sigma_{\rm gas} \left[\Sigma_{\rm gas} + \left(\frac{\sigma_{\rm gas}}{\sigma_\star} \right) \Sigma_\star \right] \tag{12.207}$$

where we assume that the velocity dispersion in the gas is fixed at $\sigma_{\rm gas} =$ `[velocityDispersionDiskGas]` and, assuming $\Sigma_\star \gg \Sigma_{\rm gas}$, we can write the stellar velocity dispersion in terms of the disk scale height, $h_\star$, as

$$\sigma_\star = \sqrt{\pi {\rm G} h_\star \Sigma_\star} \tag{12.208}$$

where we assume $h_\star / R_{\rm disk} =$ `[heightToRadialScaleDiskBlitzRosolowsky]`.

12.45.4. Krumholz-McKee-Tumlinson

Selected with `starFormationRateSurfaceDensityDisksMethod=KMT09` this method assumes that the star formation rate is given by [Krumholz et al., 2009]:

$$\dot{\Sigma}_\star(R) = \nu_{\rm SF} f_{\rm H_2}(R) \Sigma_{\rm HI,disk}(R) \left\{ \begin{array}{ll} (\Sigma_{\rm HI}/\Sigma_0)^{-1/3}, & \mathrm{if}\ \Sigma_{\rm HI}/\Sigma_0 \leq 1 \\ (\Sigma_{\rm HI}/\Sigma_0)^{1/3}, & \mathrm{if}\ \Sigma_{\rm HI}/\Sigma_0 > 1 \end{array} \right. , \tag{12.209}$$

where $\nu_{\rm SF}$ =`[starFormationFrequencyKMT09]` is a frequency and $\Sigma_0 = 85 M_\odot {\rm pc}^{-2}$. The molecular fraction is given by

$$f_{\rm H_2} = 1 - \left(1 + \left[\frac{3s}{4(1+\delta)} \right]^{-5} \right)^{-1/5} , \tag{12.210}$$

where

$$\delta = 0.0712 \left[0.1 s^{-1} + 0.675 \right]^{-2.8} , \tag{12.211}$$

and

$$s = \frac{\ln(1 + 0.6\chi + 0.01\chi^2)}{0.04 \Sigma_{\rm comp,0} Z'}, \tag{12.212}$$

with

$$\chi = 0.77 \left[1 + 3.1 Z'^{0.365} \right] , \tag{12.213}$$

and $\Sigma_{\rm comp,0} = c \Sigma_{\rm HI} / M_\odot {\rm pc}^{-2}$ where c =`[molecularComplexClumpingFactorKMT09]` is a density enhancement factor relating the surface density of molecular complexes to the gas density on larger scales. Alternatively, if `[molecularFractionFastKMT09]` is set to true, the molecular fraction will be computed using the faster (but less acccurate at low molecular fraction) formula

$$f_{\rm H_2} = 1 - \frac{3s/4}{(1 + s/4)}. \tag{12.214}$$

12.46. Star Formation Timescales

The methods for computing star formation timescales in disks and spheroids are selected via the `starFormationTimescaleDisk` and `starFormationTimescaleSpheroidsMethod` respectively.

12.46.1. Fixed

Selected with `starFormationTimescaleDisksMethod=fixed` this method assumes a fixed timescale for star formation `[starFormationTimescaleDisksFixedTimescale]` (in Gyr).

12.46.2. Halo Scaling

Selected with `starFormationTimescaleDisksMethod=haloScaling` this method assumes a timescale for star formation of

$$\tau_\star = \tau_{\star,0} \left(\frac{V_{\rm vir}}{200 {\rm km/s}} \right)^{\alpha_\star} (1+z)^{\beta_\star}, \tag{12.215}$$

where $\tau_{\star,0}$ =`[starFormationTimescaleDisksHaloScalingTimescale]`, $\alpha_\star$ =`[starFormationTimescaleDisksHaloScaling` and $\beta_\star$ =`[starFormationTimescaleDisksHaloScalingRedshiftExponent]`.

12.46.3. Dynamical Time

Selected with `starFormationTimescale[Disks|Spheroids]Method=dynamicalTime` this method computes the star formation timescale to be:

$$\tau_\star = \epsilon_\star^{-1} \tau_{\rm dynamical} \left(\frac{V}{200{\rm km/s}} \right)^{\alpha_\star}, \tag{12.216}$$

where $\epsilon_\star =$`starFormation[Disks|Spheroids]Efficiency` and $\alpha_\star =$`starFormation[Disks|Spheroids]VelocityExponent` are input parameters, $\tau_{\rm dynamical} \equiv r/V$ is the dynamical timescale of the component and r and V are the characteristic radius and velocity respectively of the component. The timescale is not allowed to fall below a minimum value specified by `starFormation[Disks|Spheroids]MinimumTimescale` (in Gyr).

12.46.4. Integrated Surface Density

Selected with `starFormationTimescaleDisksMethod=integratedSurfaceDensity` this method computes the star formation timescale to be:

$$\tau_\star = \frac{M_{\rm cold}}{\int_0^\infty 2\pi r \dot{\Sigma}_\star(r) {\rm d}r}, \tag{12.217}$$

where $\dot{\Sigma}_\star(r)$ is the surface density of star formation rate (see §12.45).

12.46.5. Baugh et al. (2005)

Selected with `starFormationTimescaleDisksMethod=Baugh2005` this method assumes that the star formation rate is given by a modified version of the Baugh et al. [2005] prescription:

$$\tau_\star = \tau_0 (V_{\rm disk}/200{\rm km/s})^\alpha a^\beta \tag{12.218}$$

where $\tau_0 =$`[starFormationDiskTimescale]`, $\alpha =$`[starFormationDiskVelocityExponent]` and $\beta =$`[starFormationExpans`

12.47. Stellar Population Properties

Algorithms for determining stellar population properties—essentially the rates of change of stellar and gas mass and abundances given a star formation rate and fuel abundances (and perhaps a historical record of star formation in the component)—are selected by the `stellarPopulationPropertiesMethod` parameter.

12.47.1. Instantaneous

Selected with `stellarPopulationPropertiesMethod=instantaneous` this method uses the instantaneous recycling approximation. Specifically, given a star formation rate ϕ, this method assumes a rate of increase of stellar mass of $\dot{M}_\star = (1-R)\phi$, a corresponding rate of decrease in fuel mass. The rate of change of the metal content of stars follows from the fuel metallicity, while that of the fuel changes according to

$$\dot{M}_{fuel,Z} = -(1-R) Z_{\rm fuel} \phi + p\phi. \tag{12.219}$$

In the above R is the instantaneous recycled fraction and p is the yield, both of which are supplied by the IMF subsystem. The rate of energy input from the stellar population is computed assuming that the canonical amount of energy from a single stellar population (as defined by the `feedbackEnergyInputAtInfinityCanonical`) is input instantaneously.

12.47.2. Noninstantaneous

Selected with `stellarPopulationPropertiesMethod=noninstantaneous` this method assumes fully non-instantaneous recycling and metal enrichment. Recycling and metal production rates from simple stellar populations are computed, for any given IMF, from stellar evolution models. The rates of change are then:

$$\dot{M}_\star = \phi - \int_0^t \phi(t')\dot{R}(t-t';Z_{\rm fuel}[t'])\mathrm{d}t', \tag{12.220}$$

$$\dot{M}_{\rm fuel} = -\phi + \int_0^t \phi(t')\dot{R}(t-t';Z_{\rm fuel}[t])\mathrm{d}t', \tag{12.221}$$

$$\dot{M}_{\star,Z} = Z_{\rm fuel}\phi - \int_0^t \phi(t')Z_{\rm fuel}(t')\dot{R}(t-t';Z_{\rm fuel}[t'])\mathrm{d}t', \tag{12.222}$$

$$\dot{M}_{{\rm fuel},Z} = -Z_{\rm fuel}\phi + \int_0^t \phi(t')\{Z_{\rm fuel}(t')\dot{R}(t-t';Z_{\rm fuel}[t']) + \dot{p}(t-t';Z_{\rm fuel}[t'])\}\mathrm{d}t', \tag{12.223}$$

$$\tag{12.224}$$

where $\dot{R}(t;Z)$ and $\dot{p}(t;Z)$ are the recycling and metal yield rates respectively from a stellar population of age t and metallicity Z. The energy input rate is computed self-consistently from the star formation history.

12.48. Stellar Population Spectra

Stellar population spectra are used to construct intgrated spectra of galaxies. The method used to compute such spectra is specified by the `stellarPopulationSpectraMethod` parameter.

12.48.1. Conroy, White & Gunn (2009)

Selected with `stellarPopulationSpectraMethod=Conroy-White-Gunn2009` this method uses v2.2 of the FSPS code of Conroy et al. [2009] to compute stellar spectra. If necessary, the FSPS code will be downloaded, patched and compiled and run to generate spectra. These tabulations are then stored to file for later retrieval. The file name used is `datasets/dynamic/stellarPopulations/simpleStellarPopulationsFSPS:v2.5_-<descriptor>.hdf5` where `<descriptor>` is an MD5 hash descriptor of the selected stellar population.

12.48.2. File

Selected with `stellarPopulationSpectraMethod=file` this method reads stellar population spectra from an HDF5 file, with format described in §16.4.1.

12.49. Stellar Population Spectra Postprocessing

Stellar population spectra are postprocessed (to handle, for example, absorption by the IGM).

Different chains of postprocessing methods can be applied to different filters. The `[luminosityPostprocessSet]` parameter specifies, for each filter, which chain of postprocessing filters to use. (If this parameter is not present then "`default`" is assumed for all filters.) The filters used in each chain are specified by the input parameter `[stellarPopulationSpectraPostprocess<setName>Method]` where `<setName>` is the name specified in `[luminosityPostprocessSet]`.

12.49.1. Inoue, Shimizu & Iwata (2014) IGM Attenuation

Selected with `stellarPopulationSpectraPostprocess<setName>Method=inoue2014` this method post-processes spectra through absorption by the IGM using the results of Inoue et al. [2014].

12.49.2. Meiksin (2006) IGM Attenuation

Selected with `stellarPopulationSpectraPostprocess<setName>Method=meiksin2006` this method post-processes spectra through absorption by the IGM using the results of Meiksin [2006].

12.49.3. Madau (1995) IGM Attenuation

Selected with `stellarPopulationSpectraPostprocess<setName>Method=madau1995` this method post-processes spectra through absorption by the IGM using the results of Madau [1995].

12.49.4. Lyman-continuum Suppression

Selected with `stellarPopulationSpectraPostprocess<setName>Method=lycSuppress` this method suppresses all emission in the Lyman continuum.

12.49.5. Recent Star Formation

Selected with `stellarPopulationSpectraPostprocess<setName>Method=recent` this method suppresses all emission from populations older than `[recentPopulationsTimeLimit]`.

12.49.6. Identity

Selected with `stellarPopulationSpectraPostprocess<setName>Method=identity` this method leaves the spectrum unchanged.

12.50. Stellar Astrophysics

Various properties related to stellar astrophysics are required by Galacticus. The following documents their implementation.

12.50.1. Basics

This subset of properties include recycled mass, metal yield and lifetime. The method used to compute such properties is specified by the `stellarAstrophysicsMethod` parameter.

File

Selected with `stellarAstrophysicsMethod=file` this method uses reads properties of individual stars of different initial mass and metallicity from an XML file and interpolates in them. The stars can be irregularly spaced in the plane of initial mass and metallicity. The XML file should have the following structure:

```
<stars>
 <star>
   <initialMass>0.6</initialMass>
   <lifetime>28.19</lifetime>
```

```
    <metallicity>0.0000</metallicity>
    <ejectedMass>7.65</ejectedMass>
    <metalYieldMass>0.44435954</metalYieldMass>
    <elementYieldMassFe>2.2017e-13</elementYieldMassFe>

  .
 </stars
```

Each `star` element must contain the `initialMass` (given in $M_\odot$) and `metallicity` tags. Other tags are optional. `lifetime` gives the lifetime of such a star (in Gyr), `ejectedMass` gives the total mass (in $M_\odot$) ejected by such a star during its lifetime, `metalYieldMass` gives the total mass of metals yielded by the star during its lifetime while `elementYieldMassX` gives the mass of element `X` yielded by the star during its lifetime. The `source` and `url` tags are not used, but are strongly recommended to provide a reference to the origin of the stellar data.

12.50.2. Stellar Winds

Energy input to the ISM from stellar winds is used in calculations of feedback efficiency. The method used to compute stellar wind properties is specified by the `stellarWindsMethod` parameter.

Leitherer et al. (1992)

Selected with `stellarWindsMethod=Leitherer1992` this method uses the fitting formulae of Leitherer et al. [1992] to compute stellar wind energy input from the luminosity and effective temperature of a star.

12.50.3. Stellar Tracks

The method used to compute stellar tracks is specified by the `stellarTracksMethod` parameter.

File

Selected with `stellarTracksMethod=file` in this method luminosities and effective temperatures of stars are computed from a tabulated set of stellar tracks. The file containing the tracks to use is specified via the `stellarTracksFile` parameter. The file specified must be an HDF5 file with the following structure:

```
stellarTracksFile
 |
 +-> metallicity1
 |    |
 |    +-> metallicity
 |    |
```

```
|    +-> mass1
|    |    |
|    |    +-> mass
|    |    |
|    |    +-> age
|    |    |
|    |    +-> luminosity
|    |    |
|    |    +-> effectiveTemperature
|    |
|    x-> massN
|
x-> metallicityN
```

Each `metallicityN` group tabulates tracks for a given metallicity (the value of which is stored in the `metallicity` dataset within each group), and may contain an arbitrary number of `massN` groups. Each `massN` group should contain a track for a star of some mass (the value of which is given in the `mass` dataset). Within each track three datasets specify the `age` (in Gyr), `luminosity` (in $L_\odot$) and `effectiveTemperature` (in Kelvin) along the track.

12.50.4. Supernovae Type Ia

Properties of Type Ia supernovae, including the cumulative number occuring and metal yield, are handled by the method selected using the `supernovaeIaMethod` parameter.

Nagashima et al. (2005) Prescription

Selected with `supernovaeIaMethod`=`Nagashima` this method uses the prescriptions from Nagashima et al. [2005] to compute the numbers and yields of Type Ia supernovae.

12.50.5. Population III Supernovae

Properties of Population III specific supernovae are handled by the method selected with the `supernovaePopIIIMethod` parameter.

Heger & Woosley (2002)

Selected with `supernovaePopIIIMethod`=`Heger-Woosley2002` this method computes the energies of pair instability supernovae from the results of Heger and Woosley [2002].

12.50.6. Stellar Feedback

Aspects of stellar feedback are computed by the method selected with the `stellarFeedbackMethod` parameter.

Standard

Selected with `stellarFeedbackMethod`=`standard`, the method assumes that the cumulative energy input from a stellar population is equal to the total number of (Type II and Type Ia) supernovae multiplied by `supernovaEnergy` (specified in ergs) plus any Population III-specific supernovae energy plus the integrated energy input from stellar winds. The minimum mass of a star required to form a Type II supernova is specified (in $M_\odot$) via the `initialMassForSupernovaeTypeII` parameter.

12.51. Substructure and Merging

Substructures and merging of nodes/substructures is controlled by several algorithms which are described below:

12.51.1. Merging Timescales

The method used to compute merging timescales of substructures is specified by the `satelliteMergingTimescalesMethod` parameter.

Lacey & Cole (1993)

Selected with `satelliteMergingTimescalesMethod=laceyCole1993`, this method computes merging timescales using the dynamical friction calculation of Lacey and Cole [1993]. Timescales are multiplied by the value of the `mergingTimescaleMultiplier` input parameter.

Lacey & Cole (1993) + Tormen

Selected with `satelliteMergingTimescalesMethod=laceyCole1993Tormen`, this method computes merging timescales using the dynamical friction calculation of Lacey and Cole [1993] with a parameterization of orbital parameters designed to fit the results of Tormen [1997] as described by Cole et al. [2000]. Timescales are multiplied by the value of the `mergingTimescaleMultiplier` input parameter. Specifically, the merging time is taken to be:

$$\tau_\mathrm{merge} = \frac{f_\tau \Phi \tau_\mathrm{dynamical}}{2B(1)} \frac{M_\mathrm{host}/M_\mathrm{satellite}}{\ln(M_\mathrm{host}/M_\mathrm{satellite})} \tag{12.225}$$

where $f_\tau =$`mergingTimescaleMultiplier`, $\tau_\mathrm{dynamical}$ is the dynamical time of the host halo and $B(x) = \mathrm{erf}(x) - 2x\exp(x)/\sqrt{\Pi}$. The orbital factor $\Phi \equiv \epsilon^{0.78}(R_\mathrm{c}/R_\mathrm{virial})^2$ is drawn at random from a log-normal distribution with median -0.14 and dispersion 0.26 as found by Cole et al. [2000].

Jiang (2008)

Selected with `satelliteMergingTimescalesMethod=jiang2008`, this method computes merging timescales using the dynamical friction calibration of Jiang et al. [2008]. Jiang et al. [2008] find that their fitting formula does not perfectly capture the results of N-body simulations, instead showing a scatter in the ratio $T_\mathrm{fit}/T_\mathrm{sim}$ where T_fit is the merging time from their fitting formula and T_sim is that measured from their N-body simulation. Furthermore, they show that the distribution of $T_\mathrm{fit}/T_\mathrm{sim}$ is well described by a log-normal with dispersion (in $\log[T_\mathrm{fit}/T_\mathrm{sim}]$) of $\sigma = 0.4$. Random perturbations can be applied to the merger times returned by this implementation by setting $\sigma =$`[satelliteMergingJiang2008Scatter]` > 0 which will cause the merger time to be drawn from a log-normal distribution of width σ with median equal to T_fit.

Boylan-Kolchin (2008)

Selected with `satelliteMergingTimescalesMethod=boylanKolchin2008`, this method computes merging timescales using the dynamical friction calibration of Boylan-Kolchin et al. [2008].

Wetzel & White (2010)

Selected with `satelliteMergingTimescalesMethod=wetzelWhite2010`, this method computes merging timescales using the dynamical friction calibration of Wetzel and White [2010].

Villalobos et al. (2013)

Selected with `satelliteMergingTimescalesMethod=villalobos2013`, this method computes merging timescales using the modifier of Villalobos et al. [2013] as

$$\tau_{\rm merge} = (1+z)^{\alpha}\tau'_{\rm merge}, \tag{12.226}$$

where $\alpha =$ `[satelliteMergingTimescaleVillalobos2013Exponent]` and $\tau'_{\rm merge}$ is the merging timescale computed by another satellite merging timescale method as specified via `[satelliteMergingTimescaleVillalobos2013Base`

Preset

Selected with `satelliteMergingTimescalesMethod=preset`, this method returns a precomputed merging timescale stored by the satellite component.

Null

Selected with `satelliteMergingTimescalesMethod=null`, this method returns zero merging timescale.

Infinite

Selected with `satelliteMergingTimescalesMethod=infinite`, this method returns an infinite merging timescale (technically, it returns 10^{30} Gyr which should be sufficiently close to infinity for practical purposes).

12.51.2. Virial Orbits

The algorithm to be used to determine orbital parameters of substructures when they first enter the virial radius of their host is specified via the `virialOrbitMethod` parameter.

Benson (2005)

Selected with `virialOrbitMethod=benson2005`, this method selects orbital parameters randomly from the distribution given by Benson [2005]. If the virial density contrast definition differs from that used by Benson [2005] then the orbit is assigned based on Benson [2005]'s definition and then propagated to the virial radius relevant to the current definition of density contrast.

Fixed

Selected with `virialOrbitMethod=fixed`, this method sets all orbital parameters to fixed values, with $v_{\rm r} =$ `[virialOrbitsFixedRadialVelocity]` $V_{\rm virial}$ and $v_\phi =$ `[virialOrbitsFixedTangentialVelocity]` $V_{\rm virial}$.

Wetzel (2010)

Selected with `virialOrbitMethod=wetzel2010`, this method selects orbital parameters randomly from the distribution given by Wetzel [2010], including the redshift and mass dependence of the distributions. Note that the parameter R_1 can become negative (which is unphysical) for certain regimes of mass and redshift according to the fitting function for R_1 given by Wetzel [2010]. Therefore, we enforce $R_1 > 0.05$. Similarly, the parameter C_1 can become very large in some regimes which is probably an artifact of the fitting function used rather than physically meaningful (and which causes numerical difficulties in evaluating the distribution). We therefore prevent C_1 from exceeding 9.999999[11] If the virial density

[11] We use this value rather than 10 since the GSL ${}_2F_1$ hypergeomtric function fails in some cases when $C_1 \geq 10$.

contrast definition differs from that used by Wetzel [2010] then the orbit is assigned based on Wetzel [2010]'s definition and then propagated to the virial radius relevant to the current definition of density contrast.

Jiang et al. (2014)

Selected with `virialOrbitMethod=jiang2014`, this method selects orbital parameters randomly from the distribution given by Jiang et al. [2014], including the mass and mass-ratio dependence of the distributions. If the virial density contrast definition differs from that used by Jiang et al. [2014] then the orbit is assigned based on Jiang et al. [2014]'s definition and then propagated to the virial radius relevant to the current definition of density contrast.

12.51.3. Node Merging

The algorithm to be used to process nodes when they become substructures is specified by the `nodeMergersMethod` parameter.

Single Level Hierarchy

Selcted with `nodeMergersMethod=singleLevelHierarchy`, this method maintains a single level hierarchy of substructure, i.e. it tracks only substructures, not sub-substructures or deeper levels. When a node first becomes a satellite it is appended to the list of satellites associated with its host halo. If the node contains its own satellites they will be detached from the node and appended to the list of satellites of the new host (and assigned new merging times).

12.52. Supernovae Feedback Models

The supernovae feedback driven outflow rate is computed using the method specified by the `starFormationFeedback[Disks|S` for disks and spheroids respectively.

12.52.1. Fixed

Selected with `starFormationFeedbackDisksMethod=fixed`, this method assumes an outflow rate of:

$$\dot{M}_{\rm outflow} = f_{\rm outflow} \frac{\dot{E}}{E_{\rm canonical}}, \tag{12.227}$$

where $f_{\rm outflow}$ =`[diskOutflowFraction]` is the fraction of the star formation rate that goes into outflow, $\dot{E}$ is the rate of energy input from stellar populations and $E_{\rm canonical}$ is the total energy input by a canonical stellar population normalized to $1 M_\odot$ after infinite time.

12.52.2. Power Law

Selected with `starFormationFeedback[Disks|Spheroids]Method=powerLaw`, this method assumes an outflow rate of:

$$\dot{M}_{\rm outflow} = \left(\frac{V_{\rm outflow}}{V} \right)^{\alpha_{\rm outflow}} \frac{\dot{E}}{E_{\rm canonical}}, \tag{12.228}$$

where $V_{\rm outflow}$ =`[disk|spheroid]OutflowVelocity` (in km/s) and $\alpha_{\rm outflow}$ =`[disk|spheroid]OutflowVelocity` are input parameters, V is the characteristic velocity of the component, $\dot{E}$ is the rate of energy input from stellar populations and $E_{\rm canonical}$ is the total energy input by a canonical stellar population normalized to $1 M_\odot$ after infinite time.

12.52.3. Creasey et al. (2012)

Selected with `starFormationFeedbackDisksMethod=Creasey2012`, this method computes the outflow rate using the model of Creasey et al. [2012]. Specifically,

$$\dot{M}_{\rm outflow} = \frac{\dot{E}_{\rm SN}}{E_{\rm SN}\dot{M}_\star}\int_0^\infty \beta_0 \Sigma_{g,1}^{-\mu}(r) f_{\rm g}^{\nu}(r)\dot{\Sigma}_\star(r) 2\pi r {\rm d}r, \tag{12.229}$$

where $\Sigma_{g,1}(r)$ is the surface density of gas in units of $M_\odot$ pc^{-2}, $f_{\rm g}(r)$ is the gas fraction, $\dot{\Sigma}_\star(r)$ is the surface density of star formation rate, $\dot{M}_\star$ is the total star formation rate in the disk, $\dot{E}_{\rm SN}$ is the current energy input rate from supernovae, $E_{\rm SN}$ is the total energy input per unit mass from a stellar population after infinite time, $\beta_0 =$`[starFormationFeedbackDisksCreasy2012Beta0]`, $\mu =$`[starFormationFeedbackDisksCreasy2012Mu]`, and $\nu =$`[starFormationFeedbackDisksCreasy2012Nu]`.

12.53. Supernovae Expulsive Feedback Models

The expulsive supernovae feedback driven outflow rate is computed using the method specified by the `starFormationExpulsiveFeedback[Disks|Spheroids]Method` for disks and spheroids respectively.

12.53.1. Null

Selected with `starFormationExpulsiveFeedback[Disks|Spheroids]Method=null`, this method assumes a zero outflow rate.

12.53.2. Superwind

Selected with `starFormationExpulsiveFeedback[Disks|Spheroids]Method=superwind`, this method assumes an outflow rate of:

$$\dot{M}_{\rm outflow} = \beta_{\rm superwind}\frac{\dot{E}}{E_{\rm canonical}}\begin{cases}(V_{\rm superwind}/V)^2 & \text{if } V > V_{\rm superwind} \\ 1 & \text{otherwise,}\end{cases} \tag{12.230}$$

where $V_{\rm superwind} =$`[disk|spheroid]SuperwindVelocity` (in km/s) and $\beta_{\rm superwind} =$`[disk|spheroid]SuperwindMassLoadin` are input parameters, V is the characteristic velocity of the component, $\dot{E}$ is the rate of energy input from stellar populations and $E_{\rm canonical}$ is the total energy input by a canonical stellar population normalized to $1M_\odot$ after infinite time.

12.54. Supermassive Black Hole Binaries: Initial Separation

The method to be used for computing the initial separation of black hole binaries is specified by the `blackHoleBinaryInitialRadiiMethod` parameter.

12.54.1. Spheroid Radius Fraction

Selected with `blackHoleBinaryInitialRadiiMethod=spheroidRadiusFraction`, this method assumes that the initial separation of the binary is equal to a fixed fraction `[blackHoleInitialRadiusSpheroidRadiusRatio]` of the larger of the spheroid scale radii of the two merging galaxies.

12.54.2. Volonteri (2003)

Selected with `blackHoleBinaryInitialRadiiMethod=Volonteri2003`, this method assumes that the initial separation follows the relationship described in Volonteri et al. [2003]

$$r_{\rm initial} = \frac{\rm G(M_{\bullet,1} + M_{\bullet,2})}{2\sigma^2_{\rm DM}} \tag{12.231}$$

where $M_{\bullet,1}$ and $M_{\bullet,2}$ are the masses of the black holes and $\sigma_{\rm DM}$ is the velocity dispersion of the dark matter, which we assume to equal the virial velocity of the dark matter halo.

12.54.3. Tidal Radius

Selected with `blackHoleBinaryInitialRadiiMethod=tidalRadius`, this method assumes an initial separation that corresponds to the distance at which the satellite galaxy is tidally stripped to its half-mass radius, thus only leaving the central massive black hole. Specifically, the initial radius is given by:

$$\frac{M_{\rm sat}}{2r^3_{\rm sat,1/2}} = -\frac{\rm d}{{\rm d}r}\frac{M_{\rm host}(r_{\rm initial})}{r^2_{\rm initial}} \tag{12.232}$$

Where $M_{\rm sat}$ is the mass of the satellite galaxy, $r_{\rm sat,1/2}$ is its half mass radius, $M_{\rm host}(r)$ is the mass of the host galaxy within radius r and $r_{\rm initial}$ is the initial radius.

12.55. Supermassive Black Hole Binaries: Separation Growth Rate

The method to be used for computing the separation growth rate of black hole binaries is specified by the `blackHoleBinarySeparationGrowthRateMethod` parameter.

12.55.1. Null

Selected by default and with `blackHoleBinarySeparationGrowthRateMethod=null`, this method assumes that the initial separation of the binaries is final.

12.55.2. Standard

Selected with `blackHoleBinarySeparationGrowthRateMethod=Standard`, this method computes the separation growth rate of the binaries following a modified version of Volonteri et al. [2003] which include terms for dynamical friction, hardening due to scattering of stars and gravitational wave emission.

$$\dot{a} = \min\left(-\frac{\rm G\rho_* a^2 H}{\sigma}, +\frac{2\dot{v}_{\rm DF} a}{v_c}\right) - \frac{256 G^3 M_{\bullet,1} M_{\bullet,2}(M_{\bullet,1}+M_{\bullet,2})}{5c^5 a^3} \tag{12.233}$$

where a is the black hole binary separation, H is a dimensionless hardening parameter $H \approx 15$ in the limit of a very hard, equal mass binary, $\rho_\star$ is the density of stars, $\dot{v}_{\rm DF}$ is the acceleration (negative) due to dynamical friction, $v_{\rm c}$ is the circular velocity, σ is the velocity dispersion of stars. Here the first factor represents hardening due to strong scattering of stars, the second results from dynamical friction with distant stars, gas and dark matter and the last results from the emission of gravitational waves Peters [1964].

The acceleration due to dynamical friction is computed using Chandrasekhar's formula:

$$\dot{v}_{\rm DF} = -\frac{2\pi {\rm G}^2 M_\bullet}{V_{\rm C}^2} \sum_i \rho_i \log(1+\Lambda_i^2) \left[{\rm erf}(X_i) - \left\{ \frac{2X_i}{\sqrt{\pi}} \exp\left(-X_i^2\right) \right\} \right], \tag{12.234}$$

where the sum is taken over the spheroid (gaseous plus stellar mass) and dark matter halo components[12]. Here,

$$\Lambda_i = \frac{a\sigma^2}{{\rm G}(M_{\bullet,1}+M_{\bullet,2})}, \tag{12.235}$$

is the Coulomb logarithm and

$$X_i = V_{\rm c}/\sqrt{2}\sigma. \tag{12.236}$$

In all of the above equations, the velocity dispersion σ_i is computed from the spherical Jeans equation assuming an isotropic velocity dispersion if `[blackHoleBinariesComputeVelocityDispersion]=true`. Otherwise, σ_i is set to the halo virial velocity for dark matter and to the spheroid characteristic velocity for the spheroid.

In calculating the rate of hardening due to scattering of stars, the stellar density is reduced by a factor [Volonteri et al., 2003]

$$f_\rho = \min\left\{ \left[\frac{4a\sigma^2_{\rm spheroid}}{3{\rm G}(M_{\bullet,1}+M_{\bullet,2})} \log\left(\frac{{\rm G}M_{\bullet,2}}{4\sigma^2_{\rm spheroid}a} \right) \right]^2, 1 \right\}, \tag{12.237}$$

if `[stellarDensityChangeBinaryMotion]=true` to account for the ejection of stars from the loss cone.

12.56. Supermassive Black Holes Binaries: Recoil Velocity

The method to be used for computing the recoil velocity due to gravitaional waves ejection during a binary merger specified by the `blackHoleBinaryRecoilVelocityMethod` parameter.

12.56.1. Null

Selected by default and with `blackHoleBinaryRecoilVelocityMethod=null`, this method assumes that there is no recoil velocity.

12.56.2. Campanelli et al. (2007)

Selected with `blackHoleBinaryRecoilVelocityMethod=Campanelli2007`, this method computes the recoil velocity during a black hole binary merger due to the emission of gravitational waves, following the formulae derived in Campanelli et al. [2007]

$$V_{\rm recoil} = V_{\rm m}\hat{\mathbf{e_1}} + V_\perp(\cos\xi\hat{\mathbf{e_1}} + \sin\xi\hat{\mathbf{e_2}}) + V_\parallel\hat{\mathbf{e_2}} \tag{12.238}$$

with:

$$V_{\rm m} = A\frac{q^2(1-q)}{(1+q)^5}(1+B\frac{q}{(1+q)^2}) \tag{12.239}$$

$$V_\perp = H\frac{q^2}{(1+q)^5}(\alpha_2^\parallel - q\alpha_1^\parallel) \tag{12.240}$$

[12]The disk is ignored as the black hole is assumed to be orbitting in a circular orbit in the disk.

$$V_{\parallel} = K\cos(\theta - \theta_0)\frac{q^2}{(1+q)^5}(\alpha_2^{\perp} - q\alpha_1^{\perp}) \tag{12.241}$$

where θ is defined as the angle between the inplane component of Δ and the infall direction at merger. q is the mass ratio of the black holes as $q = M_{\bullet,1}/M_{\bullet,2}$ and $\alpha_i = \mathbf{S_i}/M_{\bullet,i}$ depends of the spin and mass of the black hole ξ measures the angle between the unequal mass and the spin contribution to the recoil velocity in the orbital plane. $\hat{\mathbf{e_1}}, \hat{\mathbf{e_2}}$ are orthogonal unit vectors in the orbital plane. Our method assumes the spin of the second black hole is randomly generated, while that of the first is aligned with the angular momentum of the system. The constants used are retrieved from the articles by: Koppitz et al. [2007] for $H = (7.3 \pm 0.3)10^3$ km/s, González et al. [2007b] for $A = 1.2 \times 10^4$ km/s $B = -0.93$, González et al. [2007a] for $K\cos(\delta\theta) = (6, -5.3)10^4$ km/s and $K = (6.0 \pm 0.1)10^4$ km/s.

12.57. Supermassive Black Hole Binaries: Mergers

The method to be used for computing the effects of binary mergers of supermassive black holes is specified by the `blackHoleBinaryMergersMethod` parameter.

12.57.1. Rezzolla et al. (2008)

Selected with `blackHoleBinaryMergersMethod=Rezzolla2008`, this method uses the fitting function of Rezzolla et al. [2008] to compute the spin of the black hole resulting from a binary merger. The mass of the resulting black hole is assumed to equal the sum of the mass of the initial black holes (i.e. there is negligible energy loss through gravitational waves).

12.58. Tidal Induced Mass Loss Rates in Disks/Spheroids

The methods for computing tidal induced rates of mass loss in disks/spheroids are selected via the `tidalStrippingMassLossRate(Disks|Spheroids)Method` parameter.

12.58.1. Simple

Selected with `tidalStrippingMassLossRate(Disks|Spheroids)Method=simple` this method computes the mass loss rate to be:

$$\dot{M} = -\alpha M/\tau_{(\mathrm{disk|spheroid}}, \tag{12.242}$$

where

$$\alpha = \min(F_{\mathrm{tidal}}/F_{\mathrm{gravity}}, R_{\mathrm{maximum}}), \tag{12.243}$$

$F_{\mathrm{tidal}} = \mathcal{F}_{\mathrm{tidal}} r_{1/2}$, $\mathcal{F}_{\mathrm{tidal}}$ is the tidal field from the host halo (see §12.42),

$$F_{\mathrm{gravity}} = V_{1/2}^2(r_{1/2})/r_{1/2} \tag{12.244}$$

is the gravitational restoring force in the disk/spheroid at the half-mass radius, $r_{1/2}$, and $R_{\mathrm{maximum}} =$ `[tidalStrippingMassLos`

12.58.2. Null

Selected with `tidalStrippingMassLossRate(Disks|Spheroids)Method=null` this method assumes zero mass loss rate always.

12.59. Survey Geometry

The method to be used for computing the geometry of surveys for data analysis is specified by the `surveyGeometryMethod` parameter.

12.59.1. Li & White (2009)

Selected with `surveyGeometryMethod=liWhite2009SDSS`, this method describes the survey geometry of Li and White [2009].

For the angular mask, we make use of the catalog of random points within the survey footprint provided by the NYU-VAGC[13] (Blanton et al. 2005; see also Adelman-McCarthy et al. 2008, Padmanabhan et al. 2008). Li and White [2009] consider only the main, contiguous region and so we keep only those points which satisfy RA$>$ 100°, RA$<$ 300°, and RA$<$ 247° or $\delta < 51°$. When the survey window function is needed, these points are used to determine which elements of a 3D grid fall within the window function.

To estimate the depth of the Li and White [2009] sample as a function of galaxy stellar mass we make use of semi-analytic models in the Millennium Database. Specifically, we use the SAM of De Lucia and Blaizot (2007; specifically the `millimil..DeLucia2006a` and `millimil..DeLucia2006a_sdss2mass` tables in the Millennium Database). For each snapshot in the database, we extract the stellar masses and observed-frame SDSS r-band absolute magnitudes (including dust extinction), and determine the median absolute magnitude as a function of stellar mass. Using the limiting apparent magnitude of the Li and White [2009] sample, $r = 17.6$, we infer the corresponding absolute magnitude at each redshift and, using our derived absolute magnitude–stellar mass relation, infer the corresponding stellar mass.

The end result of this procedure is the limiting stellar mass as a function of redshift, accounting for k-corrections, evolution, and the effects of dust. Figure 12.1 shows the resulting relation between stellar mass and the maximum redshift at which such a galaxy would be included in the sample. Points indicate measurements from the SAM, while the line shows a polynomial fit:

$$\begin{aligned} z(M_\star) &= -5.950 + 2.638m - 0.4211m^2 \\ &\quad +2.852 \times 10^{-2}m^3 - 6.783 \times 10^{-4}m^4, \end{aligned} \tag{12.245}$$

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass. We adopt a solid angle of 2.1901993 sr [Percival et al., 2007] for the sample.

12.59.2. Bernardi et al. (2013)

Selected with `surveyGeometryMethod=bernardi2013SDSS`, this method describes the survey geometry of Bernardi et al. [2013].

For the angular mask, we make use of the MANGLE polygon file provided by the MANGLE project[14] The solid angle of this mask, computed using the MANGLE `harmonize` command is 2.232262776405 sr.

To determine the depth as a function of stellar mass, we make use of results provided by M. Bernardi (private communication), giving the mean maximum volume, $V_{\rm max}$, as a function of stellar mass for galaxies in this sample. These maximum volumes are converted to maximum distances using the solid angle quoted above. The results mass vs. distance relation is fit with a 5$^{\rm th}$-order polynomial. Figure 12.2 shows the resulting relation between stellar mass and the maximum distance at which such a galaxy would be included in the sample. Points indicate results from Bernardi, while the line shows a polynomial fit:

$$\log_{10}\left[\frac{D_{\rm max}(M_\star)}{\rm Mpc}\right] = 1282.11+m(-626.644+m(122.091+m(-11.8431+m(0.572399+m(-0.0110301))))) \tag{12.246}$$

[13]Specifically, http://sdss.physics.nyu.edu/lss/dr72/random/lss_random-0.dr72.dat.
[14]Specifically, http://space.mit.edu/ molly/mangle/download/data/sdss_dr72safe0_res6d.pol.gz.

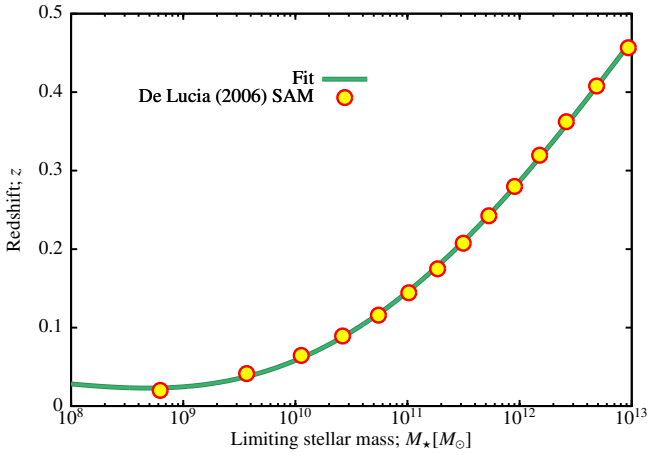

Figure 12.1.: The maximum redshift at which a galaxy of given stellar mass can be detected in the sample of Li and White [2009]. Points show the results obtained using the De Lucia and Blaizot [2007] model from the Millennium Database, while the lines shows a polynomial fit to these results (given in eqn. 12.245).

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

12.59.3. Davidzon et al. (2013)

Selected with `surveyGeometryMethod=davidzon2013VIPERS`, this method describes the survey geometry of Davidzon et al. [2013].

For the angular mask, we make use of `mangle` polygon files provided by I. Davidzon (private communication) corresponding to the VIPERS fields. The solid angle of each mask is computed using the `mangle harmonize` command.

To determine the depth as a function of stellar mass, we make use of the tabulated mass function, ϕ, and number of galaxies per bin, N, supplied by I. Davidzon (private communication). The effective volume of each bin is found as $V_i = N_i/f_{\rm complete}\phi_i\Delta\log_{10} M_\star$, where $\Delta\log_{10} M_\star$ is the width of the bin, and $f_{\rm complete}$ is the completeness of the survey, estimated to be approximately 40% [Guzzo et al., 2013]. These volumes are converted to maximum distances in each field using the survey solid angle. The resulting mass vs. distance relation in each field is fit with a 1$^{\rm st}$-order polynomial in log-log space over the range where the maximum volume is limited by the survey depth and not by the imposed upper limit to redshift. Figure 12.3 shows the resulting relation between stellar mass and the maximum distance at which such a galaxy would be included in the sample. Points indicate results from VIPERS, while the lines show polynomial fits:

$$\log_{10}\left[\frac{D_{\rm max}(M_\star)}{\rm Mpc}\right] = \begin{cases} 3.207 + 0.0124m & 0.5 < z < 0.6 \\ 3.148 + 0.0268m & 0.6 < z < 0.8 \\ 3.207 + 0.0273m & 0.8 < z < 1.0 \end{cases} \tag{12.247}$$

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

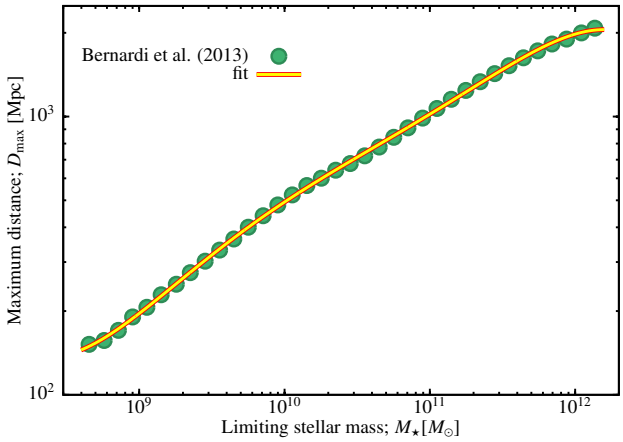

Figure 12.2.: The maximum distance at which a galaxy of given stellar mass can be detected in the sample of Bernardi et al. [2013]. Points show the results obtained from data provided by Bernardi, while the lines shows a polynomial fit to these results (given in eqn. 12.246).

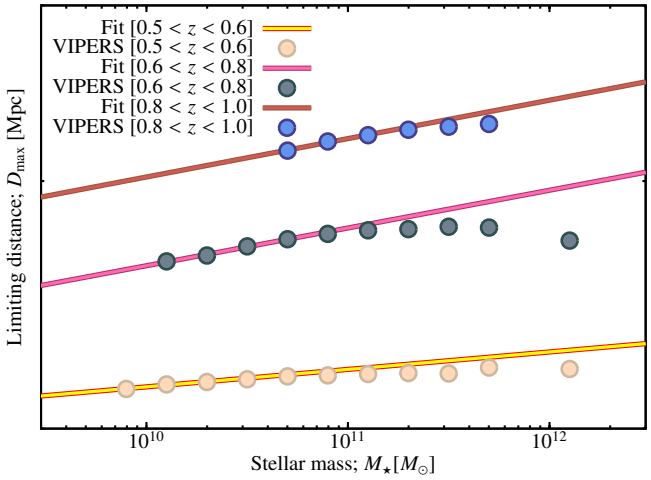

Figure 12.3.: The maximum distance at which a galaxy of given stellar mass can be detected in the sample of Davidzon et al. [2013]. Points show the results obtained from data provided by Davidzon, while the lines shows a polynomial fit to these results (given in eqn. 12.247). Note that at high masses the distance is limited by the imposed upper limit—the polynomial fit does not consider these points.

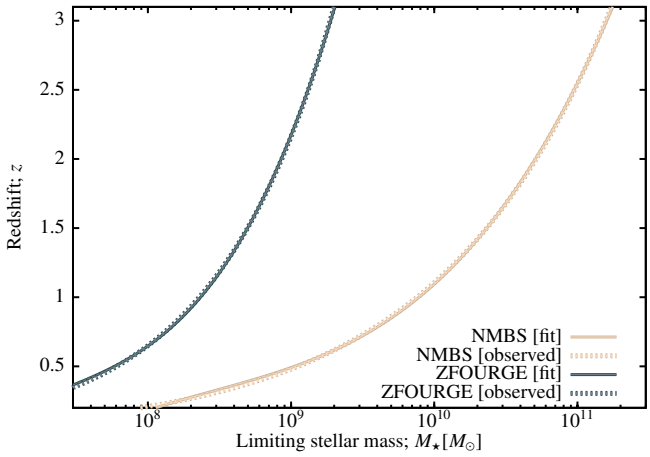

Figure 12.4.: The maximum redshift at which a galaxy of given stellar mass can be detected in the sample of Tomczak et al. [2014]. Points show the results obtained from data provided by Davidzon, while the lines shows a polynomial fit to these results (given in eqn. 12.248).

12.59.4. Tomczak et al. (2014)

Selected with `surveyGeometryMethod=tomczak2014ZFOURGE`, this method describes the survey geometry of Tomczak et al. [2014].

For the angular mask, we make use of `mangle` polygon files constructed by hand using vertices matched approximately to the distribution of galaxies in the survey (positions of which were provided by R. Quadri; private communication). The solid angle of each mask is computed using the `mangle harmonize` command.

To determine the depth as a function of stellar mass, we make use of the tabulated mass completeness limits as a function of redshift for ZFOURGE and NMBS fields provided by R. Quadri (private communication). These are fit with fourth-order polynomials. Figure 12.4 shows the resulting relation between stellar mass and the maximum redshift at which such a galaxy would be included in the sample. Dotted lines indicate the tabulated result from ZFOURGE, while the lines show polynomial fits:

$$z_{\max}(M_\star) = \begin{cases} -114.66 + m*(45.901 + m*(-6.1617 + m*(0.27822))) & \text{ZFOURGE fields} \\ -58.483 + m*(20.250 + m*(-2.3563 + m*(0.092705))) & \text{NMBS fields} \end{cases} \tag{12.248}$$

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

12.59.5. Baldry et al. (2012)

Selected with `surveyGeometryMethod=baldry2012GAMA`, this method describes the survey geometry of Baldry et al. [2012].

For the angular mask we use the specifications of the G09, G12, and G15 fields given by Driver et al. [2011] to construct MANGLE polygon files.

To determine the depth as a function of stellar mass, we make use of the publicly available tabulated mass function, ϕ, and number of galaxies per bin, N. The effective volume of each bin is found as $V_i = N_i/\phi_i \Delta \log_{10} M_\star$, where $\Delta \log_{10} M_\star$ is the width of the bin. The GAMA survey consists of three fields, each of the same solid angle, but with differing depths. We assume that the relative depths in

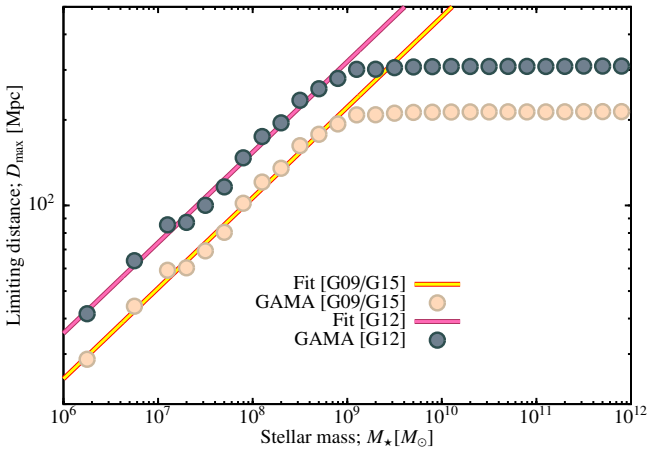

Figure 12.5.: The maximum distance at which a galaxy of given stellar mass can be detected in the sample of Baldry et al. [2012]. Points show the results obtained from data provided by Baldry, while the lines shows a polynomial fit to these results (given in eqn. 12.249). Note that above $10^9 M_\odot$ the distance is limited by the imposed upper limit of $z = 0.06$ in the GAMA sample—the polynomial fit does not consider these points.

terms of stellar mass scale with the depth in terms of flux. Given this assumption, these volumes are converted to maximum distances in each field using the solid angle quoted above. The resulting mass vs. distance relation in each field is fit with a 1$^{\rm st}$-order polynomial in log-log space over the range where the maximum volume is limited by the survey depth and not by the imposed $z = 0.06$ upper limit to redshift. Figure 12.5 shows the resulting relation between stellar mass and the maximum distance at which such a galaxy would be included in the sample. Points indicate results from GAMA, while the line shows a polynomial fit:

$$\log_{10}\left[\frac{D_{\rm max}(M_\star)}{\rm Mpc}\right] = \begin{cases} -0.521 + 0.319m & \text{fields G09/G15} \\ -0.361 + 0.319m & \text{field G12} \end{cases} \tag{12.249}$$

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

12.59.6. Moustakas et al. (2013)

Selected with `surveyGeometryMethod=moustakas2013PRIMUS`, this method describes the survey geometry of Moustakas et al. [2013].

For the angular mask, we make use of MANGLE polygon files provided by J. Moustakas (private communication) corresponding to the give PRIMUS fields. The solid angle of each mask is computed using the MANGLE `harmonize` command.

To determine the depth as a function of stellar mass, we make use of completeness limits for "All" galaxies given in Table 2 of Moustakas et al. [2013]. These are fit, for each field with a second order polynomial to give the limiting redshift as a function of stellar mass. Figure 12.6 shows the resulting relation between stellar mass and the maximum redshift at which such a galaxy would be included in the

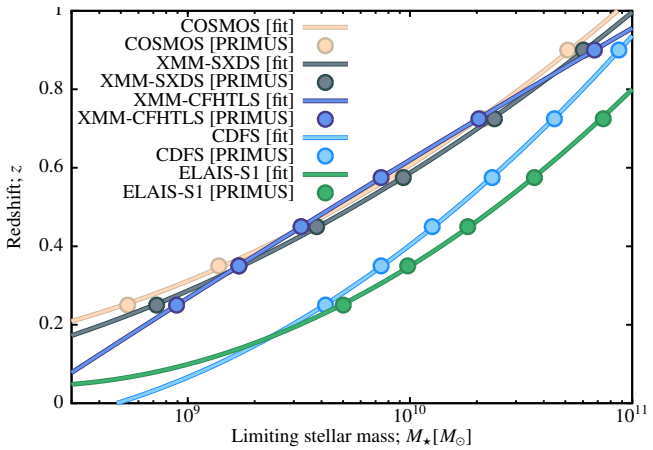

Figure 12.6.: The maximum distance at which a galaxy of given stellar mass can be detected in the sample of Moustakas et al. [2013]. Points show the results obtained from completeness limit data taken from Table 2 of Moustakas et al. [2013], while the lines shows a polynomial fit to these results (given in eqn. 12.254).

sample. Points indicate results from Moustakas et al. [2013], while the line shows a polynomial fits:

$$z_{\max}(M_\star) = +3.51 + m(-0.941 + m(+0.0651)) \quad \text{COSMOS} \tag{12.250}$$
$$z_{\max}(M_\star) = +2.46 + m(-0.730 + m(+0.0542)) \quad \text{XMM-SXDS} \tag{12.251}$$
$$z_{\max}(M_\star) = -3.60 + m(+0.500 + m(-0.0078)) \quad \text{XMM-CFHTLS} \tag{12.252}$$
$$z_{\max}(M_\star) = +5.87 + m(-1.528 + m(+0.0982)) \quad \text{CDFS} \tag{12.253}$$
$$z_{\max}(M_\star) = +6.87 + m(-1.656 + m(+0.1003)) \quad \text{ELAIS-S1} \tag{12.254}$$

where $m = \log_{10}(M_\star/M_\odot)$. We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

12.59.7. Muzzin et al. (2013)

Selected with `surveyGeometryMethod=muzzin2013ULTRAVISTA`, this method describes the survey geometry of Muzzin et al. [2013].

For the angular mask, we generate a MANGLE polygon file, by first defining a rectangle encompassing the bounds of the ULTAVISTA field ($149.373° < \alpha < 150.779°$ and $1.604° < \delta < 2.81°$). From this rectangle, we then remove circles of radii $75''$ around bright stars (i.e. those bright than 10^{th} and 8^{th} magnitudes in the USNO and 2MASS star lists respectively) and radii $30''$ around medium stars (i.e. those bright than 13^{th} and 10.5^{th} magnitudes in the USNO and 2MASS star lists respectively). Finally, we mask regions of one detector for which 75% of pixels are dead by clipping pixels with weights below 0.02 in the K_s-band weight map. These choices match those made in the ULTRAVISTA survey (A. Muzzin, private communication). The solid angle of each mask is computed using the MANGLE `harmonize` command.

To determine the depth as a function of stellar mass, we simply fit the tabulated relations provided by the ULTRAVISTA survey:

$$z_{\max}(M_\star) = \frac{-8364.45 + m(4331.82 + m(-896.596 + m(92.6999 + m(-4.78750 + m(0.0988215)))))}{1 - \exp[(m - 11.24)/0.02]} \tag{12.255}$$

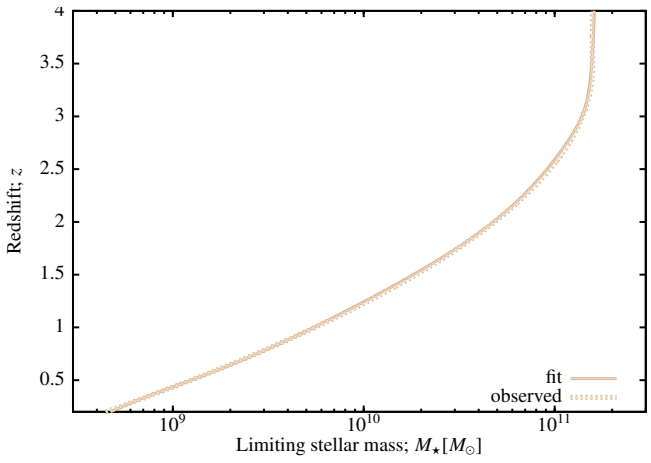

Figure 12.7.: The maximum distance at which a galaxy of given stellar mass can be detected in the sample of Muzzin et al. [2013]. The dotted line shows the results obtained from the ULTRAVISTA survey [Muzzin et al., 2013], while the solid line shows the polynomial fit to these results (given in eqn. 12.255).

where $m = \log_{10}(M_\star/M_\odot)$.

12.59.8. Martin et al. (2010)

Selected with `surveyGeometryMethod=martin2010ALFALFA`, this method describes the survey geometry of Martin et al. [2010].

For the angular mask we use the three disjoint regions defined by $07^{\rm h}30^{\rm m} <$ R.A. $< 16^{\rm h}30^{\rm m}$, $+04° <$ decl. $< +16°$, and $+24° <$ decl. $< +28°$ and $22^{\rm h} <$ R.A. $< 03^{\rm h}$, $+14° <$ decl. $< +16°$, and $+24° <$ decl. $< +32°$ corresponding to the sample of Martin et al. [2010]. When the survey window function is needed we generate randomly distributed points within this angular mask and out to the survey depth. These points are used to determine which elements of a 3D grid fall within the window function.

To estimate the depth of the Martin et al. [2010] sample as a function of galaxy HI mass we first infer the median line width corresponding to that mass. To do so, we have fit the median line width-mass relation from the $\alpha.40$ sample with power-law function as shown in Fig. 12.8. We find that the median line width can be approximated by

$$\log_{10}(W_{50}/\text{km s}^{-1}) = c_0 + c_1 \log_1 0(M_{\rm HI}/M_\odot), \tag{12.256}$$

with $c_0 = -0.770$ and $c_1 = 0.315$. Given the line width, the corresponding integrated flux limit, $S_{\rm int}$, for a signal-to-noise of 6.5 is inferred using equation (A1) of Haynes et al. [2011]. Finally, this integrated flux limit is converted to maximum distance at which the source could be detected using the expression given in the text of section 2.2 of Martin et al. [2010]:

$$M_{\rm HI} = 2.356 \times 10^5 \left(\frac{D}{\text{Mpc}}\right)^2 \left(\frac{S_{\rm int}}{\text{Jy km s}^{-1}}\right). \tag{12.257}$$

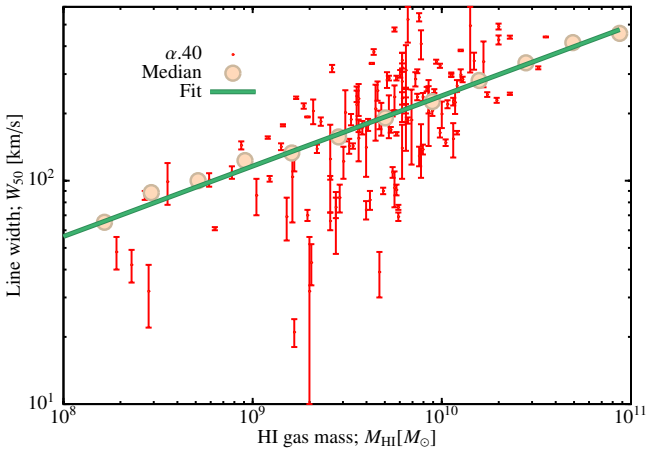

Figure 12.8.: HI line width vs. HI mass as measured from the $\alpha.40$ survey of Martin et al. [2010]. Red points with error bars show individual measurements, while the larger circles indicate the running median of these data. The green line is a power-law fit to the running median as described in eqn. (12.256).

12.59.9. Caputi et al. (2011)

Selected with `surveyGeometryMethod=caputi2011UKIDSSUDS`, this method describes the survey geometry of Caputi et al. [2011].

The angular mask is defined by the boundaries given in Table 12.4 together with a set of rectangular holes fitted to gaps in the galaxy distribution provided by Karina Caputi (private communication). In particular, a set of points randomly distributed in the survey mask is constructed by the script `constraints/dataAnalysis/stellarMassFunctions_UKIDSS_UDS_z3_5/surveyGeometryRandoms.pl`. These points are used to determine which elements of a 3D grid fall within the window function. We compute a solid angle of 1.592×10^{-4} sr for the sample from this window function.

To estimate the depth of the Caputi et al. [2011] sample as a function of galaxy stellar mass we make use of semi-analytic models in the Millennium Database. Specifically, we use the SAMs of Henriques et al. [2012] and Guo et al. (2011; specifically the `Henriques2012a.wmap1.BC03_001` and `Guo2010a..MR` tables in the Millennium Database). For each snapshot in the database, we extract the stellar masses and observed-frame IRAC 4.5μm apparent magnitudes (including dust extinction), and determine the median apparent magnitude as a function of stellar mass. Using the limiting apparent magnitude of the Caputi et al. [2011] sample, 24.0, we infer the corresponding stellar mass.

The end result of this procedure is the limiting stellar mass as a function of redshift, accounting for k-corrections, evolution, and the effects of dust. Figure 12.9 shows the resulting relation between stellar mass and the maximum redshift at which such a galaxy would be included in the sample. Points indicate measurements from the SAM, while the line shows a polynomial fit:

$$z(M_\star) \quad = \quad -56.247 + 5.881 \log_{10}(M_\star/M_\odot). \tag{12.258}$$

We use this polynomial fit to determine the depth of the sample as a function of stellar mass.

Table 12.4.: Boundaries of the angular mask for the survey of Caputi et al. [2011]. Each boundary consists of a great circle segment defined by start and end coordinates (given in tuples of right acesension and declination in units of degrees), together with a "type" which specifies whether points above, below, to the right or left of the boundary are part of the survey (where "above" and "below" refer to declination, and "left" and "right" refer to right acsension).

Start	End	Type
(34.460,-4.648)	(34.750,-4.648)	above
(34.000,-4.908)	(34.460,-4.648)	above
(34.900,-4.920)	(34.750,-4.648)	above
(34.440,-5.518)	(34.905,-5.255)	below
(34.210,-5.518)	(34.440,-5.518)	below
(34.210,-5.518)	(34.000,-5.150)	below
(34.000,-4.908)	(34.000,-5.150)	left
(34.900,-4.920)	(34.905,-5.255)	right

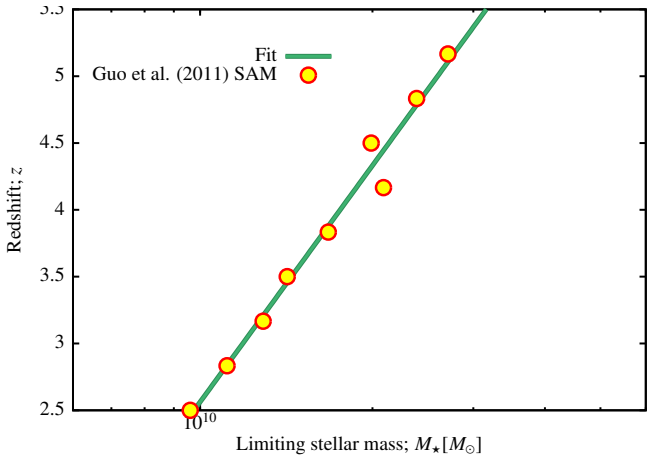

Figure 12.9.: The maximum redshift at which a galaxy of given stellar mass can be detected in the sample of Caputi et al. [2011]. Points show the results obtained using the Henriques et al. [2012] and Guo et al. [2011] models from the Millennium Database, while the lines shows a polynomial fit to these results (given in eqn. 12.258).

13. Additional Output Quantities

13.1. Black Hole Accretion

Properties associated with accretion onto supermassive black holes can be output by setting `blackHoleOutputAccretion=tru`
Currently, two additional properties are output for each node when this option is selected:

`blackHoleAccretionRate` The rate at which the supermassive black hole is accreting mass in $M_\odot$ Gyr^{-1};

`blackHoleJetPower` The power being emitted into jets by the black hole/accretion disk system in $M_\odot$ km^2 s^{-2} Gyr^{-1}.

13.2. Cooling Data

Properties associated with cooling in hot halos can be output by setting `hotHaloOutputCooling=true`.
Currently, two additional properties are output for each node when this option is selected:

`hotHaloCoolingRate` The rate at which gas is cooling from the halo (assuming no sources of heating) in $M_\odot$ Gyr^{-1};

`hotHaloCoolingRadius` The characteristic cooling radius in the halo in Mpc.

13.3. Density Contrast Data

Properties of nodes at density contrasts other than the virial density can be output by setting `[outputDensityContrastData]=`
When selected, this output option requires that a list of density contrasts, Δ (defined in units of the mean density of the Universe), be given in the `[outputDensityContrastValues]` input parameter. For each specified density contrast, two properties are output for each node: `nodeRadius`Δ and `nodeMass`Δ which give the radius enclosing a mean density contrast of Δ and the mass enclosed within that radius. The parameter `[outputDensityContrastDataDarkOnly]` controls whether density contrasts are measured for total mass (`false`) or dark matter mass only (`true`). In the latter case, density contrasts are defined relative to the mean dark matter density of the Universe.

13.4. Descendent Node Index

By setting `[outputDescendentIndices]=true` the index of the node containing the galaxy to which each current galaxy will belong at the next output time (i.e. the forward descendent) will be written to the output file. To clarify, this will be the index of the node into which the galaxy descends, or the index of a node with which it merges prior to the next output time (and if that node merges with another, the index will be of that node and so on).

Note that, to operate correctly, information about which node a given node may merge with (and when this merger will happen) must be available. This is typically available in merger trees read from file providing `[treeNodeMethodSatelliteOrbit]` and `[mergerTreeReadPresetMergerTimes]` are both set to `true`. When using randomly assigned satellite orbits and merger times, information on when merging

occurs does not exist until a node becomes a satellite. Thus, if the node becomes a satellite after the current output, but before the next output, there is no way to know which node it will belong to at the next output (in such cases, the fallback assumption is no merging).

13.5. Host Node Index

By setting `[outputHostIndices]=true` the index of the node which hosts each node will be output to the `hostIndex` dataset. For unhosted nodes (i.e. nodes which are not subhalos), a value of -1 is output instead.

13.6. Half-Light Radii Data

Half-light radii and masses enclosed within them can be output by setting `[outputHalfLightData]=true`. When selected the half-light radius in each specified luminosity band is output as `[halfLightRadius{luminosityID}]` (in Mpc), where `{luminosityID}` is the usual luminosity identifier suffix, and the total (dark + baryonic) mass within that radius is output as `[halfLightMass{luminosityID}]` (in $M_\odot$).

13.7. Half-Mass Radii

Half-mass radii can be output by setting `[outputHalfMassData]=true`. When selected the half-mass radius is output as `[halfMassRadius]` (in Mpc).

13.8. Halo Model Quantities

The following quantities related to galaxy clustering are output if `[outputHaloModelData]` is set to true:

`nodeBias` The large scale, lineary theory bias for each node. For satellite nodes, this corresponds to the bias of their host halo;

`isolatedHostIndex` The index of the isolated node in which this node lives. This is identical to `nodeIndex` for non-satellite nodes.

In addition to these quantities output for each node, setting `[outputHaloModelData]=true` causes the creation of a `haloModel` group in the Galacticus output file. This group contains the following:

`wavenumber` A dataset giving the wavenumbers (in units of Mpc^{-1}) at which all output power spectra are tabulated. The minimum and maximum wavenumbers to tabulate are determined by the `[haloModelWavenumberMinimum]` and `[haloModelWavenumberMaximum]` parameters respectively, while the number of points to tabulate in each decade of wavenumber is determined by the `[haloModelWavenumberPointsPerDecade]` parameter.

`powerSpectrum` A dataset giving the linear theory power spectrum (in units of Mpc^3 normalized to $z = 0$ at each wavenumber specified in the `wavenumber` dataset.

`Output{i}/mergerTree{j}/fourierProfile{k}` A dataset giving the Fourier transform of the dark matter halo density profile (dimensionless and normalized to unity at small wavenumber) for the node with index `k` in merger tree with index `j` at output number `i`. Profiles are written only for nodes which are isolated, and are tabulated at the wavenumbers given in the `wavenumber` group. Note that wavenumbers are assumed to be comoving.

Finally, each numbered output group is given two additional attributes, `linearGrowthFactor` and `linearGrowthFactorLogDerivative` which give the growth factor, D, and its logarithmic derivative, $\mathrm{d}\ln D/\mathrm{d}\ln a$ at the output time.

The information output can be used to construct galaxy power spectra and correlation functions.

13.9. Lightcone Coordinates

The position (and velocity and redshift) of a galaxy within a lightcone will be output if the parameter `[outputLightconeData]=true`. In such cases, the following properties will be output for all galaxies:

`lightconePositionX` Position of the galaxy (in comoving Mpc) along the radial direction of the lightcone;

`lightconePositionY` Position of the galaxy (in comoving Mpc) along the 1$^{\mathrm{st}}$ angular direction of the lightcone;

`lightconePositionZ` Position of the galaxy (in comoving Mpc) along the 2$^{\mathrm{nd}}$ angular direction of the lightcone;

`lightconeVelocityX` Velocity of the galaxy (in km/s) along the radial direction of the lightcone;

`lightconeVelocityY` Velocity of the galaxy (in km/s) along the 1$^{\mathrm{st}}$ angular direction of the lightcone;

`lightconeVelocityZ` Velocity of the galaxy (in km/s) along the 2$^{\mathrm{nd}}$ angular direction of the lightcone;

`lightconeRedshift` Redshift of the galaxy in the lightcone[1];

`angularWeight` The mean number density of this galaxy per unit area on the sky (in degrees^{-2}).

In order to allow this output a lightcone geometry must be specified, see §16.4.1.

13.10. Main Branch Evolution

The evolution of main branch galaxies can be recorded by setting `[timestepRecordEvolution]=true`. When set, the evolution of each main branch galaxy will be recorded at a set of `[timestepRecordEvolutionSteps]` timesteps spaced logarithmically in cosmic time between `[timestepRecordEvolutionBegin]` and `[timestepRecordEvolutionEnd]`.

This recorded evolution will be written to the group `mainProgenitorEvolution` in the Galacticus output file. Within that group two datasets, `time` and `expansionFactor`, give the times and expansion factors at which evolution was recorded. Then for each merger tree two datasets, `stellarMass<N>` and `totalMass<N>` (where `<N>` is the merger tree index), give the stellar and total baryonic mass of the main branch progenitor at each timestep.

13.11. Main Branch Status

The status of each node with respect to the main branch of its merger tree can be output by setting `[outputMainBranchStatus]=true`. When set, the status will be output as `nodeIsOnMainBranch`, with a value of 1 indicating that the node is a primary progenitor of the final halo (i.e. is on the main branch of the tree) and a value of 0 indicating that it is not.

[1] Note that this will not, in general, be precisely the same as the redshift corresponding to the output time.

13.12. Mass Profile Data

Masses enclosed within specific radii can be output by setting `[outputMassProfileData]=true`. When selected, this output option requires that a list of radii, r (in Mpc), be given in the `[outputMassProfileRadii]` input parameter. For each specified radius, the total (dark + baryonic) mass will be output as `massProfile`r.

13.13. Merger Tree Links and Node Isolation

The following properties are output to permit the merger tree structure to be recovered:

`nodeIndex` A unique[2] (within a tree) integer index identifying the node;

`parentIndex` The index of this node's parent node (or -1 if it has no parent);

`siblingIndex` The index of this node's sibling node (or -1 if it has no sibling);

`satelliteIndex` The index of this node's first satellite node (or -1 if it has no satellites);

`nodeIsIsolated` Will be 0 for a node which is a subhalo inside some other node (i.e. a satellite galaxy) or 1 for a node that is an isolated halo (i.e. a central galaxy).

The `nodeIndex` property corresponds by default to the index of the node in the original merger tree. This means that as a galaxy evovles through the tree and, in particular, gets promoted into a new halo the index associated with a galaxy will change. This is useful to identify where the galaxy resides in the original (unevolved) tree structure, but does not allow galaxies to be traced from one output to the next using their `nodeIndex` value. By setting `[nodePromotionIndexShift]=true` this behavior can be changed such that the value of `nodeIndex` will reflect the index of the earliest progenitor node along the main branch of the current node. As such, this index will remain the same for a given galaxy during its evolution. These two alternative algorithms for propagating node indices are illustrated in Figure 13.1.

13.14. Merger Tree Data for Rendering

Data on the structure of a merger tree and its halos useful for rendering the tree as a 3-D structure can be output using the `Merger_Trees_Render` module. Calling `Merger_Trees_Render_Dump` with a tree as the only argument will cause the tree structure will be dumped to a file named `render_`⟨`treeIndex`⟩`_`⟨`outputIndex`⟩`.hdf5` where ⟨`treeIndex`⟩ is the index of the tree and ⟨`outputIndex`⟩ is an incremental counter that tracks the number of outputs for this tree. The output is a simple HDF5 file containing the following datasets:

`nodeIndex` Index of the node;

`parentIndex` Index of the parent node;

`childIndex` Index of the child node;

`time` Time of the node;

`expansionFactor` Corresponding expansion factor;

`radiusVirial` Virial radius of the node;

`position` (x, y, z) position of the node.

[2] Node indices are typically unique, but there is no actual requirement within Galacticus that this must be the case. A merger tree construction method could create nodes with non-unique indices.

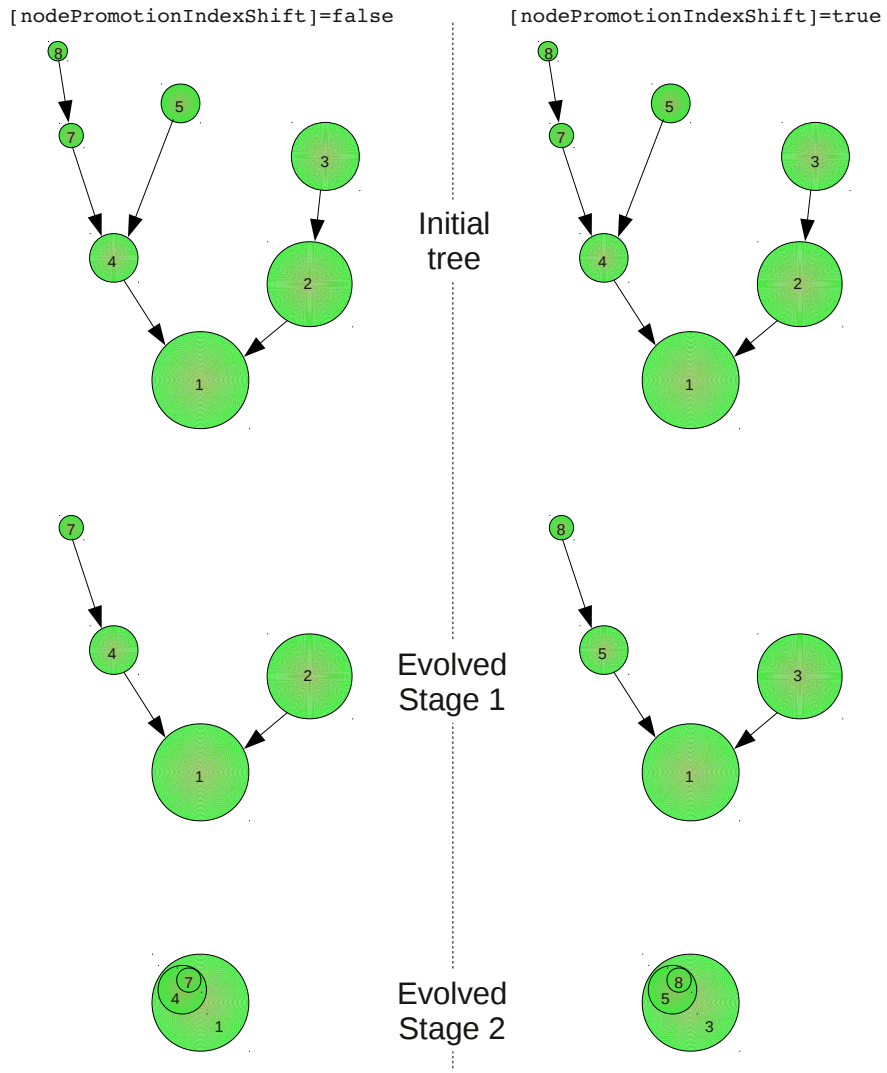

Figure 13.1.: Illustration of options for the propagation of node indices during node promotion events. Two identical trees (top row) are evolved with `[nodePromotionIndexShift]=false` (left column) and `[nodePromotionIndexShift]=true` (right column). The middle and lower rows indicate the resulting node indices after two stages of tree evolution.

13.15. Merger Tree Structure

The structure of each merger tree can optionally be dumped to a file suitable for post-processing with DOT after every step of evolution. To request this output set `[mergerTreesDumpStructure]=true`. After each evolution step the tree structure will be dumped to a file named `mergerTreeDump:⟨treeIndex⟩:⟨outputIndex⟩.gv` where ⟨`treeIndex`⟩ is the index of the tree and ⟨`outputIndex`⟩ is an incremental counter that tracks the number of outputs for this tree. These files can be processed with DOT to produce a diagram of the tree structure. The node currently being evolved will be highlighted in green. This output option makes use of the `Merger_Trees_Dump` module to create the outputs.

13.16. Most Massive Progenitor

Setting `[outputMostMassiveProgenitor]=true` causes the property `isMostMassiveProgenitor` to be output. This property will be 1 for the most massive progenitor node in a tree at each output time and 0 for all other nodes.

13.17. Projected Density

Setting `[outputProjectedDensityData]=true` causes the projected density of the node to be output at specified radii. The radii and types of projected density to output is specified by the `outputProjectedDensityRadii` parameter. This parameter's value can contain multiple entries. Each entry is of the form:

```
radiusType:componentType:massType:loading?:radius
```

The elements of this colon-separated specifier determine the radius at which the projected density is computed, which components/mass types should be counted, and whether baryonic loading of the halo should be accounted for. The elements have the following meaning:

`radius` the numerical value of the radius at which to compute the projected density (with units specified by the `radiusType` element);

`radiusType` specifies the units of the `radius` element—valid options are `diskRadius`, `diskHalfMassRadius`, `spheroidRadius`, `spheroidHalfMassRadius`, `darkMatterScaleRadius`, `virialRadius`, just `radius` (which implies radii are given in units of Mpc), `galacticMassFraction{<fraction>}`, or `galacticLightFraction{<fraction>}{<luminosity>}`, where the final two form specify a radius containing a fixed `<fraction>` of the galactic mass or light respectively (for the case of galactic light, `<luminosity>` specifies the band, e.g. `SDSS_r:rest:z0.0000`);

`componentType` specifies which components of the node should be counted—allowed values are `all`, `disk`, `spheroid`, `hotHalo`, `darkHalo`, and `blackHole`;

`massType` specifies which types of mass should be counted—allowed values are `all`, `dark`, `baryonic`, `galactic`, `gaseous`, `stellar`, and `blackHole`;

`loading?` option should be either `loaded` or `unloaded`, and specifies whether the effect of baryonic loading (i.e. adiabatic contraction) should be included in the calculation of the projected density.

13.18. Rotation Curve

Setting `[outputRotationCurveData]=true` causes the rotation curve of the node to be output at specified radii. The radii and types of rotation curve to output is specified by the `outputRotationCurveRadii` parameter. This parameter's value can contain multiple entries. Each entry is of the form:

```
radiusType:componentType:massType:loading?:radius
```

The elements of this colon-separated specifier determine the radius at which the rotation curve is computed, which components/mass types should be counted, and whether baryonic loading of the halo should be accounted for. The elements have the following meaning:

`radius` the numerical value of the radius at which to compute the rotation curve (with units specified by the `radiusType` element);

`radiusType` specifies the units of the `radius` element—valid options are `diskRadius`, `diskHalfMassRadius`, `spheroidRadius`, `spheroidHalfMassRadius`, `darkMatterScaleRadius`, `virialRadius`, just `radius` (which implies radii are given in units of Mpc), `galacticMassFraction{<fraction>}`, or `galacticLightFraction{<fraction>}{<luminosity>}`, where the final two form specify a radius containing a fixed `<fraction>` of the galactic mass or light respectively (for the case of galactic light, `<luminosity>` specifies the band, e.g. `SDSS_r:rest:z0.0000`);

`componentType` specifies which components of the node should be counted—allowed values are `all`, `disk`, `spheroid`, `hotHalo`, `darkHalo`, and `blackHole`;

`massType` specifies which types of mass should be counted—allowed values are `all`, `dark`, `baryonic`, `galactic`, `gaseous`, `stellar`, and `blackHole`;

`loading?` option should be either `loaded` or `unloaded`, and specifies whether the effect of baryonic loading (i.e. adiabatic contraction) should be included in the calculation of the rotation curve.

13.19. Satellite Mergers

Setting `[outputSatelliteMergers]` to `true` will cause data to be output for each satellite merger event. Data is stored to datasets in the `satelliteMergers` group. Datasets output are:

`[indexHost]` the index of the host halo in the merger;

`[indexSatellite]` the index of the satellite halo in the merger;

`[indexTree]` the index of the merger tree in which the merger occurred;

`[massHost]` the mass of the host halo;

`[massSatellite]` the mass of the satellite halo;

`[time]` the time at which the merger occurred.

13.20. Satellite Orbital Pericenter

Setting `[outputSatellitePericenterData]` to `true` will cause the pericentric values of the radius and velocity of each satellite node's orbit to be output as `satellitePericenterRadius` and `satellitePericenterVelocity` respectively.

13.21. Star Formation Rates

By default the star formation rate in each galaxy is *not* output. However, setting `[diskOutputStarFormationRate]` to true will cause the current star formation rate in the disk of each galaxy to be output as `diskStarFormationRate` (in units of $M_\odot$/Gyr). The `[spheroidOutputStarFormationRate]` has the same effect for the spheroid component.

13.22. Velocity Dispersion

Setting `[outputVelocityDispersionData]=true` causes the velocity dispersion of the node to be output at specified radii, for specified components. The radii, components and type of velocity dispersion to output are specified by the `outputVelocityDispersionRadii` parameter. This parameter's value can contain multiple entries. Each entry is of the form:

```
radiusType:componentType:massType:loading?:direction:radius
```

The elements of this colon-separated specifier determine the radius at which the velocity dispersion is computed, which component/mass type the velocity dispersion should be computed for, whether baryonic loading of the halo should be accounted for, and for which direction the velocity dispersion should be computed. The elements have the following meaning:

`radius` the numerical value of the radius at which to compute the velocity dispersion (with units specified by the `radiusType` element);

`radiusType` specifies the units of the `radius` element—valid options are `diskRadius`, `diskHalfMassRadius`, `spheroidRadius`, `spheroidHalfMassRadius`, `darkMatterScaleRadius`, `virialRadius`, just `radius` (which implies radii are given in units of Mpc), `galacticMassFraction{<fraction>}`, or `galacticLightFraction{<fraction>}{<luminosity>}`, where the final two form specify a radius containing a fixed `<fraction>` of the galactic mass or light respectively (for the case of galactic light, `<luminosity>` specifies the band, e.g. `SDSS_r:rest:z0.0000`);

`componentType` specifies which component of the node the velocity dispersion should be computed for—allowed values are `all`, `disk`, `spheroid`, `hotHalo`, `darkHalo`, and `blackHole`[3];

`massType` specifies which type of mass the velocity dispersion should be computed for—allowed values are `all`, `dark`, `baryonic`, `galactic`, `gaseous`, `stellar`, and `blackHole`;

`loading?` option should be either `loaded` or `unloaded`, and specifies whether the effect of baryonic loading (i.e. adiabatic contraction) should be included in the calculation of the velocity dispersion;

`direction` should be one of `radial` (computes the radial component of velocity dispersion), `lineOfSight{<luminosity>}` (computes the line-of-sight velocity dispersion), `lineOfSightInteriorAverage{<luminosity>}` (computes the line-of-sight velocity dispersion averaged interior to the given radius), or `lambdaR{<luminosity>}` (computes the λ_R statistic of Cappellari et al. 2007)—in the latter three cases `{<luminosity>}` specifies which band should be used to weight the velocity dispersion, alternatively setting `{<luminosity>}=mass` (or just leaving off this specifier entirely) will use mass weighting instead.

13.23. Virial Quantities

The following quantities related to the virialized region of each node are output if `outputVirialData` is set to true:

`nodeVirialRadius` The virial radius (following whatever definition of virial overdensity was selected in Galacticus) in units of Mpc;

`nodeVirialVelocity` The circular velocity at the virial radius (in km/s).

[3] Note that attempting to compute the velocity dispersion for a black hole or disk for example won't make any sense.

Part IV.

Development

In this Part we focus on how to modify Galacticus to meet your own needs. Galacticus is designed in a modular way to make it as simple as possible to introduce new implementations of physical processes or new galactic components without breaking the rest of the code. Nevertheless, some understanding of the structure of the code is necessary. In particular, Galacticus will happily compile and run calculations that make no physical sense whatsoever—it's up to you to ensure that the changes you make are physically reasonable and consistent with the behavior of the rest of the code.

14. Developing Galacticus

The following is a quickstart guide to making changes to the Galacticus source code and contributing them back to the project. Note that the preferred method to do this is through BitBucket.

14.1. Getting Started

It's easy to begin working with and changing the Galacticus source code. Assuming you have Mercurial ("`hg`") installed, just do:

```
hg clone https://abensonca@bitbucket.org/galacticusdev/galacticus galacticus
```

and you have a cloned copy of the Galacticus repository in the `galacticus` directory.

14.1.1. Using BitBucket

If you plan to contribute changes back to the Galacticus] project (please do!), you should consider using BitBucket. After you've created an account for yourself at BitBucket, you can "fork" the Galacticus repository to have your own working copy. This can be done as follows:

- visit the Galacticus repository on `BitBucket` at `https://bitbucket.org/abensonca/galacticus/overview`;
- click on the "Fork" button—you'll be presented with a form;
- fill out the form (setting a name for your fork, a short description, etc.), then click the "Fork repository" button;
- after the fork completes, you'll be taken to the overview page for your forked repository.

.

You'll now want to clone this forked repository to your local system. Click on the "Clone" button and copy the `hg clone` command presented there (you want the `SSH` version so that you can push changes back to this repository). Run this command on your local system to get a cloned copy of your new repository. You can now work with this repository, make any changes, and commit then. We'll discuss how to send these changes back to BitBucket, and back to the Galacticus project below.

14.2. Making Simple Changes

If you want to make some relatively minor changes to the Galacticus code, such as fixing a typo, adding a new filter, etc. you can just make changes directly on the `default` branch (i.e. at the point of active development). To do this, make sure you're at `default`:

```
hg pull
hg update default
```

Then make your changes, add new files, etc. Once you're done, first check if there have been any changes to `default` since you `pull`ed:

```
hg incoming
```

If any new changesets are shown, us `hg pull -u` to merge these in to your working copy. Then commit your changes:

```
hg commit
```

Your changes are now commited to your cloned repository.

14.2.1. Contributing Your Changes Back To Galacticus

Once you've committed your changes, you can contribute them back to the Galacticus project.

Via E-mail

If you just cloned the Galacticus repository directly you can send a patch containing your changes by e-mail to abenson@carnegiescience.edu. First, create the patch file using:

```
hg export -r begin:end > changes.diff
```

where `begin` and `end` are the first and last revisions that you want to include (you can specify more complicated sets of revisions of course). Then simply attached the `changes.diff` file to an e-mail. It will be merged into the Galacticus project using

```
hg import changes.diff
```

Using BitBucket

If you forked the Galacticus repository on BitBucket, you can now push your changes back to `BitBucket` using

```
hg push
```

If you want to contribute these changes back to the Galacticus project the best way to do so is to create a "pull request". Simply visit your forked respository on BitBucket and click the "Pull request" button. The form you're presented with allows you to choose which branch in your respository you want to send changes from, and which branch in the Galacticus project you want them contributed to. Add a title and description of your changes (and, optionally, check the "Close branch" box if you're done with this branch of development) then click "Create pull request". Assuming your code looks godo and works, it can then be pulled into the Galacticus project.

14.3. Making Bigger Changes

For bigger changes, particularly those where you're adding a new feature, we recommend using Mercurial's "feature branches". These provide a permanent record of for which feature each changeset was added. Using feature branches is straightforward. Begin with `default` and create a new branch:

```
hg update default
hg branch myNewFeature
```

where `myNewFeature` is a name for your feature branch. Then begin working, make changes, add new files etc. You can make commits when necessary (and it's good to make several small commits rather than one big one). You should merge `default` into your feature branch as often as possible to avoid them getting out of sync (which makes for difficulty later when you want to merge your feature branch back into `default`):

```
hg update myFeatureBranch
hg merge default
hg commit -m "merged default into myFeatureBranch"
```

Once the feature branch is stable, you can merge it back into `default`:

```
hg update default
hg merge myFeatureBranch
hg commit -m "merged myFeatureBranch"
```

Once you're done developing this feature, you should close the feature branch:

```
hg commit --close-branch -m "finished my feature"
```

Note that you can always go back and work on a feature branch later, after you have closed it. Just do:

```
hg up myFeatureBranch
hg merge default
hg commit -m "merged default into myFeatureBranch"
```

then continue to work with your feature branch as normal (don't forget to close it again when you're finished working with it).

14.4. Releases

Each release of Galacticus exists as a separate branch within the main Galacticus repository. To work with a particular release use

```
hg update v0.9.2
```

replacing the version number with whichever version you want. To get back to the development tip use

```
hg update default
```

14.4.1. Bug Fixes In Releases

To make a bugfix in a release, simply `hg update` to that release, fix the bug, and commit your changes. In many cases you'll want to fix the same bug in later releases and also in `default`. To do that, just `hg update` to each branch in turn, use `hg merge fixedBranch` (where "`fixedBranch`" is the name of the branch in which you fixed the branch, and then commit the merge. Once the bug has been fixed you can contribute the fix back to the Galacticus project using the methods described above.

14.5. The Galacticus Build System

Galacticus use a GNU Make-based build system. Dependencies are automatically discovered, and extensive meta-programming and preprocessing of source files is undertaken as part of the build. As a result, the build system is complicated. In this section the build system is described and detailed.

14.5.1. The Makefile

Files generated during the build (with the exception of final executables) are written to the directory specified by the `BUILDPATH` environment variable. This is normally `work/build/` (and is set by the `Makefile`) unless a special build configuration is requested.

14.5.2. Automatic Discovery

Interdependencies between source files, together with requirements for auto-generated code are automatically discovered during the build process by processing of source files. All such automatic discovery is described below.

Code Directive Parsing

The modular nature of Galacticus is enabled through the use of directives embedded within the source code (XML documents embedded as comment lines starting with a special tag) which instruct the build system how to link together the various functions. Parsing of these directives is handled by the `codeDirectivesParse.pl` script.

For `include` directives (which generate files that get included into the source), the script generates `$(BUILDPATH)/*.xml` files which describe the directive, and `$(BUILDPATH)/Makefile_Directives` which contains rules for building those include files.

The script also outputs a file `$(BUILDPATH)/directiveLocations.xml` which provides list of files that contain each directive. This is used by other scripts to permit rapid processing of files associated with each directive.

Allocatable Arrays

Types and ranks of allocatable arrays required by the Galacticus are discovered by the `allocatableArrays.pl` script. Source files are parsed for dimensionful, allocatable intrinsic types. All such combinations of type and rank are stored to a file `$(BUILDPATH)/allocatableArrays.xml`. The content of this file is later used to build appropriate memory allocation and deallocation functions (see §14.5.3).

Executable Files

Files which produce executables (including the `Galacticus.exe` executable) are discovered by the `scripts/build/findExecu` script, which generates rules describing how these files should be built, along with all of their dependencies, and writes them to `$(BUILDPATH)/Makefile_All_Execs`. All Fortran files in the `source` directory are parsed, and executable files are identified as those containing a `program` statement. All executables so identified are also added to the list of objects that will be built by `make all`.

Modules Provided

Determination of which files provide which Fortran modules is carried out by the `scripts/build/moduleDependencies.pl` script, which generates rules describing these dependencies (and how to build the module file by compiling the corresponding source file) and writes them to `$(BUILDPATH)/Makefile_Module_Dependencies`.

Additionally, rules are generated which describe how to build the following classes of file:

`*.mod.d` Contains a list of all object files upon which the module depends. Used in constructing the final set of objects which must be linked to build an executable.

`*.mod.gv` Contains a list of all source files upon which the module depends. Used in constructing GraphViz visualizations of dependencies.

`*.m` Contains a list of all modules provided by the corresponding object file. Used when building object files to test whether corresponding module files have been changed—allows avoidance of recompilation cascades if modules do not need to be updated (i.e. if the modules do not differ as judged by the `scripts/build/compareModules.pl` script).

Modules Used

Determination of which files use which Fortran modules is carried out by the `scripts/build/useDependencies.pl` script, which generates rules describing these dependencies and writes them to `$(BUILDPATH)/Makefile_Use_Dependencies`.

Additionally, rules are generated which describe how to build the following classes of file:

`*.d` Contains a list of all object files upon which each object file depends. Used in constructing the final set of objects which must be linked to build an executable.

`*.gv` Contains a list of all source files upon which each file depends by virtue of `use` statements. Used in constructing GraphViz visualizations of dependencies.

`*.fl` Contains a list of libraries upon which each object file depends. Used in constructing the final set of libraries which must be linked with the executable.

Included Files

Dependencies on files due to the use of "`include`" statements (in both Fortran and C source files) are discovered by the `scripts/build/includeDependencies.pl` script, which generates rules describing these dependencies and writes them to `$(BUILDPATH)/Makefile_Include_Dependencies`.

All Fortran and C/C++ source files in the `source` directory are parsed. Files specified in any include statement in a source file are added as a dependency of that source file if unless the source file is C/C++ and the named include file can be found in either `source/`, a standard system include path, or in any include path specified in the `GALACTICUS_CFLAGS` or `GALACTICUS_CPPFLAGS` environment variables.

Parameter Dependencies

All runtime parameters upon which a given executable may depend are discovered by the `scripts/build/parameterDependen` script, which generates XML files listing these parameters and writes them to `$(BUILDPATH)/<executableName>.parameters` All Fortran and C++ files in the `source` directory are parsed, and embedded parameter definitions (i.e. embedded XML blocks in lines beginning "!" for Fortran or "//" for C++ with root element `inputParameter`) are identified. Any files included into a source file are also searched. In the case of Fortran source files, `source/*.F90`, the corresponding preprocessed file, `$(BUILDPATH)/*.p.F90`, will be searched for parameter dependencies.

14.5.3. Code Generation

During build, code is generated automatically. Much of this is to link together functions within GALACTICUS (thereby permitting the modular nature of GALACTICUS), but also includes generation of various utility functions. All code generation is described below.

Memory Management Functions

Functions for allocation and deallocation of intrinsic-type arrays are generated by the `memoryManagementFunctions.pl` script. Utilizing the list of such types in the `$(BUILDPATH)/allocatableArrays.xml` file (see §14.5.2) overloaded functions are created for each type. These memory management functions keep track of the total amount of memory allocated.

`memoryManagementFunctions.pl`

Directives

Generation of code to implement the functionality of `include` directives is carried out by the `buildCode.pl` script. This script simply reads an XML file generated by the `codeDirectivesParse.pl` (see §14.5.2), calls the appropriate function to generate the necessary code, passes this through the preprocessor (see §15.2), and outputs the result to the appropriate include file.

Pre- and Post-processing

Before being compiled, all Fortran source files are passed through a tree-based preprocessor. The functionality of this preprocessor is described in §15.2. The preprocessor is invoked on each source file by the `preprocess.pl` script, which takes a `source/*.F90` file as input and outputs a preprocessed file `$(BUILDPATH)/*.p.F90`.

Output from the `gfortran` compiler is directed through the `postprocess.pl` script. This script currently performs the following functions:

- Builds a map from line numbers in the preprocessed source file back to line numbers in the unpreprocessed source, and translates line numbers in any error or warnings messages from the compiler into line numbers in the unpreprocessed source;
- Filters out incorrect warning messages about the lack of scalar finalizers (see GCC PR58175);
- Checks for unused function attributes in the source and filters out warnings about these unused functions.

14.5.4. Build Files

All files involved in the build process are summarized below.

`scripts/build/allocatableArrays.pl`: Discovers dimensionful, allocatable, intrinsic-typed arrays in the source code, and generates a summary of their types and ranks to the file `$(BUILDPATH)/allocatableArrays.xml` (see §14.5.2);

`scripts/build/buildCode.pl`: Acts upon `include` directives embedded in the source code and generates the corresponding include file (see §14.5.3);

`scripts/build/codeDirectivesParse.pl`: Discovers and parses directives embedded in source files. Generates `make` rules for the resulting dependencies, a file providing a mapping of which files contain each directive, and rule files describing how to build each include file resulting from a `include` directive;

`scripts/build/compareModuleFiles.pl`: Tests whether two Fortran module files are identical (ignoring timestamp information). Used to avoid updating modules when not necessary and so avoids recompilation cascades;

`scripts/build/includeDependencies.pl`: Discovers (and generates rules for) dependencies between files arising from the use of "`include`" statements (see §14.5.2);

`scripts/build/executableSize.pl`: Generates a file containing details of the size of each generated executable which can be used at runtime for memory reporting (see §14.5.2);

`scripts/build/findExecutables.pl`: Discovers (and generates rules for) files which generate executables (see §14.5.2);

`scripts/build/libraryDependencies.pl`: Determines the set of libraries that must be linked with each executable, and ensures they are ordered correctly for static linking;

`scripts/build/memoryManagementFunctions.pl`: Generates memory allocation/deallocation functions for allocatable intrinsic arrays (see §14.5.3);

`scripts/build/moduleDependencies.pl`: Discovers (and generates rules for) dependencies of module files on their source file statements (see §14.5.2);

`scripts/build/parameterDependencies.pl`: Determines all parameters upon which a given executable depends (see §14.5.2);

`scripts/build/postprocess.pl`: Postprocesses the output of the `gfortran` compiler to remove spurious warnings and provide line numbers in warning/error reports that point into the unpreprocessed source files (see §14.5.3);

`scripts/build/preprocess.pl`: Preprocesses Fortran source code to provide various extended functionality (see §14.5.3);

`scripts/build/useDependencies.pl`: Discovers (and generates rules for) dependencies between files originating from module `use` statements (see §14.5.2);

`$(BUILDPATH)/Makefile_All_Execs`: Contains rules describing how to build the executable file for each distinct program—generated by `scripts/build/findExecutables.pl` (see §14.5.2);

`$(BUILDPATH)/Makefile_Component_Includes`: Describes dependencies on the `nodeComponent` class hierarchy module on include files which implement specific functionality for individual node component implementations;

`$(BUILDPATH)/Makefile_Directives`: Describes rules for building include files for `include` directives;

`$(BUILDPATH)/Makefile_Include_Dependencies`: Contains rules describing the dependencies of source file on files included via "`include`" statements—generated by `scripts/build/includeDependencies.pl` (see §14.5.2);

`$(BUILDPATH)/Makefile_Module_Dependencies`: Contains rules which describe how to build module files from their source files (see §14.5.2);

`$(BUILDPATH)/Makefile_Use_Dependencies`: Contains rules which describe dependencies between source file originating from module `use` statements (see §14.5.2);

`$(BUILDPATH)/allocatableArrays.xml`: Contains a summary of the types and ranks of dimensionful, allocatable, intrinsic-type arrays for which memory allocation/deallocation functions will be generated (see §14.5.2);

`$(BUILDPATH)/directiveLocations.xml`: Contains a map of which files contain each code directive (see §14.5.2);

`$(BUILDPATH)/*.xml`: Contain rules for building files for `include` files (see §14.5.2);

`$(BUILDPATH)/*.d`: Contain lists of dependencies on object files, and are accumulated to find the final set of files which must be linked to build each executable (see §14.5.2 & §14.5.2);

`$(BUILDPATH)/*.m`: Contain lists of modules provided by each object file, and are used during testing whether modules have been updated (see §14.5.2);

`$(BUILDPATH)/*.fl`: Contain lists of libraries upon which each object file dependes, and are used to determine the final set of libraries which must be linked with each executable (see §14.5.2);

`$(BUILDPATH)/*.gv`: Contain lists of source files upon which each file depends and are used in the construction of GraphViz representations of file dependencies (see §14.5.2 & §14.5.2);

`$(BUILDPATH)/*.Inc`: Unpreprocessed include files generated from `include` dependencies (see §14.5.2);

`$(BUILDPATH)/*.inc`: Preprocessed include files generated from `include` dependencies (see §14.5.2);

`$(BUILDPATH)/*.p.F90`: Preprocessed Fortran source files (see §14.5.3);

`$(BUILDPATH)/*.parameters.xml`: Contain lists of parameters upon which an executable depends (see §14.5.2);

`$(BUILDPATH)/*.size`: Contain the size of each executable file built, and are used at runtime for memory reporting purposes—generated by `scripts/build/executableSize.pl` (see §14.5.2).

15. Coding Galacticus

15.1. Node Class Hierarchy Builder

The hierarchy of classes describing a merger tree node and its galaxy (i.e. `treeNode`, `nodeComponent`, `nodeComponentBasic`, `nodeComponentBasicStandard`, etc.) are built automatically to realize the set of component implementations and properties specified in source files.

15.1.1. Variable Definitions

Throughout the node objects builder code, Fortran variables are defined using a common specification. This is a simple hash containing the following entries:

intrinsic a string specifying the intrinsic Fortran type (`integer`, `logical`, `real`, `double precision`, `complex`, `double complex`, `type`, `class`, `procedure`);

type *[optional, except for* `type` *and* `class` *instrinics]* a string specifying the type of the variables;

attributes an array of strings specifying all attributes of the variables;

variables an array of strings giving the names of the variables.

For example, rank-1, long integer arguments which will not be modified in their function would be specified as:

```
{
  intrinsic  => "integer",
  type       => "kind_int8",
  attributes => [ "dimension(:)", "intent(in)" ],
  variables  => [ "argument1", "argument2" ]
}
```

15.1.2. The `$build` Data Structure

The `$build` data structure is used to accumulate all objects, variables, interfaces, and functions needed to build the class hierarchy used to represent nodes and components in Galacticus. At the end of the node objects build process, this object is processed to generate the required Fortran code. The following subsections describe how to add information to this object.

Component Classes and Implementations

A reference to a hash of structures which define all component classes, keyed by class name, is provided as `$build->{'componentClasses'}`. Each component class structure has the form:

```
{
 name    => <name of the class>,
 members => <reference to a hash of structures which define all member implementation of the class>
}
```

Each member implementation structure has the form:

```
{
 name       =>             <name of the implementation>,
 properties => property => <reference to a hash of structures which define all properties of this implem
}
```

Types

Definitions of derived types are accumulated to the hash `$build->{'types'}`, with the key of each entry being the derived type's name. Each derived type structure has the form:

```
{
 name           => <name of the derived type>
 comment        => <a description of the type>
 isPublic       => <1 if the class should have public visbility, 0 otherwise>
 dataContent    => <variable list containing all data for this class>
 boundFunctions =>
  [
   {
    type        => <procedure|generic>
    descriptor  => <a function descriptor data structure> [optional]
    name        => <name of the bound method>
    function    => <name of function to bind to> [optional; not required if descriptor is provided]
    description => <LaTeX-syntax description of the method> [optional; not required if descriptor is pro
    returnType  => <LaTeX-syntax return type of the method> [optional; not required if descriptor is pro
    arguments   => <LaTeX-syntax definition of all arguments to the method> [optional; not required if d
   }
  ]
}
```

The preferred approach is to provide a function descriptor (see §15.1.2), and to omit the `function`, `description`, `returnType`, and `arguments` entries (which will be inferred from the function descriptor). The `function`, `description`, `returnType`, and `arguments` entries will eventually be deprecated in favor of the `descriptor` entry.

Interfaces

Definitions of interfaces are accumulated to the hash `$build->{interfaces}`, with the key of each entry being the interfaces name. Each interface structure has the form:

```
{
 name           => <name of the interface>
 comment        => <a description of the interface>
 intrinsic      => <the intrinsic type of the function (or "void" for a subroutine)>
 data           => <variable list containing all arguments for this interface>
```

Functions

Definitions of functions are accumulated either to the list `$build->{'functions'}` or are included as the `descriptor` in a derived type structure (this is the prefered method for functions that *are* bound to a derived type; see §15.1.2). Each function structure has the form:

```
{
 type        => <the type of function>
 name        => <function name>
 description => <LaTeX-syntax description of the function>
 modules     => <list of names of modules required by the function> [optional]
 variables   => <list of variables required by the function> [optional]
 content     => <the code of the function (excluding opener, closer, and variable definitions)>
}
```

Module-scope Variables

Any module-scope variables can be pushed to the array `{$build->{'variables'}}`, using the usual definition format described in §15.1.1.

15.2. Galacticus Preprocessor Directives

Galacticus has its own preprocessor for Fortran source files. This preprocesses parses each source file into an internal tree representation, performs various manipulations on that tree, and then outputs the preprocessed file for compilation. The preprocessor is used to automate and standardize many common tasks, through the inclusion of directives into the source code. Directives are specified in comment lines beginning `!#`, and are written in XML. The remainder of this section describes the various preprocessor functionalities, and gives examples of their usage.

15.2.1. Source Code Introspection

The source code introspection functionality allows automated generation of information about the source code. Specifically:

- The directive `{introspection:location}` in source code will be replaced with a character string giving a backtrace of the current location in the code, including any function, module, and file (including line number).

15.2.2. Function Attributes

Galacticus allows the specification of attributes for functions which alter the way the compiler treats them. Function attributes are specified as:

```
!$GLC function attributes {attributes} :: {functionNames}
```

where `{attributes}` is a space-separated list of attributes, and `{functionNames}` is a space-separated list of functions to apply these functions to. Function attribute directives may appear anywhere in a file containing the named function, but it is good practice to locate them immediately before the function.

Currently, the supported attributes are:

`unused` The function is marked as being *possibly* unused. Compiler warnings about unused functions will be suppressed for this function.

15.2.3. Source Digest

The `sourceDigest` directive will generate an MD5 hash hash of the source code of the file in which the directive is placed, along with the source code of any files upon which it depends. This can be useful in

generating unique labels (e.g. to use as suffixes in file names) which automatically update if the source code is modified. To generate a source digest simply use:

```
!# <sourceDigest name="mySourceDigest"/>
```

A source digest will be generated and stored as a `character(len=22)` variable called `mySourceDigest`.

15.2.4. Object Builder

When constructing instances of a class from a provided parameter set, a common pattern is to need to construct other objects based on those parameters, which will be used by the instance. For example, a transfer function class might require a cosmological parameters object for its operation. In such cases, we often want to use the default instance of the required class unless a different instance is explicitly specified. The `objectBuilder` directive automates this process.

As an example, the following constructor requires an instance of the `cosmologyParameters` class, which is passes to an internal constructor:

```
function myConstructorParameters(parameters)
  use Input_Parameters2
  implicit none
  type(myClass                    )                :: myConstructorParameters
  type(inputParameters            ), intent(in    ) :: parameters
  class(cosmologyParametersClass), pointer         :: cosmologyParameters_

  !# <objectBuilder class="cosmologyParameters" name="cosmologyParameters_" source="para
  myConstructorParameters=myConstructorInternal(cosmologyParameters_)
  return
end function myConstructorParameters
```

The `objectBuilder` directive will assign a member of the class specified by the `class` attribute to the variable specified by the `name` attribute. If the parameter set specified by the `parameters` attribute contains an explicit definition of the relevant class, that definition will be used to construct the instance. Otherwise, the parent parameter set will be checked for a definition of the relevant class, and so on. If no definition is found when the root parameter set is found the default instance will be used. Note that objects created by an `objectBuilder` directive are directly associated with the element in the input parameters XML document from which they were created. Therefore, if a later `objectBuilder` requires the object from that same XML element, it will reuse the one previously created.

The `objectBuilder` directive by default searches for a parameter named `{class}Method` where `{class}` is the value of the `class` attribute in the directive. An alternative name may be specified via the addition of a `parameterName` attribute.

In cases where an explicit `parameterName` attribute is given, it is possible to specify an explicit default for the object if no such named parameter is found. (Where no explicit `parameterName` attribute is given the global default of the class is used.) A default is specified by adding a `default` element to the directive, which should contain default specification for the object (and any subobjects) in the usual format. For example:

```
!# <objectBuilder class="massDistribution" parameterName="diskMassDistribution" name="diskMassDistribut
!#  <default>
!#   <diskMassDistribution value="exponentialDisk">
!#    <dimensionless value="true"/>
!#   </diskMassDistribution>
!#  </default>
!# </objectBuilder>
```

15.2.5. Object Destructor

This directive can (and should) be used to destroy objects built by the `objectBuilder` directive. The `objectDestructor` directive automates the process of deciding if these objects should be destroyed (or merely have pointers to them nullified). As an example, the following destructor destroys two associated objects:

```
 subroutine simpleDestructor(self)
   implicit none
   type(powerSpectrumPrimordialTransferredSimple), intent(inout) :: self

   !# <objectDestructor name="self%transferFunction_"         />
   !# <objectDestructor name="self%powerSpectrumPrimordial_"/>
  return
 end subroutine simpleDestructor
```

15.2.6. Constructor Assignments

A common requirement in object constructors is to assign the values of arguments to the constructor to corresponding entries in the object. The `constructorAssign` directive performs this assignment for a list of comma-separated variables. For example:

```
 function stellarMassConstructorInternal(massThreshold)
   implicit none
   type             (galacticFilterStellarMass)                 :: stellarMassConstructorIn
   double precision                           , intent(in    ) :: massThreshold
   !# <constructorAssign variables="massThreshold"/>
   return
 end function stellarMassConstructorInternal
```

will cause the value of the `massThreshold` argument to `stellarMassConstructorInternal%massThreshold`. If an argument name is prefixed with `*` in the variables list, pointer assignment is used instead of standard assignment.

15.2.7. State Storing

Galacticus supports storing its internal state to file to allow restarts (see §2.3.2). Code to store and restore the internal state of objects of a given class can be generated automatically through use of the `stateStorable` directive. An example is:

```
!# <stateStorable class="table">
!#  <table1DGeneric>
!#   <restoreTo variables="reset" state=".true."/>
!#   <exclude variables="staticData"/>
!#  </table1DGeneric>
!#  <table2DLinLinLin>
!#   <restoreTo variables="resetX, resetY" state=".true."/>
!#  </table2DLinLinLin>
!# </stateStorable>
```

This specifies that the `table` class (and all child classes) can and should be stored to file as part of the representation of the internal state. Code to store and restore all data associated with any object of this

class (as well as restoring polymorphic objects to the correct type) will be generated. If certain variables of the classs or subclass should be restored to specific values this can be specified through a `restoreTo` element placed within an element with the name of the class or subclass (e.g. the `table1DGeneric` in the above example). The `restoreTo` element should specify a comma-separated list of one or more variables to set in its `variables` attribute, and the state to which they should be restored in its `state` attribute. Any variables which should be excluded from state store/restore (e.g. if their values are known to be determined statically at construction) can be specified via a `exclude` element—a list of variables to exclude should be given as a comma-separated list in its `variables` attribute.

15.2.8. Conditional Call

In some instances it is useful to be able to call a function with different combinations of optional arguments depending on certain conditions. (For example, if some combinations of optional arguments are mutually exclusive.) This can be achieved using the `conditionalCall` directive. An example is:

```
!# <conditionalCall>
!#  <call>self=massDistributionBetaProfile(beta{conditions})</call>
!#  <argument name="densityNormalization" value="densityNormalization" parameterPresent="parameters"/>
!#  <argument name="mass"                 value="mass"                 parameterPresent="parameters"/>
!#  <argument name="outerRadius"          value="outerRadius"          parameterPresent="parameters"/>
!#  <argument name="coreRadius"           value="coreRadius"           parameterPresent="parameters"/>
!#  <argument name="dimensionless"        value="dimensionless"        parameterPresent="parameters"/>
!# </conditionalCall>
!# <inputParametersValidate source="parameters"/>
```

The `call` element specifies the function call, and contains the special sequence `{conditions}` which will be replaced with the conditionally-present arguments. One or more `argument` elements should specify the various arguments which should be included in the call. For each such element the `name` attribute specifies the name of the dummy argument in the called function, the `value` attribute specifies the value (or variables) to pass this this dummy argument. A condition for inclusion of the argument must also be specified. In the above, the special `parameterPresent` condition is used. The argument will be included in the call if a parameter with a name matching the `name` attribute exists in the parameter set named in the `parameterPresent` attribute. Alternatively a `condition` attribute can be given. An argument is included in the call if the expression given in the `condition` attribute evaluates to true.

Code will be generated to call the function with all possible combinations of arguments.

15.2.9. Optional Arguments

Fortran supports optional arguments to functions, but does not provide for a default value if those arguments are not present. The `optionalArgument` directive allows a default value to be specified. In the following example, a default value is defined for the `units` argument:

```
double precision function simpleHubbleConstant(self,units)
  implicit none
  class  (cosmologyParametersSimple), intent(inout)           :: self
  integer                           , intent(in   ), optional :: units
  !# <optionalArgument name="units" defaultsTo="hubbleUnitsStandard" />

  select case (units_)
  case (hubbleUnitsStandard)
     ! Return the value using the default units.
```

```
    case ....
       ! Return the value using some other units.
    end select
    return
  end function simpleHubbleConstant
```

The `optionalArgument` directive should appear after variable declarations and before any attempt to use the optional argument, and should have two attributes, `name` and `defaultsTo` which give the name of the argument variable and its default value respectively. The preprocessor will add a new variable with the same name plus an underscore suffix, and will ensure that it is initialized to the default value if the optional variable is not present, otherwise setting it to the value of the optional variable.

Note that for optional arguments that are `intent(out)` or `intent(inout)` the preprocessor currently *does not* ensure that the value of the new variable is copied back to the argument prior to exit from the function.

15.2.10. Enumerations

The `enumeration` directive allows specification of an enumeration (a set of labels), and (optionally) functions to decode such a label from user input. The following example illustrates this usage:

```
module Cosmology_Parameters

  !# <enumeration>
  !#  <name>hubbleUnits</name>
  !#  <description>Specifies the units for the Hubble constant.</description>
  !#  <visibility>public</visbility>
  !#  <validator>yes</validator>
  !#  <encodeFunction>yes</encodeFunction>
  !#  <entry label="standard" />
  !#  <entry label="time"     />
  !#  <entry label="littleH"  />
  !# </enumeration>

contains

subroutine Test_Enumeration()
    use ISO_Varying_String
    implicit none
    class(cosmologyParametersClass), pointer :: cosmologyParameters_
    cosmologyParameters_ => cosmologyParameters()
    write (0,*) "Enumeration contains ",hubbleUnitsCount," entries from ",hubbleUnitsMin,"
    write (0,*) "Hubble constant in little-h units is: ",cosmologyParameters_%HubbleConstan
    if (enumerationHubbleUnitsEncode('hubbleUnitsStandard') == hubbleUnitsStandard) then
      write (0,*) "Enumeration decoding succeeded"
    else
      write (0,*) "Enumeration decoding failed"
    end if
    if (enumerationHubbleUnitsEncode('standard',includesPrefix=.false.) == hubbleUnitsStand
      write (0,*) "Enumeration decoding succeeded"
    else
      write (0,*) "Enumeration decoding failed"
```

```
    end if
    write (0,*) "Name from time value is '",char(enumerationHubbleUnitsDecode(hubbleUnits
  return
end subroutine Test_Enumeration

end module Cosmology_Parameters
```

Enumerations must be defined in the declaration section of a `module`. The encoding and decoding functions will only be generated if the `encode` element is present and has content `yes`. The enumeration variables are given `public` visibility by default—this can be overridden using the `visibility` element. If the `validator` element is present and set to `yes` then a function is created which will return true if the given value is a valid one for the enumeration. Additionally, if the `validator` element is present and set to `yes` variables are created giving a count of the number of entries in the enumeration, along with the minimum and maximum values in the enumeration. Note that the `description` element is used to generate an entry for the enumeration in the document, and so should be written in LaTeX syntax.

15.2.11. Input Parameters

The `inputParameter` directive reads an input parameter and assigns the appropriate value to the given variable. `inputParameter` directives must occur within the main body of a function, subroutine, or program. A default value can be specified if desired. The following example illustrates this usage:

```
subroutine simpleParametersRead()
  implicit none
  double precision :: hubbleConstant
  !# <inputParameter>
  !#   <name>HubbleConstant</name>
  !#   <source>myParameters</source>
  !#   <variable>hubbleConstant</variable>
  !#   <defaultValue>69.7d0</defaultValue>
  !#   <defaultSource>(\citealt{hinshaw_nine-year_2012}; CMB$+H_0+$BAO)</defaultSource>
  !#   <description>The present day value of the Hubble parameter in units of km/s/Mpc.</
  !#   <type>real</type>
  !#   <cardinality>0..1</cardinality>
  !# </inputParameter>
  if (hubbleConstant < 0.0d0) write (0,*) "The universe is collapsing!"
  return
end subroutine simpleParametersRead
```

In this case, the value of the `HubbleConstant` parameter is assigned to the `hubbleConstant` variable, with a default of 69.7 if no value was specified in the input parameter file. If the `source` element is present, the parameter will be read from the named `inputParameters` set, otherwise the parameter will be read from the top-level of the parameters file. The `defaultSource`, `<description>The`, `type`, and `cardinality` elements are used only for adding an entry for the input parameter to the documentation, and so should be written in LaTeX syntax.

It is also possible to specify a set of parameter which iterate over names defined by other directives. The following example would read one parameter named "`fileNameForXXXXXXIMF`" where "`XXXXXX`" equals the `name` element each `imfRegisterName` dircetive:

```
!# <inputParameter>
!#   <iterator>fileNameFor(#imfRegisterName->name)IMF</iterator>
!#   <source>parameters</source>
```

```
!#    <variable>fileNames(IMF_Index("$1"))</variable>
!#    <defaultValue>Galacticus_Input_Path()//"data/SSP_Spectra_imf$1.hdf5"</defaultValue
!#    <description>The name of the file of stellar populations to use for the named \gls
!#    <type>string</type>
!#    <cardinality>0..1</cardinality>
!# </inputParameter>
```

15.2.12. Input Parameter Lists

The `inputParameterList` directive will construct a `varying_string` array containing the names of all input parameters which are defined in the unit in which the directive appears. The name of the array is specified by the `label` attribute of the `inputParameterList` directive. If a `source` attribute is specified in the directive then only parameters being read from the named variable will be included in the list, otherwise any parameters read will be included. Such a list can be used to validate the names of parameters passed to a function for example.

15.2.13. Function Classes

Most[1] of the internal functionality within Galacticus is provided by "function classes". These are classes (in the object oriented sense) which model some particular physical entity or concept (e.g. the underlying cosmological model) and provide one or more functions associated with that entity or concept. A default implementation of each function class can be selected at run-time, allowing for simple user-defined control of model behavior. A function class is specified by a `functionClass` directive, together with one or more implementations of the function class specified by their own directives.

An example of a function class directive, which defines a class for cosmological parameters (which in this case, for simplicity, consists of just the Hubble constant) is given below:

```
!# <functionClass>
!#  <name>cosmologyParameters</name>
!#  <descriptiveName>Cosmological Parameters</descriptiveName>
!#  <description>Object providing various cosmological parameters.</description>
!#  <default>simple</default>
!#  <defaultThreadPrivate>no</defaultThreadPrivate>
!#  <stateful>no</stateful>
!#  <calculationReset>no</calculationReset>
!#  <method name="HubbleConstant" >
!#   <description>Return the Hubble constant at the present day. The optional {\normalfo
!#   <type>double precision</type>
!#   <pass>yes</pass>
!#   <argument>integer, intent(in    ), optional :: units</argument>
!#  </method>
!# </functionClass>
```

The directive should contain the following elements:

`name` The name of this function class.

`descriptiveName` A descriptive name for the function class, suitable for inclusion in the documentation.

`description` A description of the purpose of this function class. This description will be included into the documentation so should be written in LaTeX syntax.

[1] At this time the Galacticus code base is being transitioned to use this approach.

`default` The default implementation to use for this function class if no choice is made in the input parameter file.

`defaultThreadPrivate` *(optional)* If present and set to `yes` then the default implementation of this function class will be made OpenMP thread private. Otherwise, the default implementation is shared between threads. A thread private default implementation can be useful if the function class may need to generate look-up tables unique to each thread on the fly for example.

`calculationReset` *(optional)* If present and set to `yes` then the default implementation of the function class is assumed to possibly want to reset its calculations when the active node changes (see §16.4.3). In this case, an additional method is generated for the function class: `calculationReset` with interface:

```
subroutine calculationReset(self,thisNode)
  class  (functionClassBaseName), intent(inout)           :: self
  type   (treeNode             ), intent(inout), pointer :: thisNode
end subroutine calculationReset
```

This method has a null implementation for the base class of the function class, but can be overridden to reset calculations of any given implementation.

`method` Each `method` element defines a method which the function class will support, the name of which is given by a `name` attribute. The method definition must contain the following elements:

`description` A description of this method (in LaTeX syntax) suitable for inclusion into the documentation.

`type` The type of the function (e.g. `double precision`; use `void` for a subroutine).

`pass` If `yes` pass the object that the method was called on as the first argument.

`argument` *(optional)* Zero or more declarations (in standard Fortran syntax) for the method arguments (there is no need to specify the declaration for the object upon which the method was called in the case where this object is passed to the method function).

Implementations of this function class must be declared with a directive having the same name as the function class (i.e. `cosmologyParameters` in the example above). The directive must give the name of the implementation as an attribute, and a description of the implementation suitable for inclusion into the documentation. Each implementation should be placed in a separate file—the preprocessor will find these files and merge the implementations and function class definition into a single file for compilation. Each implementation should declare a class which extends the basic function class, constructor interfaces, and any module-scope data required by the class. The implementation should also define all necessary functions required by the class (separated from the declarations by a `contains` keyword). An example is given below:

```
!# <cosmologyParameters name="cosmologyParametersSimple">
!#  <description>Provides the Hubble constant: $H_0$.</description>
!# </cosmologyParameters>
type, extends(cosmologyParametersClass) :: cosmologyParametersSimple
   private
   double precision :: HubbleConstantValue
 contains
   final     ::                    simpleDestructor
   procedure :: HubbleConstant  => simpleHubbleConstant
end type cosmologyParametersSimple
```

```
  interface cosmologyParametersSimple
     module procedure simpleDefaultConstructor
     module procedure simpleConstructor
  end interface cosmologyParametersSimple

contains

  function simpleDefaultConstructor()
    implicit none
    type(cosmologyParametersSimple) :: simpleDefaultConstructor

    ! Construct an instance of this class using a value of the Hubble constant read from th
    !# <inputParameter>
    !#   <name>H_0</name>
    !#   <variable>simpleDefaultConstructor%HubbleConstantValue</variable>
    !#   <defaultValue>69.7d0</defaultValue>
    !#   <defaultSource>(\citealt{hinshaw_nine-year_2012}; CMB$+H_0+$BAO)</defaultSource>
    !#   <description>The present day value of the Hubble parameter in units of km/s/Mpc.</
    !#   <type>real</type>
    !#   <cardinality>0..1</cardinality>
    !# </inputParameter>
    return
  end function simpleDefaultConstructor

  function simpleConstructor(HubbleConstant)
    implicit none
    type            (cosmologyParametersSimple)                :: simpleConstructor
    double precision                           , intent(in    ) :: HubbleConstant

    ! Construct an instance of this class using a value of the Hubble constant provided di
    simpleConstructor%HubbleConstantValue=HubbleConstant
    return
  end function simpleConstructor

  elemental subroutine simpleDestructor(self)
    implicit none
    type(cosmologyParametersSimple), intent(inout) :: self

    ! Do any clean-up required by this class when an instance goes out-of-scope.
    return
  end subroutine simpleDestructor

  double precision function simpleHubbleConstant(self,units)
    implicit none
    class  (cosmologyParametersSimple), intent(inout)           :: self
    integer                           , intent(in    ), optional :: units

    ! Do whatever is necessary to return the Hubble constant in the appropriate units.
```

```
    return
  end function simpleHubbleConstant
```

In the above example, we define a "simple" implementation of the cosmologyParameters class. Key points are:

Name: The name should always be prefixed with the function class name. In this case, we have a `simple` implementation of the `cosmologyParameters` function class, and so our name is `cosmologyParametersSimple`.

Extends: The base class for the function class is always the function class name suffixed with `Class`, in this case `cosmologyParametersClass`. Implementations must always be extensions of either this base class, or of another implementation.

Procedures: The implementation must define procedures for all methods of the function class, *except* for where a method specified a `code` element in the function class directive (in which case a procedure for the method may still be optionally defined). Specification of a `final` function is encouraged.

Constructors: The implementation must specify at least one constructor, which takes no arguments (usually known as the default constructor). This constructor must create an instance of the implementation, setting any parameters from the input parameter file as necessary. Additional constructors may be defined as required.

Procedures: All required procedures (including constructors and destructors) should be given after a line containing the `contains` keyword. GALACTICUS coding policy is that all procedures associated with an implementation should be prefixed with the implementation name, `simple` in this case.

Functionality to store and restore the state (see §2.3.2) of classes built via a `functionClass` directive are automatically built. If variables of a given implementation should be restored to a specific state, this can be specified by adding a `restoreTo` element to the directive declaring the implementation. The `restoreTo` element should specify a comma-separated list of one or more variables to set in its `variables` attribute, and the state to which they should be restored in its `state` attribute. Any variables which should be excluded from state store/restore (e.g. if their values are known to be determined statically at construction) can be specified via a `exclude` element—a list of variables to exclude should be given as a comma-separated list in its `variables` attribute.

15.2.14. Generic Programming

The preprocessor supports generic programming by allowing generic types to be defined, which are automatically expanded to a set of specific types. Significant flexibility is provided to allow control over how each specific type is handled. A generic type is specific via a `generic` directive such as:

```
  !# <generic identifier="Type">
  !#  <instance label="Logical"          intrinsic="logical"
outputConverter="regEx|(.*)|char($1)|"/>
  !#  <instance label="Integer"          intrinsic="integer"
outputConverter="regEx|(.*)|$1|"       />
  !#  <instance label="Double"           intrinsic="double precision"
outputConverter="regEx|(.*)|$1|"       />
  !#  <instance label="LogicalRank1"     intrinsic="logical          , dimension(:)" outputC
  !#  <instance label="IntegerRank1"     intrinsic="integer          , dimension(:)" outputC
/>
  !#  <instance label="DoubleRank1"      intrinsic="double precision , dimension(:)" outputC
/>
  !# </generic>
```

The above defines a generic type, which will be identified using the label "`Type`". The directive contains several `instance` elements, each of which specifies a specific type which should be implemented for the generic type. Each instance can contain an arbitrary number of attributes which specify strings or regular expressions which will be used to construct the specific implementation.

A generic directive applies to the entire unit within which it is scoped. The preprocessor will examine every element within that unit. If a generic tag (see below) is found in the opening of any subunit, that entire subunit is copied once for each instance, and any generic tags replaced with the appropriate content from the `instance` element. Where a generic tag is found in a non-opening line (and that line is not contained within a subunit whose opener *does* contain a generci tag), the line itself is replicated in the same way.

An example of the usage of generic tags using the above generic directive is:

```
type :: exampleType
   private
   .
   .
   .
 contains
   final     ::         exampleTypeDestroy
   procedure ::         exampleTypeSet{Type|label}
   generic   :: set => exampleTypeSet{Type|label}
end type exampleType

contains

subroutine exampleTypeSet{Type|label}(self,setValue)
  implicit none
  class           (exampleType), intent(in   ) :: self
  {Type|intrinsic}             , intent(in   ) :: setValue

  {Type|match|^Logical|! Do something to set a logical value.|! Do something different to s
  write (0,*) "Value is: ",{Type|outputConverter|setValue}
end subroutine exampleTypeSet{Type|label}
```

In this example, the `exampleType` class is defined to have a generic `set` method. The presence of the `{Type@|@label}` generic tag will cause those lines to be replicated with the tag replaced by the content of the `label` attribute of each instance of the generic type. In the contained subroutine, a generic tag appears in the opener. As such, the entire subroutine will be replicated once for each instance of the generic type, and the generic tags replaced as appropriate.

When a generic instance attribute begins with `regEx`, matching generic tags are handled differently. In particular, a match-and-replace regular expression is applied to the third element of the generic tag (elements are separated by broken vertical bar characters). The match and replace components of the regular expression are defined in the instance attribute, once again separated by broken vertical bars.

Finally, the special generic tag `match` acts as a ternary operator. If the regular expression specified in the third element matches the `label` attribute of a specific instance, the generic tag is replaced with its fourth element, otherwise it is replaced with its fifth element.

15.3. Numerical Tools

Galacticus provides a variety of tools to solve basic numerical problems. These can be found in files `source/numerical.*`. Galacticus makes use of the GNU Scientific Library for many of these tools, but typically provides a higher-level wrapper around those functions, providing a cleaner interface and, in some cases, additional functionality.

15.3.1. Finding Roots of Equations

Tools for solving equations of the form $f(x) = 0$ are provided by the `rootFinder` object (available via the `Root_Finder` module). Typical use of this object is as follows:

```
! Import the module.
use Root_Finder
...
! Create a rootFinder object - make it OpenMP threadprivate so it can be used
! simultaneously by all threads.
type(rootFinder), save :: finder
!$omp threadprivate(finder)
...
! Check if our root finder has been initialized.
if (.not.finder%isInitialized()) then
  ! Specify the function that evaluates f(x).
  call finder%rootFunction    (myRootFunction                          )
  ! Specify the type of root-finding algorithm - this is optional (Brent's
  ! method will be used by default).
  call finder%type            (FGSL_Root_fSolver_Brent                 )
  ! Specify the tolerances to use in finding the root. Both arguments are
  !optional - values of 1.0d-10 will be used for both absolute and relative
  ! tolerance by default.
  call finder%tolerance       (toleranceAbsolute,toleranceRelative)
  ! Specify how the initially provided range can be expanded to bracket the
  ! root. This is optional - if not provided no range expansion will be attempted.
  call finder%rangeExpand                                              &
       & (                                                             &
       &  rangeExpandDownward          =0.5d0                        , &
       &  rangeExpandUpward            =2.0d0                        , &
       &  rangeExpandType              =rangeExpandMultiplicative    , &
       &  rangeDownwardLimit           =1.0d-3                       , &
       &  rangeUpwardLimit             =1.0d+3                       , &
       &  rangeExpandDownwardSignExpect=rangeExpandSignExpectPositive, &
       &  rangeExpandUpwardSignExpect  =rangeExpandSignExpectNegative
       & )
end if
x=finder%find(rootGuess=1.0d0)
.
.
.
double precision function myRootFunction(x)
  implicit none
```

```
   double precision, intent(in   ) :: x
   ...
   return
end function myRootFunction
```

The above example begins by importing the `Root_Finder` module and then creating a `rootFinder` object called `finder`. This is made OpenMP `threadprivate` so that it may be used simultaneously by all threads. The first step is to initialize `finder`—the `isInitialized` method tells us if this has already happened. The most important step is to specify the function that will evaluate $f(x)$. This is done via the `rootFunction` method—once done, the `rootFinder` object is marked as initialized (and the `isInitialized` method will return `true`). All other initialization steps are optional. In this example, we use the `type` method to specify that the `Brent` algorithm should be used for root finding. Any valid GSL-supported root finding algorithm can be used. We then use the `tolerance` method to specify both the absolute and relative tolerances in the x variable that must be attained to declare the root to be found. Both arguments are optional—default values of 10^{-10} will be used if either tolerance is not specified.

The final step of initialization is to call the `rangeExpand` method. This specifies how the initial guessed value or range for x should be expanded to bracket the root. If you plan to always specify an initial range, and know that it will always bracket the root, you do not need to specify how the range should be expanded. In this case we've specified that range expansion is multiplicative—that is, the lower and upper values of x defining the range will be multiplied by fixed factors until the root is bracketed—via the `rangeExpandType=rangeExpandMultiplicative` option. Alternatively, additive expansion is possible using `rangeExpandType=rangeExpandAdditive`. The factors by which to multiply the lower and upper bounds of the range (or the factor to add in the case of additive expansion) are specified by the `rangeExpandDownward` and `rangeExpandUpward` options. Iit is possible to specify absolute lower/upper limits to the range via the `rangeDownwardLimit` and `rangeUpwardLimit` options. The range will not be expanded beyond these limits—if the root cannot be bracketed without exceeding these limits an error condition will occur. Finally, it is possible to indicate the expected sign of $f(x)$ at the lower and/or upper limits via the `rangeExpandDownwardSignExpect` and `rangeExpandUpwardSignExpect` options. Valid settings are `rangeExpandSignExpectNegative`, `rangeExpandSignExpectPositive`, and `rangeExpandSignExpectNone` (the default—implying that there is no expectation for the sign). If the sign of $f(x)$ is specified, then range expansion will stop once the expected sign is found. This can often improve efficiency, by allowing the range expander to expand the range in only one direction, resulting in a narrower range in which to search for the root.

Finally, we use the `find` method to return the value of the root. The first argument to `find` is the name of the function that evaluates $f(x)$. Additionally, we must supply either `rootGuess` (a scalar value guess to use as the initial value for both the lower and upper values of the range—note that range expansion must be allowed in this case), or `rootRange` (a two-element array to use as the initial lower and upper values of the range bracketing the root).

The function evaluating $f(x)$ must have a form compatible with that shown for `myRootFunction` in the above example.

15.4. Computation Dependencies and Data Files

In many situations, some module in Galacticus might want to perform a calculation and then store the results to a file so that they can be reused later. A good example is the `CAMB` transfer function method (see §12.6.5), which computes a transfer function using CAMB and stores this function in a file so that it can be re-read next time, avoiding the need to recompute the transfer function. A problem arises in such cases as the calculation may depend on the values of parameters (in our example, the transfer function will depend on cosmological parameters for example). We would like to record which parameter values this calculation refers to, perhaps encoding these into the file name, so that we can reuse these data in a

future run only if the parameter values are unchanged. Given the modular nature of Galacticus it is impossible to know in advance which parameters will be relevant (e.g. does the cosmological parameter implementation have a parameter that describes a time varying equation of state for dark energy?).

To addres this problem, Galacticus provides a mechanism to generate a unique descriptor for a given object. This descriptor encodes the parameter used to construct the object, and recursively includes the parameters used to construct any other object which is composited. A long-form (human readable) descriptor is returned by the `descriptor` method associated with all `functionClass` objects. Additionally, the `hashedDescriptor` method will return an MD5 hash of the descriptor, which will be unique (up to collisions) and can be used to idetify the object both internally and, for example, when used as a suffix to file names. If the optional `includeSourceDigest` argument is set to true in the `hashedDescriptor` method then the hashed descriptor will include a hash of the source code of the object (and all composited objects) such that the descriptor will change should the source code be changed.

15.5. Optimization

In designing Galacticus, we opted for simplicity and clarity over speed. However, there are numerous parts of the code where optimization has been performed without a significant loss of clarity. In this section we discuss some of the techniques used.

15.5.1. Unique IDs and Stored Properties

Frequently, a given property of a node may be required in many different aspects of the calculation. For example, the dark matter halo virial radius is used extensively in several distinct calculations within Galacticus. Frequently such calculations are performed for the same node, with the same properties several times[2]. Obviously this is inefficient. It can be advantageous in such cases to store the result of a calculation and, if the function is called again with the same unchanged node to simply return the stored value. Galacticus facilitates this by two features.

The first feature is the "unique ID"—an integer number assigned to each node in Galacticus and which uniquely identifies a node (i.e. no two nodes processed in a Galacticus run will have the same unique ID). This number, which can be retrieved using the `uniqueID` property of a tree node, can be recorded each time a function is called. If called again for a node with the same unique ID as the previous call, the function can simply return the same answer as on the previous call.

The second feature accounts for the fact that the properties of a node will change, so even if a function is called on a node with the same unique ID it may occasionally need to recompute its result. Galacticus provides a calculation reset task (see §16.4.3). All such tasks are performed just prior to the computation of derivatives for a node being evolved. A function can register a calculation reset task and use it to flag that it must update its calculations even if called again with the same node.

15.6. Global Functions

In very exceptional circumstances it is necessary to subvert the module hierarchy used by Galacticus to permit one module to call a function in a higher level module[3]. Examples of where this approach is necessary usually involve initial bootstrapping (i.e. to establish halo density contrasts, which requires knowledge of the halo density profile, which in turn requires knowledge of the halo density contrast...).

[2] For example, Galacticus's ODE solver will fix the properties of a node and then request that derivatives of all properties be computed. Some functions will then be called multiple times for the same node with unchanged properties.

[3] This usually arises because circular dependencies would arise if the called function were placed in a lower level module.

Galacticus provides for global functions which facilitate this—specifically, it is possible to generate function pointers to higher level functions which are accessible via a very low-level module. To create a globally callable copy of a function use add the follow prior to the function definition:

```
!# <functionGlobal>
!#  <unitName>myFunction</unitName>
!#  <type>double precision</type>
!#  <arguments>double precision , intent(in   ) :: mass, time</arguments>
!# </functionGlobal>
```

Here, `myFunction` is the name of the function to make global, while the `type` and `arguments` (of which there may be more than one) elements are used to generate a suitable interface for the function. At run-time, a pointer to this function is then available from the `Functions_Global` module, named `myFunction_`. Note that `Functions_Global_Set` provided by the `Functions_Global_Utilities` module must be called once to initialize these global function pointers prior to their use.

15.7. Galacticus Metadata

Galacticus can collect metadata on its own activity. This is useful for profiling the code for example.

15.7.1. OpenMP Critical Section Wait Times

Galacticus makes use of OpenMP for parallel operation. OpenMP `critical` sections are used throughout to limit access to parts of the code which must be executed in serial. Threads will block at each `critical` section if another thread is currently within it. Galacticus can profile the amount of time spent waiting at each named OpenMP `critical` section across all threads. To enable this profiling Galacticus should be compiled with `-DOMPPROFILE` added to the compile options (in `GALACTICUS_FCFLAGS`). This will cause profiling instructions to be added to the source code prior to compilation. When this instrumented executable is run an `metaData/openMP/` group will be added to the output file. This group contains two datasets, `criticalSectionNames` and `criticalSectionWaitTimes`. The first lists the names of all named OpenMP `critical` sections, while the second lists the total number of seconds (across all threads) spent waiting at each section. A script is provided to analyze this metadata:

```
./scripts/aux/openMPCriticalWaitProfile.pl <modelFileName>
```

This script will analyze the OpenMP `critical` section wait time metadata in the named file, reporting the total time spent waiting at critical sections followed by a rank ordered list of the top ten sections by wait time. This can be useful for assessing whether optimization might help to reduce OpenMP `critical` section wait times.

15.8. Objects

15.8.1. Enumerations

Enumerations are used to communicate options to many functions in Galacticus. All available enumerations, along with their members, are described below.

accretionMode

Description: Enumeration of accretion modes for the accrtionHalo class.
Provided by: module Accretion_Halos
Members: accretionModeTotal
accretionModeHot
accretionModeCold

adafEnergy

Description: Type of energy model to use for ADAFs.
Members: adafEnergyPureADAF
adafEnergyISCO

adafFieldEnhancement

Description: Type of field enhancement model to use for ADAFs.
Members: adafFieldEnhancementExponential
adafFieldEnhancementLinear

adafRadiativeEfficiencyType

Description: Type of radiative efficiency model to use for ADAFs.
Members: adafRadiativeEfficiencyTypeFixed
adafRadiativeEfficiencyTypeThinDisk

adafTable

Description: Enumeration of ADAF look-up tables.
Members: adafTablePowerJet
adafTableRateSpinUp

adafViscosity

Description: Type of viscosity model to use for ADAFs.
Members: adafViscosityFit
adafViscosityFixed

adjustElements

Description: Used to specify how elements should be adjusted when the metallicity of an abundances object is changed.
Provided by: module Abundances_Structure
Members: adjustElementsNone
adjustElementsReset
adjustElementsUpdate

angularMomentumSource

Description: Enumeration specifying the origin of angular momentum of cooling gas in the constant rotation class.
Members: angularMomentumSourceDarkMatter
angularMomentumSourceHotGas

bryanNorman1998Fit

Description: Specifies fit type for Bryan and Norman [1998] virial density contrast.
Members: `bryanNorman1998FitFlatUniverse`
`bryanNorman1998FitZeroLambda`

cambSpecies

Description: Particle species in CAMB.
Provided by: `module Interfaces_CAMB`
Members: `cambSpeciesDarkMatter`
`cambSpeciesBaryons`

comparison

Description: Comparison operators.
Provided by: `module Interface_Local_Group_DB`
Members: `comparisonEquals`
`comparisonGreaterThan`
`comparisonLessThan`

component

Description: Specifies components for linear growth factor.
Provided by: `module Linear_Growth`
Members: `componentDarkMatter`
`componentBaryons`
`componentRadiation`

componentType

Description: Used to specify the component(s) to be queried in galactic structure functions.
Provided by: `module Galactic_Structure_Options`
Members: `componentTypeAll`
`componentTypeDisk`
`componentTypeSpheroid`
`componentTypeHotHalo`
`componentTypeColdHalo`
`componentTypeDarkHalo`
`componentTypeBlackHole`

coordinateSystem

Description: Used to specify the coordinate system of the input coordinates in galactic structure functions.
Provided by: `module Galactic_Structure_Options`
Members: `coordinateSystemSpherical`
`coordinateSystemCylindrical`
`coordinateSystemCartesian`

cutOffWhen

Description: Specifies whether cooling is cut off before or after the given epoch.
Members: `cutOffWhenBefore`
`cutOffWhenAfter`

darkEnergySphericalCollapseEnergyFixedAt

Description: Enumeration of radii at which the energy of a spherical top-hat perturbation in a dark energy cosmology can be considered to be fixed.
Provided by: `module Spherical_Collapse_Matter_Dark_Energy`
Members: `darkEnergySphericalCollapseEnergyFixedAtTurnaround`
`darkEnergySphericalCollapseEnergyFixedAtVirialization`

dataType

Description: Used to specify the type of data being stored in a `mergerTreeData` structure metadata entry.
Provided by: `module Merger_Tree_Data_Structure`
Members: `dataTypeNull`
`dataTypeInteger`
`dataTypeDouble`
`dataTypeText`

deadlockStatus

Description: Specifies deadlock status during merger tree evolution.
Provided by: `module Merger_Trees_Evolve_Deadlock_Status`
Members: `deadlockStatusIsNotDeadlocked`
`deadlockStatusIsReporting`
`deadlockStatusIsSuspendable`
`deadlockStatusIsDeadlocked`

destinationMerger

Description: Enumeration of possible destinations for mass in mergers.
Provided by: `module Satellite_Merging_Mass_Movements`
Members: `destinationMergerUnmoved`
`destinationMergerDisk`
`destinationMergerSpheroid`

direction

Description: Used to specify integration directions output specifiers.
Provided by: `module Galactic_Structure_Radii_Definitions`
Members: `directionRadial`
`directionLineOfSight`
`directionLineOfSightInteriorAverage`
`directionLambdaR`

duttonMaccio2014DensityContrastMethod

Description: Enumeration of density contrast methods available in the `duttonMaccio2014` dark matter halo profile concentration class.
Members: `duttonMaccio2014DensityContrastMethodVirial`
`duttonMaccio2014DensityContrastMethodMean200`

duttonMaccio2014DensityProfileMethod

Description: Enumeration of density profile methods available in the `duttonMaccio2014` dark matter halo profile concentration class.
Members: `duttonMaccio2014DensityProfileMethodNFW`
`duttonMaccio2014DensityProfileMethodEinasto`

elementType

Description: Enumeration of extracted property element types.
Members: `elementTypeInteger`
`elementTypeDouble`

excursionSetRemap

Description: Specifies whether a remapping of the barrier should apply to cases where the excursion set is used for rate calculation, non-rate calculations, or both.
Provided by: `module Excursion_Sets_Barriers`
Members: `excursionSetRemapRates`
`excursionSetRemapNonRates`
`excursionSetRemapBoth`

extrapolationType

Description: Used to specify the type of extrapolation to use when interpolating in tables.
Provided by: `module Table_Labels`
Members: `extrapolationTypeExtrapolate`
`extrapolationTypeFix`
`extrapolationTypeAbort`
`extrapolationTypeZero`
`extrapolationTypePowerLaw`

fixedDensityType

Description: Specifies reference density type for fixed virial density contrast.
Members: `fixedDensityTypeCritical`
`fixedDensityTypeMean`

galacticComponent

Description: Specifies the galactic component for emission line calculations.
Members: `galacticComponentDisk`
`galacticComponentSpheroid`

galacticusParticleEpochType

Description: Particle epoch type enumerations.
Members: galacticusParticleEpochTypeTime
galacticusParticleEpochTypeExpansionFactor
galacticusParticleEpochTypeRedshift

gordon2003Sample

Description: Enumerates the samples available in the gordon2003 dust attenutation class.
Members: gordon2003SampleSMCbar
gordon2003SampleLMC

haloMassFunctionErrorModel

Description: Used to specify the error model to use for halo mass function likelihoods.
Members: haloMassFunctionErrorModelNone
haloMassFunctionErrorModelPowerLaw
haloMassFunctionErrorModelSphericalOverdensity
haloMassFunctionErrorModelTrenti2010

haloModelGalaxyType

Description: Used to specify galaxy types in the halo model.
Provided by: module Conditional_Mass_Functions
Members: haloModelGalaxyTypeAll
haloModelGalaxyTypeCentral
haloModelGalaxyTypeSatellite

haloModelTerm

Description: Enumeration of terms in the halo model.
Provided by: module Halo_Model_Power_Spectrum_Modifiers
Members: haloModelTermOneHalo
haloModelTermTwoHalo

hubbleUnits

Description: Specifies the units for the Hubble constant.
Provided by: module Cosmology_Parameters
Members: hubbleUnitsStandard
hubbleUnitsTime
hubbleUnitsLittleH

inputParameterErrorStatus

Description: Error status codes used by the input parameters module.
Provided by: module Input_Parameters
Members: inputParameterErrorStatusSuccess
inputParameterErrorStatusNotPresent
inputParameterErrorStatusParse
inputParameterErrorStatusEmptyValue
inputParameterErrorStatusAmbiguousValue

interpolant

Description: Specifies the different interpolants for emission line calculations.
Members: `interpolantMetallicity`
`interpolantDensity`
`interpolantHydrogen`
`interpolantHelium`
`interpolantOxygen`

ionizingContinuum

Description: Specifies the ionizing continuum for emission line calculations.
Members: `ionizingContinuumHydrogen`
`ionizingContinuumHelium`
`ionizingContinuumOxygen`

klypin2015DensityContrast

Description: Enumeration of density contrasts in the `klypin2015` dark matter halo profile concentration class.
Members: `klypin2015DensityContrastFixed`
`klypin2015DensityContrastVirial`

klypin2015FittingFunction

Description: Enumeration of fitting functions in the `klypin2015` dark matter halo profile concentration class.
Members: `klypin2015FittingFunctionEqn24`
`klypin2015FittingFunctionEqn25`

klypin2015Sample

Description: Enumeration of sample choices available in the `klypin2015` dark matter halo profile concentration class.
Members: `klypin2015SamplePlanck200CritRelaxedMass`
`klypin2015SamplePlanck200CritAllMass`
`klypin2015SamplePlanck200CritRelaxedVmax`
`klypin2015SamplePlanck200CritAllVmax`
`klypin2015SamplePlanckVirialRelaxedMass`
`klypin2015SamplePlanckVirialAllMass`
`klypin2015SamplePlanckVirialRelaxedVmax`
`klypin2015SamplePlanckVirialAllVmax`
`klypin2015SampleWmap7200CritRelaxedMass`
`klypin2015SampleWmap7200CritAllMass`
`klypin2015SampleWmap7200CritRelaxedVmax`
`klypin2015SampleWmap7VirialRelaxedMass`
`klypin2015SampleWmap7VirialAllMass`
`klypin2015SampleWmap7VirialRelaxedVmax`
`klypin2015SamplePlanck200CritAllMassUni`
`klypin2015SamplePlanck200CritRelaxedMassUni`
`klypin2015SamplePlanckVirialAllMassUni`
`klypin2015SamplePlanckVirialRelaxedMassUni`

latentIntegratorType

Description: Used to specify the type of latent variable integrator to use.
Members: latentIntegratorTypeGaussKronrod
latentIntegratorTypeTrapezoidal

massDistributionSymmetry

Description: Specifies the symmetry of massDistribution objects.
Provided by: module Mass_Distributions
Members: massDistributionSymmetryNone
massDistributionSymmetryCylindrical
massDistributionSymmetrySpherical

massType

Description: Used to specify the mass type(s) to be queried in galactic structure functions.
Provided by: module Galactic_Structure_Options
Members: massTypeAll
massTypeDark
massTypeBaryonic
massTypeGalactic
massTypeGaseous
massTypeStellar
massTypeBlackHole

mergerTreeBranchingBound

Description: Upper/lower bound labels used in merger tree branching calculations.
Provided by: module Merger_Tree_Branching
Members: mergerTreeBranchingBoundLower
mergerTreeBranchingBoundUpper

mergerTreeFormat

Description: Used to specify which output format to use for merger tree data.
Provided by: module Merger_Tree_Data_Structure
Members: mergerTreeFormatGalacticus
mergerTreeFormatIrate

metaDataType

Description: Used to specify the type of metadata being stored in a mergerTreeData structure.
Provided by: module Merger_Tree_Data_Structure
Members: metaDataTypeGeneric
metaDataTypeCosmology
metaDataTypeSimulation
metaDataTypeGroupFinder
metaDataTypeTreeBuilder
metaDataTypeProvenance

metallicityType

Description: Used to specify the metallicity scale when working with `abundances` objects.
Provided by: `module Abundances_Structure`
Members: `metallicityTypeLinearByMass`
`metallicityTypeLinearByNumber`
`metallicityTypeLogarithmicByMassSolar`
`metallicityTypeLogarithmicByNumberSolar`
`metallicityTypeLinearByMassSolar`
`metallicityTypeLinearByNumberSolar`
`metallicityTypeLogarithmicByNumberSolarPlus12`

nonAnalyticSolvers

Description: Used to specify the type of solution to use when no analytic solution is available.
Provided by: `module Dark_Matter_Profiles_Generic`
Members: `nonAnalyticSolversFallThrough`
`nonAnalyticSolversNumerical`

normalize

Description: Specifies normalization options for linear growth factor.
Provided by: `module Linear_Growth`
Members: `normalizeMatterDominated`
`normalizePresentDay`

openMPThreadBinding

Description: Used to specify how hooked functions are bound to OpenMP threads.
Provided by: `module Events_Hooks`
Members: `openMPThreadBindingNone`
`openMPThreadBindingAtLevel`
`openMPThreadBindingAllLevels`

outputAnalysisCovarianceModel

Description: Output analyses covariance models.
Provided by: `module Output_Analyses_Options`
Members: `outputAnalysisCovarianceModelPoisson`
`outputAnalysisCovarianceModelBinomial`

outputAnalysisPropertyQuantity

Description: Property quantities.
Provided by: `module Output_Analyses_Options`
Members: `outputAnalysisPropertyQuantityUnknown`
`outputAnalysisPropertyQuantityMass`
`outputAnalysisPropertyQuantityLuminosity`

outputAnalysisPropertyType

Description:	Property types.
Provided by:	module Output_Analyses_Options
Members:	outputAnalysisPropertyTypeLinear outputAnalysisPropertyTypeLog10 outputAnalysisPropertyTypeMagnitude outputAnalysisPropertyTypeUnknown

particulateKernel

Description:	Options for softening kernel in particulate.
Members:	particulateKernelDelta particulateKernelPlummer particulateKernelGadget

pathType

Description:	Enumeration of various paths used by Galacticus.
Provided by:	module Galacticus_Paths
Members:	pathTypeExec pathTypeDataStatic pathTypeDataDynamic

propertyType

Description: Used to specify properties in a `mergerTreeData` structure.
Provided by: `module Merger_Tree_Data_Structure`
Members:
`propertyTypeNull`
`propertyTypeTreeIndex`
`propertyTypeNodeIndex`
`propertyTypeDescendentIndex`
`propertyTypeHostIndex`
`propertyTypeRedshift`

`propertyTypeVelocityDispersion`

pushType

Description: Cross-tree event type enumeration.
Members:
`pushTypeBranchJump`
`pushTypeSubhaloPromotion`

radiusFixed

Description: Enumerates the possible definitions of radius used by the "fixed" galactic structure solver.
Members: radiusFixedVirial
radiusFixedTurnaround

radiusType

Description: Used to specify radii types used in output specifiers.
Provided by: module Galactic_Structure_Radii_Definitions
Members: radiusTypeRadius
radiusTypeVirialRadius
radiusTypeDarkMatterScaleRadius
radiusTypeDiskRadius
radiusTypeSpheroidRadius
radiusTypeDiskHalfMassRadius
radiusTypeSpheroidHalfMassRadius
radiusTypeGalacticMassFraction
radiusTypeGalacticLightFraction

randomSampleCountType

Description: Used to specify the type of random sample count.
Members: randomSampleCountTypeFixed
randomSampleCountTypeMultiplicative

rangeExpand

Description: Used to specify the way in which the bracketing range should be expanded when searching for roots using a rootFinder object.
Provided by: module Root_Finder
Members: rangeExpandNull
rangeExpandAdditive
rangeExpandMultiplicative

rangeExpandSignExpect

Description: Used to specify the expected sign of the root function when searching for roots using a rootFinder object.
Provided by: module Root_Finder
Members: rangeExpandSignExpectNegative
rangeExpandSignExpectNone
rangeExpandSignExpectPositive

readNodeReachability

Description: Node reachability status.
Members: readNodeReachabilityUnreachable
readNodeReachabilityReachable

readSubhaloAngularMomentaMethod

Description: Subhalo angular momentum methods.
Members: `readSubhaloAngularMomentaMethodScale`
`readSubhaloAngularMomentaMethodSummation`

recombinationCase

Description: Enumeration of radiative recombination cases (A or B).
Provided by: `module Atomic_Rates_Recombination_Radiative`
Members: `recombinationCaseA`
`recombinationCaseB`

replicantAction

Description: Used to specify type of action required from the replicant method.
Members: `replicantActionCount`
`replicantActionAny`
`replicantActionInstance`

satelliteBoundMassInitializeType

Description: Specify how to initialize the bound mass of a satellite halo.
Provided by: `module Node_Component_Satellite_Orbiting`
Members: `satelliteBoundMassInitializeTypeBasicMass`
`satelliteBoundMassInitializeTypeMaximumRadius`
`satelliteBoundMassInitializeTypeDensityContrast`

satelliteStatusDiscriminator

Description: Enumeration of possible discriminators for satellite orphan status.
Members: `satelliteStatusDiscriminatorBoundMass`
`satelliteStatusDiscriminatorPosition`

sedFitDustType

Description: Used to specify the type of dust model to use in SED fitting likelihoods.
Members: `sedFitDustTypeNull`
`sedFitDustTypeCharlotFall2000`
`sedFitDustTypeCardelli1989`
`sedFitDustTypeGordon2003`
`sedFitDustTypeCalzetti2000`
`sedFitDustTypeWittGordon2000`

sedFitStartTime

Description: Used to specify the type of start time to use in SED fitting likelihoods.
Members: `sedFitStartTimeTime`
`sedFitStartTimeAge`

selection

Description: Options for selection of nodes to particulate.
Members: selectionAll
selectionHosts
selectionSatellites

setOperator

Description: Set operators.
Provided by: module Interface_Local_Group_DB
Members: setOperatorIntersection
setOperatorUnion
setOperatorRelativeComplement

snapshotSpacing

Description: Specifies the spacing of snapshots when regridding merger trees.
Members: snapshotSpacingLinear
snapshotSpacingLogarithmic
snapshotSpacingLogCriticalOverdensity
snapshotSpacingMillennium
snapshotSpacingList

spinDistributionType

Description: Used to specify the type of intrinsic spin distribution.
Members: spinDistributionTypeLogNormal
spinDistributionTypeBett2007

standardODEAlgorithm

Description: Used to specify the type of ODE algorithm to use.
Members: standardODEAlgorithmRungeKuttaCashKarp
standardODEAlgorithmRungeKuttaSecondOrder
standardODEAlgorithmRungeKutta
standardODEAlgorithmRungeKuttaFehlberg
standardODEAlgorithmRungeKuttaPrinceDormand
standardODEAlgorithmMultistepAdams
standardODEAlgorithmBulirschStoer
standardODEAlgorithmBdf

sussingBadValueTest

Description: Bad value test options.
Members: sussingBadValueTestLessThan
sussingBadValueTestGreaterThan

sussingHaloFormat

Description: Halo file formats.
Members: sussingHaloFormatOld
sussingHaloFormatNew
sussingHaloFormatAll

sussingMassOption

Description: Halo mass definitions.
Members: sussingMassOptionDefault
sussingMassOptionFoF
sussingMassOption200Mean
sussingMassOption200Crit
sussingMassOptionTopHat

tableType

Description: Enumeration of table types.
Provided by: module Tables
Members: tableTypeLinearLinear1D
tableTypeLogarithmicLinear1D

test

Description: Statuses for unit tests.
Provided by: module Unit_Tests
Members: testPassed
testFailed
testSkipped

tinker2008Parameter

Description: Enumeration of parameters for the tinker2008 halo mass function class.
Members: tinker2008ParameterA
tinker2008ParameterB
tinker2008ParameterC
tinker2008ParameterNormalization

treeBuild

Description: Enumeration of tree building status.
Members: treeBuildSuccess
treeBuildFailureTolerance
treeBuildFailureStructure
treeBuildFailureGeneric

treeStatistic

Description: Enumeration of tasks to be performed during a tree walk.
Members: treeStatisticNodeCount
treeStatisticEndNodeCount

`units`

Description: Used to specify the type of units being stored in a `mergerTreeData` structure.
Provided by: `module Merger_Tree_Data_Structure`
Members: `unitsMass`
`unitsLength`
`unitsTime`
`unitsVelocity`

`weightBy`

Description: Used to specify by which quantity to weight the results in galactic structure functions.
Provided by: `module Galactic_Structure_Options`
Members: `weightByMass`
`weightByLuminosity`

`wittGordon2000Model`

Description: Enumerates the models available in the `wittGorden2000` dust attenutation class.
Members: `wittGordon2000ModelMilkyWayShellTau3`
`wittGordon2000ModelSMCShellTau3`

`structureErrorCode`

Description: Error codes for galactic structure functions.
Provided by: `module Galactic_Structure_Options`
Members: `structureErrorCodeSuccess`
`structureErrorCodeInfinite`

15.8.2. Object Methods

The type of each method, and the type and names of its arguments are specified for each method of each object. Types are shown in red, enclosed by angle brackets, with a "`*`" indicating a pointer. A `<void>` type indicates a subroutine. Blue arrows after each argument show the argument intent: ← implies `intent(in)`, → implies `intent(out)`, and ↔ implies `intent(inout)`.

`abundances`

`<type(abundances)>` `add(<type(abundances)>` `abundances2`→`)` Add two abundances.

`<void>` `builder(<*type(node)>` `abundancesDefinition`→`)` Build an abundances object from a provided XML description.

`<void>` `deserialize(<double(:)>` `historyArray`→`)` Deserialize an abundances object from an array.

`<void>` `destroy()` Destroy an abundances object.

`<type(abundances)>` `divide(<double>` `divisor`→`)` Divide an abundance by a scalar.

`<void>` `dump()` Dump an abundances object.

`<void>` `dumpRaw(<integer>` `fileHandle`→`)` Dump an abundances object to binary.

`<double>` `heliumMassFraction()` Returns the helium fraction by mass.

<double> heliumNumberFraction() Returns the helium fraction by number.

<double> hydrogenMassFraction() Returns the hydrogen fraction by mass.

<double> hydrogenNumberFraction() Returns the hydrogen fraction by number.

<void> increment(<type(abundances)> addAbundances→) Increment an abundances object.

<logical> isZero() Return true if an abundances object is zero.

<void> massToMassFraction(<double> mass→) Converts abundance masses to mass fractions by dividing by the given mass while ensuring that fractions are in the range 0–1.

<double> metallicity(<metallicityType> [metallicityType]→) Returns the metallicity.

<void> metallicitySet(<double> metallicity→, <metallicityType> [metallicityType]→, <adjustElements> [adjustElements]→, <integer> [abundanceIndex]→) Sets the metallicity to metallicity.

<type(abundances)> multiply(<double> multiplier→) Multiply an abundance by a scalar.

<integer(c_size_t) > nonStaticSizeOf() Returns the size of any non-static components of the type.

<void> output(<integer> integerProperty↔, <integer> integerBufferCount↔, <integer(:,:)> integerBuffer↔, <integer>doubleProperty↔, <integer> doubleBufferCount↔, <double(:,:)> doubleBuffer↔, <double> time→, <integer> instance→) Store an abundances object in the output buffers.

<void> outputCount(<integer> integerPropertyCount↔, <integer> doublePropertyCount↔, <double> time→, <integer> instance→) Specify the count of an abundances object for output.

<void> outputNames(<integer> integerProperty↔, <char[*](:)> integerPropertyNames↔, <char[*](:)> integerPropertyComments↔, <double(:)> integerPropertyUnitsSI↔, <integer> doubleProperty↔, <char[*](:)> doublePropertyNames↔, <char[*](:)> doublePropertyComments↔, <double(:)> doublePropertyUnitsSI↔, <double> time→, <integer> instance→) Specify the names of abundance object properties for output.

<void> postOutput(<double> time→) Store an abundances object in the output buffers.

<void> readRaw(<integer> fileHandle→) Read an abundances object from binary.

<void> reset() Reset an abundances object.

<void> serialize(<double(:)> historyArray←) Serialize an abundances object to an array.

<integer> serializeCount() Return a count of the number of properties in a serialized abundances object.

<void> setToUnity() Set an abundances object to unity.

<type(abundances)> subtract(<type(abundances)> abundances2→) Subtract one abundance from another.

accretionDisksADAF

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

<double> angularMomentum(<double> spinBlackHole→, <double> radius→) Return the dimensionless angular momentum of the ADAF at a given radius.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionDisksClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision efficiencyRadiative(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgrea
blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin)
Returns the radiative efficiency of the accretion disk.

<double> enthalpy(<double> spinBlackHole→, <double> radius→) Return the dimensionless enthalpy of the ADAF at a given radius.

<double> enthalpyAngularMomentumProduct(<double> spinBlackHole→, <double> radius→) Return the product of dimensionless enthalpy and angular momentum of the ADAF at a given radius.

<double> fieldEnhancement(<double> spinBlackHole→, <double> radius→) Return the magnetic field enhancement factor in the ADAF at the given radius.

<double> fluidAngularVelocity(<double> spinBlackHole→, <double> radius→) Return the dimensionless angular velocity of the ADAF fluid at the given radius.

<double> gamma(<double> spinBlackHole→, <double> radius→) Return the relativistic boost factor in the ADAF at a given radius.

<double> gammaAzimuthal(<double> spinBlackHole→, <double> radius→) Return the azimuthal part of the relativistic boost factor in the ADAF at a given radius.

<double> gammaRadial(<double> spinBlackHole→, <double> radius→) Return the radial part of the relativistic boost factor in the ADAF at a given radius.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<double> height(<double> spinBlackHole→, <double> radius→) Return the dimensionless height of the ADAF at a given radius.

<logical> isDefault() Return true if this is the default object of this class.

<double> jetPowerBlackHole(<double> spinBlackHole→, <double> radius→) Return the power of the jet launched by the black hole for the ADAF.

<double> jetPowerDisk(<double> spinBlackHole→, <double> radius→) Return the power of the jet launched from the disk for the ADAF.

<double> jetPowerDiskFromBlackHole(<double> spinBlackHole→, <double> radius→) Return the power of the jet launched from the disk which is derived frm the black hole.

type(varying_string) objectType() Return the type of the object.

double precision powerJet(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the power of the jet launched by the accretion disk in units of $M_\odot$ (km/s)^2 Gyr^{-1}.

double precision rateSpinUp(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the spin-up rate of the black hole due to accretion from the accretion disk.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> temperature(<double> spinBlackHole→, <double> radius→) Return the dimensionless temperature of the ADAF at a given radius.

<double> velocity(<double> spinBlackHole→, <double> radius→) Return the dimensionless velocity of the ADAF at a given radius.

<double> viscosityParameter(<double> spinBlackHole→) Return the viscosity parameter, α, in the ADAF.

accretionDisksClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision efficiencyRadiative(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgrea blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the radiative efficiency of the accretion disk.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision powerJet(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin)
Returns the power of the jet launched by the accretion disk in units of $M_\odot$ (km/s)^2 Gyr^{-1}.

double precision rateSpinUp(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin)
Returns the spin-up rate of the black hole due to accretion from the accretion disk.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionDisksEddingtonLimited

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionDisksClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision efficiencyRadiative(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgrea blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin)
Returns the radiative efficiency of the accretion disk.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision powerJet(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the power of the jet launched by the accretion disk in units of $M_\odot$ (km/s)^2 Gyr^{-1}.

double precision rateSpinUp(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the spin-up rate of the black hole due to accretion from the accretion disk.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionDiskSpectraClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionDiskSpectraClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision spectrum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} wavelength\argin) Returns the spectrum (in units of $L_\odot$ Hz^{-1}) of the accretion disk at the given wavelength (in units of Å) for node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionDiskSpectraFile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionDiskSpectraClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

void loadFile(<character(len=*)> fileName→) Load a file of AGN spectra.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision spectrum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textco double precision\textgreater} wavelength\argin) Returns the spectrum (in units of $L_\odot$ Hz^{-1}) of the accretion disk at the given wavelength (in units of Å) for node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionDiskSpectraHopkins2007

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> buildFile()` Build the tabulation file containing AGN spectra.

`void deepCopy(\textcolor{red}{\textless class((accretionDiskSpectraClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`void loadFile(<character(len=*)> fileName→)` Load a file of AGN spectra.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision spectrum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textco double precision\textgreater} wavelength\argin)` Returns the spectrum (in units of $L_\odot$ Hz^{-1}) of the accretion disk at the given wavelength (in units of Å) for `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

accretionDisksShakuraSunyaev

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((accretionDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision efficiencyRadiative(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgrea blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the radiative efficiency of the accretion disk.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision powerJet(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the power of the jet launched by the accretion disk in units of $M_\odot$ (km/s)^2 Gyr^{-1}.

double precision rateSpinUp(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the spin-up rate of the black hole due to accretion from the accretion disk.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionDisksSwitched

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision efficiencyRadiative(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgrea blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the radiative efficiency of the accretion disk.

<double> efficiencyRadiativeScalingADAF(<class(nodeComponentBlackHole)> blackHole→, <double> accretionRateMass→) Return the scaling of radiative efficiency of the ADAF component in a switched accretion disk.

<double> fractionADAF(<class(nodeComponentBlackHole)> blackHole→, <double> accretionRateMass→) Return the fraction of the accretion flow to be represented as an ADAF.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision powerJet(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the power of the jet launched by the accretion disk in units of $M_\odot$ (km/s)^2 Gyr^{-1}.

double precision rateSpinUp(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout,\textcolor{red}{\textless double precision\textgreater} accretionRateMass\argin) Returns the spin-up rate of the black hole due to accretion from the accretion disk.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionHaloBertschinger

double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te integer\textgreater} accretionMode\argin) Returns the mass (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

type(chemicalAbundances) accretedMassChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

type(abundances) accretedMassMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

`double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto `node` in the given `accretionMode`.

`type(chemicalAbundances) accretionRateChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto `node` in the given `accretionMode`.

`type(abundances) accretionRateMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto `node` in the given `accretionMode`.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`logical branchHasBaryons(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns `true` if this tree branch may accrete baryons, and `false` otherwise.

`void deepCopy(\textcolor{red}{\textless class((accretionHaloClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision failedAccretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision failedAccretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto `node` in the given `accretionMode`.

`double precision failedFraction(<type(treeNode)> *node↔)` Returns the fraction of potential accretion onto a halo from the IGM which fails.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityScale(<type(treeNode)> *node↔) Returns the velocity scale to use for node.

accretionHaloClass

double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te integer\textgreater} accretionMode\argin) Returns the mass (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

type(chemicalAbundances) accretedMassChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

type(abundances) accretedMassMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto node in the given accretionMode.

type(chemicalAbundances) accretionRateChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto node in the given accretionMode.

type(abundances) accretionRateMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto node in the given accretionMode.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

logical branchHasBaryons(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns true if this tree branch may accrete baryons, and false otherwise.

void deepCopy(\textcolor{red}{\textless class((accretionHaloClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision failedAccretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision failedAccretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto `node` in the given `accretionMode`.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

accretionHaloColdMode

`double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`type(chemicalAbundances) accretedMassChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`type(abundances) accretedMassMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto `node` in the given `accretionMode`.

type(chemicalAbundances) accretionRateChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto node in the given accretionMode.

type(abundances) accretionRateMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto node in the given accretionMode.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

logical branchHasBaryons(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns true if this tree branch may accrete baryons, and false otherwise.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

<type(chemicalAbundances)> chemicalMasses(<type(treeNode)> *node↔, <double>massAccreted→, <integer>accretionMode→) Returns the total accretion rate from the IGM onto a halo (including dark matter).

<double> coldModeFraction(<type(treeNode)> *node↔, <integer>accretionMode→) Returns the total accretion rate from the IGM onto a halo (including dark matter).

void deepCopy(\textcolor{red}{\textless class((accretionHaloClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision failedAccretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto node in the given accretionMode. Used to initialize nodes.

double precision failedAccretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto node in the given accretionMode.

double precision failedFraction(<type(treeNode)> *node↔) Returns the fraction of potential accretion onto a halo from the IGM which fails.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityScale(<type(treeNode)> *node↔) Returns the velocity scale to use for node.

accretionHaloNaozBarkana2007

double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te integer\textgreater} accretionMode\argin) Returns the mass (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

type(chemicalAbundances) accretedMassChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

type(abundances) accretedMassMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto node in the given accretionMode. Used to initialize nodes.

double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto node in the given accretionMode.

type(chemicalAbundances) accretionRateChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto node in the given accretionMode.

type(abundances) accretionRateMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin) Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto node in the given accretionMode.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

`logical branchHasBaryons(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns `true` if this tree branch may accrete baryons, and `false` otherwise.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

`void deepCopy(\textcolor{red}{\textless class((accretionHaloClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision failedAccretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision failedAccretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto `node` in the given `accretionMode`.

`double precision failedFraction(<type(treeNode)> *node↔)` Returns the fraction of potential accretion onto a halo from the IGM which fails.

`double precision filteredFraction(<type(treeNode)> *node↔)` Returns the fraction of potential accretion onto a halo from the IGM which succeeded.

`double precision filteredFractionCompute(<double> massHalo→, <double> massFiltering→)` Returns the fraction of potential accretion onto a halo from the IGM which succeeded given the halo and filtering masses.

`double precision filteredFractionRate(<type(treeNode)> *node↔)` Returns the fraction of potential accretion rate onto a halo from the IGM which succeeds.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision velocityScale(<type(treeNode)> *node↔)` Returns the velocity scale to use for `node`.

accretionHaloSimple

`double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`type(chemicalAbundances) accretedMassChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`type(abundances) accretedMassMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto `node` in the given `accretionMode`.

`type(chemicalAbundances) accretionRateChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto `node` in the given `accretionMode`.

`type(abundances) accretionRateMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto `node` in the given `accretionMode`.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`logical branchHasBaryons(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns `true` if this tree branch may accrete baryons, and `false` otherwise.

`void deepCopy(\textcolor{red}{\textless class((accretionHaloClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision failedAccretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision failedAccretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto `node` in the given `accretionMode`.

`double precision failedFraction(<type(treeNode)> *node↔)` Returns the fraction of potential accretion onto a halo from the IGM which fails.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl` `type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-` `size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles` `type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-` `size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision velocityScale(<type(treeNode)> *node↔)` Returns the velocity scale to use for `node`.

accretionHaloTotalBertschinger

`double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total accreted mass in the given `node`.

`double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater}` `node\arginout)` Return the total accretion rate onto the given `node`.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\` `character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((accretionHaloTotalClass))\textgreater} destination\argin` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex` `logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

accretionHaloTotalClass

double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the total accreted mass in the given node.

double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the total accretion rate onto the given node.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((accretionHaloTotalClass))\textgreater} destination\argin Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

accretionHaloTotalSimple

`double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total accreted mass in the given `node`.

`double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total accretion rate onto the given `node`.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((accretionHaloTotalClass))\textgreater} destination\argin` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

accretionHaloZero

`double precision accretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`type(chemicalAbundances) accretedMassChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`type(abundances) accretedMassMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision accretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto `node` in the given `accretionMode`.

`type(chemicalAbundances) accretionRateChemicals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto `node` in the given `accretionMode`.

`type(abundances) accretionRateMetals(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto `node` in the given `accretionMode`.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`logical branchHasBaryons(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns `true` if this tree branch may accrete baryons, and `false` otherwise.

`void deepCopy(\textcolor{red}{\textless class((accretionHaloClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision failedAccretedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes.

`double precision failedAccretionRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} accretionMode\argin)` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto `node` in the given `accretionMode`.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicCrossSectionIonizationPhotoClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision crossSection(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textco integer\textgreater} ionizationState\argin,\textcolor{red}{\textless integer\textgreater} shellNumber\argin,\textcolor{red}{\textless double precision\textgreater} wavelength\argin) Returns the cross-section for photoionization (in units of cm^2) for a given atom in a given ionization state at the specified wavelength (given in units of Å).

void deepCopy(\textcolor{red}{\textless class((atomicCrossSectionIonizationPhotoClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

atomicCrossSectionIonizationPhotoVerner

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision crossSection(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textco integer\textgreater} ionizationState\argin,\textcolor{red}{\textless integer\textgreater} shellNumber\argin,\textcolor{red}{\textless double precision\textgreater} wavelength\argin)` Returns the cross-section for photoionization (in units of cm^2) for a given atom in a given ionization state at the specified `wavelength` (given in units of Å).

`void deepCopy(\textcolor{red}{\textless class((atomicCrossSectionIonizationPhotoClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

atomicExcitationRateCollisionalClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

double precision coolingRate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcol integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin) Return the collisional excitation cooling rate , in units of J/m^3/s, for ion of given atomicNumber and electronNumber at temperature T (in Kelvin).

void deepCopy(\textcolor{red}{\textless class((atomicExcitationRateCollisionalClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicExcitationRateCollisionalScholzWalters1991

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision coolingRate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcol integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin) Return the collisional excitation cooling rate , in units of J/m^3/s, for ion of given atomicNumber and electronNumber at temperature T (in Kelvin).

void deepCopy(\textcolor{red}{\textless class((atomicExcitationRateCollisionalClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicIonizationPotentialClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((atomicIonizationPotentialClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolo integer\textgreater} electronNumber\argin) Returns the ionization potential (in units of eV) for a given atom in a given ionization state.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicIonizationPotentialVerner

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((atomicIonizationPotentialClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor
integer\textgreater} electronNumber\argin) Returns the ionization potential (in units of eV) for a given atom in a given ionization state.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicIonizationRateCollisionalClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((atomicIonizationRateCollisionalClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red}
integer\textgreater} ionizationState\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin) Returns the radiative recombination rate.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicIonizationRateCollisionalVerner1996

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((atomicIonizationRateCollisionalClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red}
integer\textgreater} ionizationState\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin) Returns the radiative recombination rate.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicRecombinationRateDielectronicArnaud1985

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((atomicRecombinationRateDielectronicClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red} integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin) Return the dielectroninc recombination rate (in units of cm^3 s^{-1}) for the ion of given atomicNumber and electronNumber at the given temperature (in Kelvin).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicRecombinationRateDielectronicClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((atomicRecombinationRateDielectronicClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red} integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin)` Return the dielectroninc recombination rate (in units of $\mathrm{cm}^3\ \mathrm{s}^{-1}$) for the ion of given `atomicNumber` and `electronNumber` at the given `temperature` (in Kelvin).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

atomicRecombinationRateRadiativeClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((atomicRecombinationRateRadiativeClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red}
integer\textgreater} ionizationState\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless integer\textgreater} level\argin) Returns
the radiative recombination rate.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the
new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

atomicRecombinationRateRadiativeVerner1996

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names al-
lowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((atomicRecombinationRateRadiativeClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which
could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red}
integer\textgreater} ionizationState\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless integer\textgreater} level\argin) Returns
the radiative recombination rate.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the
new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

blackHoleBinaryInitialSeparationClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryInitialSeparationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision separationInitial(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} nodeHost\arginout) Computes the initial separation of a newly formed black hole binary black holes.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

blackHoleBinaryInitialSeparationSpheroidRadiusFraction

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryInitialSeparationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision separationInitial(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} nodeHost\arginout)` Computes the initial separation of a newly formed black hole binary black holes.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

blackHoleBinaryInitialSeparationTidalRadius

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryInitialSeparationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision separationInitial(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} nodeHost\arginout) Computes the initial separation of a newly formed black hole binary black holes.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

blackHoleBinaryInitialSeparationVolonteri2003

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryInitialSeparationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision separationInitial(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} nodeHost\arginout) Computes the initial separation of a newly formed black hole binary black holes.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

blackHoleBinaryMergerClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryMergerClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

void merge(\textcolor{red}{\textless double precision\textgreater} blackHoleMassA\argin,\textcolor{red} double precision\textgreater} blackHoleMassB\argin,\textcolor{red}{\textless double precision\textgreater} blackHoleSpinA\argin,\textcolor{red}{\textless double precision\textgreater} blackHoleSpinB\argin,\textcolor{red}{\textless double precision\textgreater} blackHoleMassFinal\arg double precision\textgreater} blackHoleSpinFinal\argout) The the properties of the black hole resulting from a binary merger.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

blackHoleBinaryMergerRezzolla2008

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryMergerClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`void merge(\textcolor{red}{\textless double precision\textgreater} blackHoleMassA\argin,\textcolor{red} double precision\textgreater} blackHoleMassB\argin,\textcolor{red}{\textless double precision\textgreater} blackHoleSpinA\argin,\textcolor{red}{\textless double precision\textgreater} blackHoleSpinB\argin,\textcolor{red}{\textless double precision\textgreater} blackHoleMassFinal\arg double precision\textgreater} blackHoleSpinFinal\argout)` The the properties of the black hole resulting from a binary merger.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

blackHoleBinaryRecoilCampanelli2007

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryRecoilClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision velocity(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole1\arginout,\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole2\arginout)` Computes the recoil velocity of the given pair of merging black holes.

blackHoleBinaryRecoilClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryRecoilClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocity(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole1\arginout,\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole2\arginout) Computes the recoil velocity of the given pair of merging black holes.

blackHoleBinaryRecoilZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((blackHoleBinaryRecoilClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocity(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole1\arginout,\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole2\arginout) Computes the recoil velocity of the given pair of merging black holes.

blackHoleBinarySeparationGrowthRateClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinarySeparationGrowthRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision growthRate(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout)` Computes the rate of growth of the separation of the given black hole and its binary companion in units of Mpc/Gyr.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

blackHoleBinarySeparationGrowthRateStandard

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((blackHoleBinarySeparationGrowthRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

double precision growthRate(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout) Computes the rate of growth of the separation of the given black hole and its binary companion in units of Mpc/Gyr.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

blackHoleBinarySeparationGrowthRateZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((blackHoleBinarySeparationGrowthRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision growthRate(\textcolor{red}{\textless class((nodeComponentBlackHole))\textgreater} blackHole\arginout) Computes the rate of growth of the separation of the given black hole and its binary companion in units of Mpc/Gyr.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

cap

<logical> pointIncluded(<double(3)> point→) Return true if the given point lives inside the MANGLE cap.

chemicalAbundances

<double> abundance(<integer> moleculeIndex→) Returns the abundance of a chemical given its index.

<void> abundanceSet(<integer> moleculeIndex→, <double> abundance→) Sets the abundance of a chemical given its index.

<type(chemicalAbundances)> add(<type(chemicalAbundances)> abundances2→) Add two chemical abundances.

<void> builder(<*type(node)> chemicalAbundancesDefinition→) Build a chemical abundances object from an XML definition.

<void> deserialize(<double(:)> chemicalAbundancesArray→) Deserialize a chemical abundances object from an array.

<void> destroy() Destroys a chemical abundances object.

<type(chemicalAbundances)> divide(<double> divisor→) Divide a chemical abundance by a scalar.

<void> dump() Dump a chemical abundances object.

<void> dumpRaw(<integer> fileHandle→) Dump a chemical abundances object in binary.

<void> enforcePositive() Enforces all chemical values to be positive.

<void> increment(<type(chemicalAbundances)> addAbundances→) Increment a chemical abundances object.

<logical> isZero() Return true if a chemicals object is zero.

<void> massToNumber(<type(chemicalAbundances)> chemicalsByNumber↔) Converts from abundances by mass to abundances by number.

<type(chemicalAbundances)> multiply(<double> multiplier→) Multiply a chemical abundance by a scalar.

<integer(c_size_t) > nonStaticSizeOf() Returns the size of any non-static components of the type.

<void> numberToMass(<type(chemicalAbundances)> chemicalsByMass↔) Converts from abundances by number to abundances by mass.

<void> readRaw(<integer> fileHandle→) Read a chemical abundances object in binary.

<void> reset() Resets abundances to zero.

<void> serialize(<double(:)> chemicalAbundancesArray←) Serialize a chemical abundances object to an array.

<integer> serializeCount() Return a count of the number of properties in a serialized chemical abundances object.

<void> setToUnity() Set abundances to unity.

<type(chemicalAbundances)> subtract(<type(chemicalAbundances)> abundances2→) Subtract one chemical abundance from another.

chemicalReactionRateClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((chemicalReactionRateClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void rates(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\t
type((chemicalAbundances))\textgreater} chemicalDensity\argin,\textcolor{red}{\textless
class((radiationFieldClass))\textgreater} radiation\arginout,\textcolor{red}{\textless
type((chemicalAbundances))\textgreater} chemicalRates\arginout,\textcolor{red}{\textless
type((treeNode))\textgreater} node\arginout) Return the collisional excitation cooling rate , in units of $\mathrm{J/m^3/s}$, for ion of given atomicNumber and electronNumber at temperature T (in Kelvin).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

chemicalReactionRateHydrogenNetwork

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((chemicalReactionRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<void> rateH2_Electron_to_2H_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2 + \mathrm{e}^- \rightarrow 2\mathrm{H} + \mathrm{e}^-$.

`<void> rateH2_Gamma_to_2H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \gamma \rightarrow 2\mathrm{H}^+ + \mathrm{e}^-$.

`<void> rateH2_Gamma_to_H2plus_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2 + \gamma \rightarrow \mathrm{H}_2^+ + \mathrm{e}^-$.

`<void> rateH2_Gamma_to_H2star_to_2H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \gamma \rightarrow 2\mathrm{H}^+ + \mathrm{e}^-$.

`<void> rateH2_H_to_3H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2 + \mathrm{H} \rightarrow 3\mathrm{H}$.

`<void> rateH2_Hplus_to_H2plus_H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2 + \mathrm{H}^+ \rightarrow \mathrm{H}_2^+ + \mathrm{H}$.

`<void> rateH2plus_Electron_to_2H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \mathrm{e}^- \rightarrow 2\mathrm{H}$.

`<void> rateH2plus_Gamma_to_2Hplus_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \gamma \rightarrow 2\mathrm{H}^+ + \mathrm{e}^-$.

`<void> rateH2plus_Gamma_to_H_Hplus(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \gamma \rightarrow \mathrm{H} + \mathrm{H}^+$.

`<void> rateH2plus_H_to_H2_Hplus(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \mathrm{H} \rightarrow \mathrm{H}_2 + \mathrm{H}^+$.

`<void> rateH2plus_Hminus_to_H2_H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \mathrm{H}^- \rightarrow \mathrm{H}_2 + \mathrm{H}$.

`<void> rateH_Electron_to_Hminus_Photon(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H} + \mathrm{e}^- \rightarrow \mathrm{H}^- + \gamma$.

`<void> rateH_Electron_to_Hplus_2Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H} + \mathrm{e}^- \rightarrow \mathrm{H}^+ + 2\mathrm{e}^-$.

`<void> rateH_Gamma_to_Hplus_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H} + \gamma \rightarrow \mathrm{H}^+ + \mathrm{e}^-$.

`<void> rateH_Hminus_to_H2_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H} + \mathrm{H}^- \rightarrow \mathrm{H}_2 + \mathrm{e}^-$.

`<void> rateH_Hplus_to_H2plus_Photon(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H} + \mathrm{H}^+ \rightarrow \mathrm{H}_2^+ + \gamma$.

`<void> rateHminus_Electron_to_H_2Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{cm}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}_2^+ + \mathrm{H} \rightarrow \mathrm{H}_2 + \mathrm{H}^+$.

`<void> rateHminus_Gamma_to_H_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔, <type(treeNode)> node↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}^- + \gamma \rightarrow \mathrm{H} + \mathrm{e}^-$.

`<void> rateHminus_H_to_2H_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔)` Computes the rate (in units of $\mathrm{c}^{-3}\ \mathrm{s}^{-1}$) for the reaction $\mathrm{H}^- + \mathrm{H} \rightarrow 2\mathrm{H} + \mathrm{e}^-$.

<void> rateHminus_Hplus_to_2H(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔) Computes the rate (in units of c^{-3} s^{-1}) for the reaction $H_2^+ + H \rightarrow H_2 + H^+$.

<void> rateHminus_Hplus_to_H2plus_Electron(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔) Computes the rate (in units of cm^{-3} s^{-1}) for the reaction $H^- + H^+ \rightarrow H_2^+ + e^-$.

<void> rateHplus_Electron_to_H_Photon(<double> temperature→, <class(radiationFieldClass) radiation>↔, <type(chemicalAbundances) chemicalDensity>→, <type(chemicalAbundances)> chemicalRates↔) Computes the rate (in units of c^{-3} s^{-1}) for the reaction $H^+ + e^- \rightarrow H + \gamma$.

void rates(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\t type((chemicalAbundances))\textgreater} chemicalDensity\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalRates\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the collisional excitation cooling rate , in units of $J/m^3/s$, for ion of given atomicNumber and electronNumber at temperature T (in Kelvin).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

chemicalReactionRateZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((chemicalReactionRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void rates(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\t
type((chemicalAbundances))\textgreater} chemicalDensity\argin,\textcolor{red}{\textless
class((radiationFieldClass))\textgreater} radiation\arginout,\textcolor{red}{\textless
type((chemicalAbundances))\textgreater} chemicalRates\arginout,\textcolor{red}{\textless
type((treeNode))\textgreater} node\arginout) Return the collisional excitation cooling rate , in units of J/m^3/s, for ion of given atomicNumber and electronNumber at temperature T (in Kelvin).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

chemicalStateAtomicCIECloudy

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void chemicalDensities(\textcolor{red}{\textless type((chemicalAbundances))\textgreater}
chemicalDensities\arginout,\textcolor{red}{\textless double precision\textgreater}
numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t
class((radiationFieldClass))\textgreater} radiation\arginout) Return the densities of chemical species at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm$^-$3.

void deepCopy(\textcolor{red}{\textless class((chemicalStateClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision electronDensity(\textcolor{red}{\textless double precision\textgreater}
numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t
class((radiationFieldClass))\textgreater} radiation\arginout) Return the electron density at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm$^-$3.

double precision electronDensityDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout) Return the logarithmic gradient of electron density with respect to density at the given temperature and hydrogen density for the specified set of abundances and radiation field.

double precision electronDensityTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout) Return the logarithmic gradient of electron density with temperature at the given temperature and hydrogen density for the specified set of abundances and radiation field.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<double> interpolate(<integer(c_size_t)> iTemperature→, <double> hTemperature→, <integer(c_size_t)> iMetallicity→, <double> hMetallicity→, <double(:,:)> density→) Interpolate in the given density table.

void interpolatingFactors(<double> temperature→, <double> metallicity→, <integer(c_size_t)> iTemperature←, <double> hTemperature←, <integer(c_size_t)> iMetallicity←, <double> hMetallicity←) Compute interpolating factors in a CIE chemical state file.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void readFile(<char(len=*)> fileName→) Read the named chemical state file.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void tabulate(<type(abundances)> gasAbunances→) Run Cloudy to tabulate chemical state as necessary.

chemicalStateCIEFile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void chemicalDensities(\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities\arginout,\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout)` Return the densities of chemical species at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm^{-}3.

`void deepCopy(\textcolor{red}{\textless class((chemicalStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision electronDensity(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout)` Return the electron density at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm^{-}3.

`double precision electronDensityDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout)` Return the logarithmic gradient of electron density with respect to density at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`double precision electronDensityTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout)` Return the logarithmic gradient of electron density with temperature at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<double> interpolate(<integer(c_size_t)> iTemperature→, <double> hTemperature→, <integer(c_size_t)> iMetallicity→, <double> hMetallicity→, <double(:,:)> density→)` Interpolate in the given density table.

`void interpolatingFactors(<double> temperature→, <double> metallicity→, <integer(c_size_t)> iTemperature←, <double> hTemperature←, <integer(c_size_t)> iMetallicity←, <double> hMetallicity←)` Compute interpolating factors in a CIE chemical state file.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void readFile(<char(len=*)> fileName→)` Read the named chemical state file.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

chemicalStateClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void chemicalDensities(\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities\arginout,\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout) Return the densities of chemical species at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm^{-}3.

void deepCopy(\textcolor{red}{\textless class((chemicalStateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision electronDensity(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout) Return the electron density at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm^{-}3.

double precision electronDensityDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout) Return the logarithmic gradient of electron density with respect to density at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`double precision electronDensityTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t class((radiationFieldClass))\textgreater} radiation\arginout)` Return the logarithmic gradient of electron density with temperature at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

chemicalStructure

`<integer> charge()` Return the charge of a chemical.

`<void> export(<character(len=*)> coutputFile→)` Write a chemical structure to a CML file.

`<double> mass()` Return the mass of a chemical in atomic mass units.

`<void> retrieve(<character(len=*)> chemicalName→)` Get a chemical from the database.

coldModeInfallRateClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coldModeInfallRateClass))\textgreater} destination\argin` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision infallRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the cold mode infall rate for `thisNode` (in units of $M_\odot$ Gyr^{-1}).

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coldModeInfallRateDynamicalTime

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coldModeInfallRateClass))\textgreater} destination\argir` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision infallRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the cold mode infall rate for `thisNode` (in units of $M_\odot$ Gyr^{-1}).

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

conditionalMassFunctionBehroozi2010

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> compute(<double> massHalo→, <double> mass→, <double> numberCentrals←, <double> numberSatellites←)` Compute the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$.

`void deepCopy(\textcolor{red}{\textless class((conditionalMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massFunction(\textcolor{red}{\textless double precision\textgreater} massHalo\argin,\t double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} galaxyType\argin)` Return the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$.

`double precision massFunctionVariance(\textcolor{red}{\textless double precision\textgreater} massHalo\argin,\textcolor{red}{\textless double precision\textgreater} massLow\argin,\textcolor{red double precision\textgreater} massHigh\argin)` Return the variance in the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

conditionalMassFunctionClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((conditionalMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massFunction(\textcolor{red}{\textless double precision\textgreater} massHalo\argin,\t double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} galaxyType\argin)` Return the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$.

`double precision massFunctionVariance(\textcolor{red}{\textless double precision\textgreater} massHalo\argin,\textcolor{red}{\textless double precision\textgreater} massLow\argin,\textcolor{red double precision\textgreater} massHigh\argin)` Return the variance in the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingFunctionAtomicCIECloudy

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

double precision coolingFunction(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs cm$^-$3 s^{-1}.

double precision coolingFunctionDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

double precision coolingFunctionTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

void deepCopy(\textcolor{red}{\textless class((coolingFunctionClass))\textgreater} destination\arginout Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<double> interpolate(<integer(c_size_t)> iTemperature→, <double> hTemperature→, <integer(c_size_t)> iMetallicity→, <double> hMetallicity→) Interpolate in the cooling function.

void interpolatingFactors(<double> temperature→, <double> metallicity→, <integer(c_size_t)> iTemperature←, <double> hTemperature←, <integer(c_size_t)> iMetallicity←, <double> hMetallicity←) Compute interpolating factors in a CIE cooling function file.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void readFile(<char(len=*)> fileName→) Read the named cooling function file.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(<type(abundances)> gasAbunances→)` Run CLOUDY to tabulate the cooling function as necessary.

coolingFunctionCIEFile

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision coolingFunction(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs $\mathrm{cm}^{-}3\ \mathrm{s}^{-1}$.

`double precision coolingFunctionDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`double precision coolingFunctionTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`void deepCopy(\textcolor{red}{\textless class((coolingFunctionClass))\textgreater} destination\arginout` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<double> interpolate(<integer(c_size_t)> iTemperature→, <double> hTemperature→, <integer(c_size_t)> iMetallicity→, <double> hMetallicity→) Interpolate in the cooling function.

void interpolatingFactors(<double> temperature→, <double> metallicity→, <integer(c_size_t)> iTemperature←, <double> hTemperature←, <integer(c_size_t)> iMetallicity←, <double> hMetallicity←) Compute interpolating factors in a CIE cooling function file.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void readFile(<char(len=*)> fileName→) Read the named cooling function file.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingFunctionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision coolingFunction(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs cm^{-}3 s^{-1}.

double precision coolingFunctionDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`double precision coolingFunctionTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`void deepCopy(\textcolor{red}{\textless class((coolingFunctionClass))\textgreater} destination\arginout` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingFunctionCMBCompton

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision coolingFunction(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs $\mathrm{cm}^{-}3\ \mathrm{s}^{-1}$.

`double precision coolingFunctionDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`double precision coolingFunctionTemperatureLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout)` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

`void deepCopy(\textcolor{red}{\textless class((coolingFunctionClass))\textgreater} destination\arginout` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingFunctionMolecularHydrogenGalliPalla

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

void commonFactors(<double> numberDensityHydrogen→, <double> temperature→, <double> numberDensityCrit
<double> coolingFunctionLocalThermodynamicEquilibrium←, <double> coolingFunctionLowDensityLimit←)
Compute common factors.

double precision coolingFunction(\textcolor{red}{\textless double precision\textgreater}
numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t
type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless
class((radiationFieldClass))\textgreater} radiation\arginout) Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs cm^{-}3 s^{-1}.

double precision coolingFunctionDensityLogSlope(\textcolor{red}{\textless double precision\textgreater}
numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t
type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless
class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

<double> coolingFunctionH2Plus_Electron(<double> temperature→,<type(chemicalAbundances)>
chemicalDensities→) Compute the cooling function due to H_2^+–e^-.

<double> coolingFunctionH_H2(<double> numberDensityHydrogen→, <double> temperature→,<type(chemicalAbu
chemicalDensities→) Compute the cooling function due to H–H_2.

<double> coolingFunctionH_H2Plus(<double> temperature→,<type(chemicalAbundances)> chemicalDensities→)
Compute the cooling function due to H–H_2^+.

double precision coolingFunctionTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea
numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater}
temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t
type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless
class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

void deepCopy(\textcolor{red}{\textless class((coolingFunctionClass))\textgreater} destination\arginout
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingFunctionSummation

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision coolingFunction(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs cm^{-}3 s^{-1}.

double precision coolingFunctionDensityLogSlope(\textcolor{red}{\textless double precision\textgreater} numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

double precision coolingFunctionTemperatureLogSlope(\textcolor{red}{\textless double precision\textgrea numberDensityHydrogen\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances\argin,\t type((chemicalAbundances))\textgreater} chemicalDensities\argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation\arginout) Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field.

void deepCopy(\textcolor{red}{\textless class((coolingFunctionClass))\textgreater} destination\arginout Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingInfallRadiusClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingInfallRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the infall radius for node (in units of Mpc).

double precision radiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate at which the infall radius grows for node (in units of Mpc/Gyr).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingInfallRadiusCoolingFreefall

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingInfallRadiusClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the infall radius for `node` (in units of Mpc).

`double precision radiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate at which the infall radius grows for `node` (in units of Mpc/Gyr).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingInfallRadiusCoolingRadius

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingInfallRadiusClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the infall radius for `node` (in units of Mpc).

`double precision radiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate at which the infall radius grows for `node` (in units of Mpc/Gyr).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingRadiusBetaProfile

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

`void deepCopy(\textcolor{red}{\textless class((coolingRadiusClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc.

double precision radiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of increase of the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRadiusClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc.

double precision radiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of increase of the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRadiusIsothermal

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((coolingRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc.

double precision radiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of increase of the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRadiusSimple

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((coolingRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc.

double precision radiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of increase of the cooling radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in `node` in units of $M_\odot$/Gyr.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingRateCole2000

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateCutOff

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateMultiplier

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateNoCoolingSatellites

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateSimple

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateSimpleScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateVelocityMaximumScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingRateWhiteFrenk1991

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in `node` in units of $M_\odot$/Gyr.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingRateZero

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingSpecificAngularMomentumClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularMomentumSpecific(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)
Return the specific angular momentum (in units of km/s Mpc) of cooling gas in node.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingSpecificAngularMomentumClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingSpecificAngularMomentumConstantRotation

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularMomentumSpecific(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the specific angular momentum (in units of km/s Mpc) of cooling gas in node.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((coolingSpecificAngularMomentumClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

coolingSpecificAngularMomentumMean

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularMomentumSpecific(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the specific angular momentum (in units of km/s Mpc) of cooling gas in `node`.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingSpecificAngularMomentumClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

coolingTimeAvailableClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((coolingTimeAvailableClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeAvailable(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Return the time available for cooling in node in units of Gyr.

double precision timeAvailableIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Return the rate at which the time available for cooling increases in node (dimensionless).

coolingTimeAvailableFormationTime

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingTimeAvailableClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeAvailable(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the time available for cooling in node in units of Gyr.

double precision timeAvailableIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate at which the time available for cooling increases in node (dimensionless).

coolingTimeAvailableWhiteFrenk1991

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingTimeAvailableClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeAvailable(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the time available for cooling in node in units of Gyr.

double precision timeAvailableIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate at which the time available for cooling increases in node (dimensionless).

coolingTimeClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingTimeClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientDensityLogarithmic(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} density\argin,\textcolor{ type((abundances))\textgreater} gasAbundances \argin,\textcolor{red}{\textless type((chemicalAbund))\textgreater} chemicalDensities \argin,\textcolor{red}{\textless class((radiationFieldClass))\tex radiation \arginout) Returns the logarithmic derivative of cooling time with respect to density for gas in the hot atmosphere surrounding the galaxy.

double precision gradientTemperatureLogarithmic(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} density\argin,\textcolor{ type((abundances))\textgreater} gasAbundances \argin,\textcolor{red}{\textless type((chemicalAbund))\textgreater} chemicalDensities \argin,\textcolor{red}{\textless class((radiationFieldClass))\tex radiation \arginout) Returns the logarithmic derivative of cooling time with respect to temperature for gas in the hot atmosphere surrounding the galaxy.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision time(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} density\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances \argin,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities \argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation \arginout) Returns the cooling time for gas in the hot atmosphere surrounding the galaxy in units of Gyr.

coolingTimeSimple

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\textcolor{red}{\textless character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((coolingTimeClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientDensityLogarithmic(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} density\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances \argin,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities \argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation \arginout) Returns the logarithmic derivative of cooling time with respect to density for gas in the hot atmosphere surrounding the galaxy.

double precision gradientTemperatureLogarithmic(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} density\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances \argin,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities \argin,\textcolor{red}{\textless class((radiationFieldClass))\textgreater} radiation \arginout) Returns the logarithmic derivative of cooling time with respect to temperature for gas in the hot atmosphere surrounding the galaxy.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision time(\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcc double precision\textgreater} density\argin,\textcolor{red}{\textless type((abundances))\textgreater} gasAbundances \argin,\textcolor{red}{\textless type((chemicalAbundances))\textgreater} chemicalDensities \argin,\textcolor{red}{\textless class((radiationFieldClass))\tex radiation \arginout) Returns the cooling time for gas in the hot atmosphere surrounding the galaxy in units of Gyr.

coordinate

<void> fromCartesian(<double(3)> x→) Set the coordinates from a Cartesian system specified as a 3-element array.

<double> rCylindrical() Return the cylindrical radial coordinate.

<double(3)> toCartesian() Return the coordinates in a Cartesian system as a 3-element array.

coordinateCartesian

<void> fromCartesian(<double(3)> x→) Set the coordinates from a Cartesian system specified as a 3-element array.

<double> rCylindrical() Return the cylindrical radial coordinate.

<double(3)> toCartesian() Return the coordinates in a Cartesian system as a 3-element array.

<double> x() Get the x-coordinate.

<void> xSet(<double> x→) set the x-coordinate.

<double> y() Get the y-coordinate.

<void> ySet(<double> y→) set the y-coordinate.

<double> z() Get the z-coordinate.

<void> zSet(<double> z→) set the z-coordinate.

coordinateCylindrical

<void> fromCartesian(<double(3)> x→) Set the coordinates from a Cartesian system specified as a 3-element array.

<double> phi() Get the ϕ-coordinate.

<void> phiSet(<double> phi→) set the ϕ-coordinate.

<double> r() Get the r-coordinate.

<double> rCylindrical() Return the cylindrical radial coordinate.

<void> rSet(<double> r→) set the r-coordinate.

<double(3)> toCartesian() Return the coordinates in a Cartesian system as a 3-element array.

<double> z() Get the z-coordinate.

<void> zSet(<double> z→) set the z-coordinate.

coordinateSpherical

<void> fromCartesian(<double(3)> x→) Set the coordinates from a Cartesian system specified as a 3-element array.

<double> phi() Get the ϕ-coordinate.

<void> phiSet(<double> phi→) set the ϕ-coordinate.

<double> r() Get the r-coordinate.

<double> rCylindrical() Return the cylindrical radial coordinate.

<void> rSet(<double> r→) set the r-coordinate.

<double> theta() Get the θ-coordinate.

<void> thetaSet(<double> theta→) set the θ-coordinate.

<double(3)> toCartesian() Return the coordinates in a Cartesian system as a 3-element array.

cosmologicalMassVarianceClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((cosmologicalMassVarianceClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision mass(\textcolor{red}{\textless double precision\textgreater} rootVariance\argin)
Return the mass corresponding to the given rootVariance of the cosmological density field.

type(varying_string) objectType() Return the type of the object.

double precision powerNormalization() Return the normalization of the power spectrum.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rootVariance(\textcolor{red}{\textless double precision\textgreater} mass\argin) Return the root-variance of the cosmological density field.

void rootVarianceAndLogarithmicGradient(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} rootVariance\argout,\textcolor{r double precision\textgreater} rootVarianceLogarithmicGradient\argout) Return the value and logarithmic gradient with respect to mass of the root-variance of the cosmological density field.

double precision rootVarianceLogarithmicGradient(\textcolor{red}{\textless double precision\textgreate mass\argin) Return the logarithmic gradient of the root-variance of the cosmological density field with respect to mass.

double precision sigma8() Return the value of σ_8.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

cosmologicalMassVarianceFilteredPower

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((cosmologicalMassVarianceClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision mass(\textcolor{red}{\textless double precision\textgreater} rootVariance\argin) Return the mass corresponding to the given rootVariance of the cosmological density field.

type(varying_string) objectType() Return the type of the object.

double precision powerNormalization() Return the normalization of the power spectrum.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void retabulate(<double> time→) Tabulate cosmological mass variance.

double precision rootVariance(\textcolor{red}{\textless double precision\textgreater} mass\argin) Return the root-variance of the cosmological density field.

void rootVarianceAndLogarithmicGradient(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} rootVariance\argout,\textcolor{r double precision\textgreater} rootVarianceLogarithmicGradient\argout) Return the value and logarithmic gradient with respect to mass of the root-variance of the cosmological density field.

double precision rootVarianceLogarithmicGradient(\textcolor{red}{\textless double precision\textgreate mass\argin) Return the logarithmic gradient of the root-variance of the cosmological density field with respect to mass.

double precision sigma8() Return the value of σ_8.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

cosmologicalMassVariancePeakBackgroundSplit

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((cosmologicalMassVarianceClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision mass(\textcolor{red}{\textless double precision\textgreater} rootVariance\argin) Return the mass corresponding to the given rootVariance of the cosmological density field.

type(varying_string) objectType() Return the type of the object.

double precision powerNormalization() Return the normalization of the power spectrum.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rootVariance(\textcolor{red}{\textless double precision\textgreater} mass\argin)` Return the root-variance of the cosmological density field.

`void rootVarianceAndLogarithmicGradient(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} rootVariance\argout,\textcolor{r double precision\textgreater} rootVarianceLogarithmicGradient\argout)` Return the value and logarithmic gradient with respect to mass of the root-variance of the cosmological density field.

`double precision rootVarianceLogarithmicGradient(\textcolor{red}{\textless double precision\textgreate mass\argin)` Return the logarithmic gradient of the root-variance of the cosmological density field with respect to mass.

`double precision sigma8()` Return the value of σ_8.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

cosmologyFunctionsClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision comovingVolumeElementRedshift(\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}z = r_\mathrm{c}^2(t)\mathrm{c}H^{-1}(t)$ (where r_c is the comoving distance to time t and $H(t)$ is the Hubble parameter at that time) for unit solid angle at the specified `time`.

`double precision comovingVolumeElementTime(\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}t = r_\mathrm{c}^2(t)\mathrm{c}a(t)$ (where r_c is the comoving distance to time t and $a(t)$ is the expansion at that time) for unit solid angle at the specified `time`.

`double precision cosmicTime(\textcolor{red}{\textless double precision\textgreater} expansionFactor\arg logical\textgreater} collapsingPhase\argin)` Return the cosmological age at the given expansion factor.

`void deepCopy(\textcolor{red}{\textless class((cosmologyFunctionsClass))\textgreater} destination\argin` Perform a deep copy of the object.

`void densityScalingEarlyTime(\textcolor{red}{\textless double precision\textgreater} dominateFactor\arg double precision\textgreater} densityPower\argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorDominant\argout,\textcolor{red}{\textless double precision\textgreater} OmegaDominant\argout)` Compute the scaling of density with expansion factor at early times in the universe.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceAngular(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the angular diameter distance to the given cosmic `time`.

`double precision distanceComoving(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the comoving distance to the given cosmic `time`.

`double precision distanceComovingConvert(\textcolor{red}{\textless integer\textgreater} output\argin,\textcolor{red}{\textless double precision\textgreater} distanceLuminosity\argin,\text double precision\textgreater} distanceModulus\argin,\textcolor{red}{\textless double precision\textgreater} distanceModulusKCorrected\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin)` Convert between different measures of comoving distance.

`double precision distanceLuminosity(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the luminosity distance to the given cosmic `time`.

`double precision dominationEpochMatter(\textcolor{red}{\textless double precision\textgreater} dominateFactor\argin)` Compute the epoch at which matter dominates over other forms of energy by a given factor.

`double precision epochTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolo double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsingPhase\argin)` Convenience function that returns the time corresponding to an epoch specified by time or expansion factor.

`void epochValidate(\textcolor{red}{\textless double precision\textgreater} timeIn \argin,\textcolor{red double precision\textgreater} expansionFactorIn \argin,\textcolor{red}{\textless logical\textgreate collapsingIn \argin,\textcolor{red}{\textless double precision\textgreater} timeOut \argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorOut\argout,\textcolo logical\textgreater} collapsingOut \argout)` Check the given cosmic epoch is valid (aborting otherwise) and, optionally, return time or expansion factor associated with the epoch.

`double precision equalityEpochMatterCurvature(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-curvature magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterDarkEnergy(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-dark energy magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterRadiation(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-radiation magnitude equality (either expansion factor or cosmic time).

`double precision equationOfStateDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` HASH(0x1fe6c28)

`double precision expansionFactor(\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the expansion factor at cosmological time `time`.

double precision expansionFactorFromRedshift(\textcolor{red}{\textless double precision\textgreater} redshift\argin) Returns expansion factor given a redshift.

double precision expansionRate(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin) Returns the cosmological expansion rate, $\dot{a}/a$ at expansion factor expansionFactor.

double precision exponentDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin) HASH(0x1fea6a0)

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision hubbleParameterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Returns the Hubble parameter at the requested cosmological time, time, or expansion factor, expansionFactor.

double precision hubbleParameterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Returns the rate of change of the Hubble parameter at the requested cosmological time, time, or expansion factor, expansionFactor.

<logical> isDefault() Return true if this is the default object of this class.

double precision matterDensityEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Convenience function that returns the matter density at the specified epoch.

type(varying_string) objectType() Return the type of the object.

double precision omegaDarkEnergyEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the dark energy density parameter at expansion factor expansionFactor.

double precision omegaMatterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the matter density parameter at expansion factor expansionFactor.

double precision omegaMatterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the rate of change of the matter density parameter at expansion factor expansionFactor.

double precision redshiftFromExpansionFactor(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin) Returns redshift for a given expansion factor.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperatureCMBEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the temperature of the cosmic microwave background at expansionFactor.

double precision timeAtDistanceComoving(\textcolor{red}{\textless double precision\textgreater} comovingDistance\argin) Return the cosmic time corresponding to the given comovingDistance.

double precision timeBigCrunch() Return the cosmological age at Big Crunch (or a negative value if no Big Crunch occurs).

cosmologyFunctionsMatterDarkEnergy

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision comovingVolumeElementRedshift(\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}z = r_\mathrm{c}^2(t)\mathrm{c}H^{-1}(t)$ (where r_c is the comoving distance to time t and $H(t)$ is the Hubble parameter at that time) for unit solid angle at the specified time.

double precision comovingVolumeElementTime(\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}t = r_\mathrm{c}^2(t)\mathrm{c}a(t)$ (where r_c is the comoving distance to time t and $a(t)$ is the expansion at that time) for unit solid angle at the specified time.

double precision cosmicTime(\textcolor{red}{\textless double precision\textgreater} expansionFactor\arg logical\textgreater} collapsingPhase\argin) Return the cosmological age at the given expansion factor.

void deepCopy(\textcolor{red}{\textless class((cosmologyFunctionsClass))\textgreater} destination\argin Perform a deep copy of the object.

void densityScalingEarlyTime(\textcolor{red}{\textless double precision\textgreater} dominateFactor\arg double precision\textgreater} densityPower\argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorDominant\argout,\textcolor{red}{\textless double precision\textgreater} OmegaDominant\argout) Compute the scaling of density with expansion factor at early times in the universe.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceAngular(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the angular diameter distance to the given cosmic `time`.

`double precision distanceComoving(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the comoving distance to the given cosmic `time`.

`double precision distanceComovingConvert(\textcolor{red}{\textless integer\textgreater} output\argin,\textcolor{red}{\textless double precision\textgreater} distanceLuminosity\argin,\text double precision\textgreater} distanceModulus\argin,\textcolor{red}{\textless double precision\textgreater} distanceModulusKCorrected\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin)` Convert between different measures of comoving distance.

`double precision distanceLuminosity(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the luminosity distance to the given cosmic `time`.

`void distanceTabulate(<double> time→)` Tabulate comoving distance as a function of cosmic time.

`double precision dominationEpochMatter(\textcolor{red}{\textless double precision\textgreater} dominateFactor\argin)` Compute the epoch at which matter dominates over other forms of energy by a given factor.

`double precision epochTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolo double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsingPhase\argin)` Convenience function that returns the time corresponding to an epoch specified by time or expansion factor.

`void epochValidate(\textcolor{red}{\textless double precision\textgreater} timeIn \argin,\textcolor{red double precision\textgreater} expansionFactorIn \argin,\textcolor{red}{\textless logical\textgreate collapsingIn \argin,\textcolor{red}{\textless double precision\textgreater} timeOut \argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorOut\argout,\textcolo logical\textgreater} collapsingOut \argout)` Check the given cosmic epoch is valid (aborting otherwise) and, optionally, return time or expansion factor associated with the epoch.

`double precision equalityEpochMatterCurvature(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-curvature magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterDarkEnergy(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-dark energy magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterRadiation(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-radiation magnitude equality (either expansion factor or cosmic time).

`double precision equationOfStateDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` HASH(0x1fe6c28)

`double precision expansionFactor(\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the expansion factor at cosmological time `time`.

`double precision expansionFactorFromRedshift(\textcolor{red}{\textless double precision\textgreater} redshift\argin)` Returns expansion factor given a redshift.

`void expansionFactorTabulate(<double> time→)` Tabulate expansion factor as a function of cosmic time.

`double precision expansionRate(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` Returns the cosmological expansion rate, $\dot{a}/a$ at expansion factor `expansionFactor`.

`double precision exponentDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` HASH(0x1fea6a0)

`<double> exponentDarkEnergyDerivative(<double> [time]→, <double> [expansionFactor]→)` Return the derivative of the dark energy exponent with respect to expansion factor.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision hubbleParameterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Returns the Hubble parameter at the requested cosmological time, `time`, or expansion factor, `expansionFactor`.

`double precision hubbleParameterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Returns the rate of change of the Hubble parameter at the requested cosmological time, `time`, or expansion factor, `expansionFactor`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision matterDensityEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Convenience function that returns the matter density at the specified epoch.

`type(varying_string) objectType()` Return the type of the object.

`double precision omegaDarkEnergyEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Return the dark energy density parameter at expansion factor `expansionFactor`.

`double precision omegaMatterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Return the matter density parameter at expansion factor `expansionFactor`.

`double precision omegaMatterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Return the rate of change of the matter density parameter at expansion factor `expansionFactor`.

`double precision redshiftFromExpansionFactor(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` Returns redshift for a given expansion factor.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void targetSelf() Set a module-scope pointer to self.

double precision temperatureCMBEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the temperature of the cosmic microwave background at expansionFactor.

double precision timeAtDistanceComoving(\textcolor{red}{\textless double precision\textgreater} comovingDistance\argin) Return the cosmic time corresponding to the given comovingDistance.

double precision timeBigCrunch() Return the cosmological age at Big Crunch (or a negative value if no Big Crunch occurs).

cosmologyFunctionsMatterLambda

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision comovingVolumeElementRedshift(\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}z = r_\mathrm{c}^2(t)\mathrm{c}H^{-1}(t)$ (where r_c is the comoving distance to time t and $H(t)$ is the Hubble parameter at that time) for unit solid angle at the specified time.

double precision comovingVolumeElementTime(\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}t = r_\mathrm{c}^2(t)\mathrm{c}a(t)$ (where r_c is the comoving distance to time t and $a(t)$ is the expansion at that time) for unit solid angle at the specified time.

double precision cosmicTime(\textcolor{red}{\textless double precision\textgreater} expansionFactor\arg logical\textgreater} collapsingPhase\argin) Return the cosmological age at the given expansion factor.

void deepCopy(\textcolor{red}{\textless class((cosmologyFunctionsClass))\textgreater} destination\argin Perform a deep copy of the object.

void densityScalingEarlyTime(\textcolor{red}{\textless double precision\textgreater} dominateFactor\arg double precision\textgreater} densityPower\argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorDominant\argout,\textcolor{red}{\textless double precision\textgreater} OmegaDominant\argout) Compute the scaling of density with expansion factor at early times in the universe.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceAngular(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the angular diameter distance to the given cosmic `time`.

`double precision distanceComoving(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the comoving distance to the given cosmic `time`.

`double precision distanceComovingConvert(\textcolor{red}{\textless integer\textgreater} output\argin,\textcolor{red}{\textless double precision\textgreater} distanceLuminosity\argin,\text double precision\textgreater} distanceModulus\argin,\textcolor{red}{\textless double precision\textgreater} distanceModulusKCorrected\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin)` Convert between different measures of comoving distance.

`double precision distanceLuminosity(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the luminosity distance to the given cosmic `time`.

`void distanceTabulate(<double> time→)` Tabulate comoving distance as a function of cosmic time.

`double precision dominationEpochMatter(\textcolor{red}{\textless double precision\textgreater} dominateFactor\argin)` Compute the epoch at which matter dominates over other forms of energy by a given factor.

`double precision epochTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolo double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsingPhase\argin)` Convenience function that returns the time corresponding to an epoch specified by time or expansion factor.

`void epochValidate(\textcolor{red}{\textless double precision\textgreater} timeIn \argin,\textcolor{red double precision\textgreater} expansionFactorIn \argin,\textcolor{red}{\textless logical\textgreate collapsingIn \argin,\textcolor{red}{\textless double precision\textgreater} timeOut \argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorOut\argout,\textcolo logical\textgreater} collapsingOut \argout)` Check the given cosmic epoch is valid (aborting otherwise) and, optionally, return time or expansion factor associated with the epoch.

`double precision equalityEpochMatterCurvature(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-curvature magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterDarkEnergy(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-dark energy magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterRadiation(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-radiation magnitude equality (either expansion factor or cosmic time).

`double precision equationOfStateDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` HASH(0x1fe6c28)

`double precision expansionFactor(\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the expansion factor at cosmological time `time`.

`double precision expansionFactorFromRedshift(\textcolor{red}{\textless double precision\textgreater} redshift\argin)` Returns expansion factor given a redshift.

`void expansionFactorTabulate(<double> time→)` Tabulate expansion factor as a function of cosmic time.

`double precision expansionRate(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` Returns the cosmological expansion rate, $\dot{a}/a$ at expansion factor `expansionFactor`.

`double precision exponentDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` HASH(0x1fea6a0)

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision hubbleParameterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Returns the Hubble parameter at the requested cosmological time, `time`, or expansion factor, `expansionFactor`.

`double precision hubbleParameterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Returns the rate of change of the Hubble parameter at the requested cosmological time, `time`, or expansion factor, `expansionFactor`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision matterDensityEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Convenience function that returns the matter density at the specified epoch.

`type(varying_string) objectType()` Return the type of the object.

`double precision omegaDarkEnergyEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Return the dark energy density parameter at expansion factor `expansionFactor`.

`double precision omegaMatterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Return the matter density parameter at expansion factor `expansionFactor`.

`double precision omegaMatterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin)` Return the rate of change of the matter density parameter at expansion factor `expansionFactor`.

`double precision redshiftFromExpansionFactor(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` Returns redshift for a given expansion factor.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperatureCMBEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the temperature of the cosmic microwave background at expansionFactor.

double precision timeAtDistanceComoving(\textcolor{red}{\textless double precision\textgreater} comovingDistance\argin) Return the cosmic time corresponding to the given comovingDistance.

double precision timeBigCrunch() Return the cosmological age at Big Crunch (or a negative value if no Big Crunch occurs).

cosmologyFunctionsStaticUniverse

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision comovingVolumeElementRedshift(\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}z = r_\mathrm{c}^2(t)\mathrm{c}H^{-1}(t)$ (where r_c is the comoving distance to time t and $H(t)$ is the Hubble parameter at that time) for unit solid angle at the specified time.

double precision comovingVolumeElementTime(\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}t = r_\mathrm{c}^2(t)\mathrm{c}a(t)$ (where r_c is the comoving distance to time t and $a(t)$ is the expansion at that time) for unit solid angle at the specified time.

double precision cosmicTime(\textcolor{red}{\textless double precision\textgreater} expansionFactor\arg logical\textgreater} collapsingPhase\argin) Return the cosmological age at the given expansion factor.

void deepCopy(\textcolor{red}{\textless class((cosmologyFunctionsClass))\textgreater} destination\argin Perform a deep copy of the object.

void densityScalingEarlyTime(\textcolor{red}{\textless double precision\textgreater} dominateFactor\arg double precision\textgreater} densityPower\argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorDominant\argout,\textcolor{red}{\textless double precision\textgreater} OmegaDominant\argout) Compute the scaling of density with expansion factor at early times in the universe.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceAngular(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the angular diameter distance to the given cosmic `time`.

`double precision distanceComoving(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the comoving distance to the given cosmic `time`.

`double precision distanceComovingConvert(\textcolor{red}{\textless integer\textgreater} output\argin,\textcolor{red}{\textless double precision\textgreater} distanceLuminosity\argin,\text double precision\textgreater} distanceModulus\argin,\textcolor{red}{\textless double precision\textgreater} distanceModulusKCorrected\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin)` Convert between different measures of comoving distance.

`double precision distanceLuminosity(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the luminosity distance to the given cosmic `time`.

`double precision dominationEpochMatter(\textcolor{red}{\textless double precision\textgreater} dominateFactor\argin)` Compute the epoch at which matter dominates over other forms of energy by a given factor.

`double precision epochTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolo double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsingPhase\argin)` Convenience function that returns the time corresponding to an epoch specified by time or expansion factor.

`void epochValidate(\textcolor{red}{\textless double precision\textgreater} timeIn \argin,\textcolor{red double precision\textgreater} expansionFactorIn \argin,\textcolor{red}{\textless logical\textgreate collapsingIn \argin,\textcolor{red}{\textless double precision\textgreater} timeOut \argout,\textcolor{red}{\textless double precision\textgreater} expansionFactorOut\argout,\textcolo logical\textgreater} collapsingOut \argout)` Check the given cosmic epoch is valid (aborting otherwise) and, optionally, return time or expansion factor associated with the epoch.

`double precision equalityEpochMatterCurvature(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-curvature magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterDarkEnergy(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-dark energy magnitude equality (either expansion factor or cosmic time).

`double precision equalityEpochMatterRadiation(\textcolor{red}{\textless integer\textgreater} requestType\argin)` Return the epoch of matter-radiation magnitude equality (either expansion factor or cosmic time).

`double precision equationOfStateDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin)` HASH(0x1fe6c28)

`double precision expansionFactor(\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the expansion factor at cosmological time `time`.

double precision expansionFactorFromRedshift(\textcolor{red}{\textless double precision\textgreater} redshift\argin) Returns expansion factor given a redshift.

double precision expansionRate(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin) Returns the cosmological expansion rate, $\dot{a}/a$ at expansion factor expansionFactor.

double precision exponentDarkEnergy(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin) HASH(0x1fea6a0)

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision hubbleParameterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Returns the Hubble parameter at the requested cosmological time, time, or expansion factor, expansionFactor.

double precision hubbleParameterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Returns the rate of change of the Hubble parameter at the requested cosmological time, time, or expansion factor, expansionFactor.

<logical> isDefault() Return true if this is the default object of this class.

double precision matterDensityEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Convenience function that returns the matter density at the specified epoch.

type(varying_string) objectType() Return the type of the object.

double precision omegaDarkEnergyEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the dark energy density parameter at expansion factor expansionFactor.

double precision omegaMatterEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the matter density parameter at expansion factor expansionFactor.

double precision omegaMatterRateOfChange(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the rate of change of the matter density parameter at expansion factor expansionFactor.

double precision redshiftFromExpansionFactor(\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin) Returns redshift for a given expansion factor.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperatureCMBEpochal(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsingPhase\argin) Return the temperature of the cosmic microwave background at expansionFactor.

double precision timeAtDistanceComoving(\textcolor{red}{\textless double precision\textgreater} comovingDistance\argin) Return the cosmic time corresponding to the given comovingDistance.

double precision timeBigCrunch() Return the cosmological age at Big Crunch (or a negative value if no Big Crunch occurs).

cosmologyParametersClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((cosmologyParametersClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision densityCritical() Return the critical density at the present day in units of $M_\odot/\mathrm{Mpc}^3$.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision HubbleConstant(\textcolor{red}{\textless integer\textgreater} units\argin) Return the Hubble constant at the present day. The optional units argument specifies if the return value should be in units of km/s/Mpc (hubbleUnitsStandard), Gyr^{-1} (hubbleUnitsTime), or 100 km/s/Mpc (hubbleUnitsLittleH).

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision OmegaBaryon() Return the cosmological baryon density in units of the critical density at the present day.

double precision OmegaCurvature() Return the cosmological curvature density in units of the critical density at the present day.

`double precision OmegaDarkEnergy()` Return the cosmological dark energy density in units of the critical density at the present day.

`double precision OmegaMatter()` Return the cosmological matter density in units of the critical density at the present day.

`double precision OmegaRadiation()` Return the cosmological radiation density in units of the critical density at the present day.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperatureCMB()` Return the temperature of the cosmic microwave background radiation (in units of Kelvin) at the present day.

cosmologyParametersSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((cosmologyParametersClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityCritical()` Return the critical density at the present day in units of $M_\odot/\mathrm{Mpc}^3$.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision HubbleConstant(\textcolor{red}{\textless integer\textgreater} units\argin)` Return the Hubble constant at the present day. The optional `units` argument specifies if the return value should be in units of km/s/Mpc (hubbleUnitsStandard), Gyr^{-1} (hubbleUnitsTime), or 100 km/s/Mpc (hubbleUnitsLittleH).

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision OmegaBaryon()` Return the cosmological baryon density in units of the critical density at the present day.

`double precision OmegaCurvature()` Return the cosmological curvature density in units of the critical density at the present day.

`double precision OmegaDarkEnergy()` Return the cosmological dark energy density in units of the critical density at the present day.

`double precision OmegaMatter()` Return the cosmological matter density in units of the critical density at the present day.

`double precision OmegaRadiation()` Return the cosmological radiation density in units of the critical density at the present day.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperatureCMB()` Return the temperature of the cosmic microwave background radiation (in units of Kelvin) at the present day.

criticalOverdensityBarkana2001WDM

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the mass scale just collapsing at the given cosmic time.

`void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater}
criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass
\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Returns the time of collapse for a perturbation of linear theory overdensity criticalOverdensity.

double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the critical overdensity at the given time and mass.

criticalOverdensityClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the mass scale just collapsing at the given cosmic time.

void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater} criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Returns the time of collapse for a perturbation of linear theory overdensity criticalOverdensity.

double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the critical overdensity at the given time and mass.

criticalOverdensityEnvironmental

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater}
time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor
logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater}
node \arginout) Return the mass scale just collapsing at the given cosmic time.

void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater} criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Returns the time of collapse for a perturbation of linear theory overdensity criticalOverdensity.

double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout) Return the critical overdensity at the given time and mass.

criticalOverdensityFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the mass scale just collapsing at the given cosmic time.

void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout) Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout) Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater} criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Returns the time of collapse for a perturbation of linear theory overdensity criticalOverdensity.

double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout) Return the critical overdensity at the given time and mass.

criticalOverdensityKitayamaSuto1996

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the mass scale just collapsing at the given cosmic time.

void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

`double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout)` Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

`double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout)` Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Return true if the critical overdensity is dependent on the mass of the halo.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater} criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Returns the time of collapse for a perturbation of linear theory overdensity `criticalOverdensity`.

`double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout)` Return the critical overdensity at the given time and mass.

criticalOverdensityPeakBackgroundSplit

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the mass scale just collapsing at the given cosmic time.

void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater} criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Returns the time of collapse for a perturbation of linear theory overdensity criticalOverdensity.

double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the critical overdensity at the given time and mass.

criticalOverdensitySphericalCollapseMatterDE

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater}
time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor
logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater}
node \arginout) Return the mass scale just collapsing at the given cosmic time.

void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void retabulate(<double> time→)` Tabulate spherical collapse critical overdensity.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater} criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Returns the time of collapse for a perturbation of linear theory overdensity `criticalOverdensity`.

`double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout)` Return the critical overdensity at the given time and mass.

criticalOverdensitySphericalCollapseMatterLambda

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision collapsingMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the mass scale just collapsing at the given cosmic time.

`void deepCopy(\textcolor{red}{\textless class((criticalOverdensityClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision gradientMass(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout)` Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time.

`double precision gradientTime(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re type((treeNode))\textgreater} node \arginout)` Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isMassDependent() Return true if the critical overdensity is dependent on the mass of the halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void retabulate(<double> time→) Tabulate spherical collapse critical overdensity.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeOfCollapse(\textcolor{red}{\textless double precision\textgreater}
criticalOverdensity\argin,\textcolor{red}{\textless double precision\textgreater} mass
\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Returns the time of collapse for a perturbation of linear theory overdensity criticalOverdensity.

double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing \argin,\textcolor{red}{\textless double precision\textgreater} mass \argin,\textcolor{re
type((treeNode))\textgreater} node \arginout) Return the critical overdensity at the given time and mass.

darkMatterHaloBiasClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision bias(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red
double precision\textgreater} time\argin | \textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Returns the bias of a halo specified by a mass (in $M_\odot$) and time (in Gyr). | Returns the bias of the halo in the supplied node.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloBiasClass))\textgreater} destination\argin
Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterHaloBiasPressSchechter

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision bias(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red double precision\textgreater} time\argin | \textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the bias of a halo specified by a mass (in $M_\odot$) and time (in Gyr). | Returns the bias of the halo in the supplied node.

`void deepCopy(\textcolor{red}{\textless class((darkMatterHaloBiasClass))\textgreater} destination\argin` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterHaloBiasSheth2001

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision bias(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red} double precision\textgreater} time\argin | \textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the bias of a halo specified by a mass (in $M_\odot$) and time (in Gyr). | Returns the bias of the halo in the supplied node.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloBiasClass))\textgreater} destination\argin Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterHaloBiasTinker2010

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision bias(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red} double precision\textgreater} time\argin | \textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the bias of a halo specified by a mass (in $M_\odot$) and time (in Gyr). | Returns the bias of the halo in the supplied node.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloBiasClass))\textgreater} destination\argin Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterHaloMassAccretionHistoryClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassAccretionHistoryClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision time(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{
double precision\textgreater} mass\argin) Returns the time at which the given halo mass was reached.

darkMatterHaloMassAccretionHistoryCorrea2015

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassAccretionHistoryClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision time(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ double precision\textgreater} mass\argin) Returns the time at which the given halo mass was reached.

darkMatterHaloMassAccretionHistoryWechsler2002

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassAccretionHistoryClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision time(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ double precision\textgreater} mass\argin) Returns the time at which the given halo mass was reached.

darkMatterHaloMassAccretionHistoryZhao2009

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassAccretionHistoryClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision time(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{
double precision\textgreater} mass\argin) Returns the time at which the given halo mass was reached.

darkMatterHaloMassLossRateClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassLossRateClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the rate of mass loss (in $M_\odot$/Gyr) from node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterHaloMassLossRateVanDenBosch

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassLossRateClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the rate of mass loss (in $M_\odot$/Gyr) from node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterHaloMassLossRateZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloMassLossRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of mass loss (in $M_\odot$/Gyr) from node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterHaloScaleClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterHaloScaleClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision dynamicalTimescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The characteristic dynamical timescale of a dark matter halo.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision meanDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The mean density of a dark matter halo.

double precision meanDensityGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The growth rate of the mean density of a dark matter halo.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision virialRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The virial radius of a dark matter halo.

double precision virialRadiusGradientLogarithmicMass(\textcolor{red}{\textless type((treeNode))\textgre node\arginout) The logarithmic gradient of virial radius of a dark matter halo with halo mass at fixed epoch.

double precision virialRadiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The growth rate of the virial radius of a dark matter halo.

double precision virialTemperature(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The virial temperature of a dark matter halo

double precision virialVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The virial velocity of a dark matter halo

double precision virialVelocityGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The growth rate of the virial velocity of a dark matter halo.

darkMatterHaloScaleVirialDensityContrastDefinition

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

`void deepCopy(\textcolor{red}{\textless class((darkMatterHaloScaleClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision dynamicalTimescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` The characteristic dynamical timescale of a dark matter halo.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision meanDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` The mean density of a dark matter halo.

`double precision meanDensityGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` The growth rate of the mean density of a dark matter halo.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision virialRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` The virial radius of a dark matter halo.

`double precision virialRadiusGradientLogarithmicMass(\textcolor{red}{\textless type((treeNode))\textgre node\arginout)` The logarithmic gradient of virial radius of a dark matter halo with halo mass at fixed epoch.

`double precision virialRadiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` The growth rate of the virial radius of a dark matter halo.

double precision virialTemperature(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The virial temperature of a dark matter halo

double precision virialVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The virial velocity of a dark matter halo

double precision virialVelocityGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The growth rate of the virial velocity of a dark matter halo.

darkMatterParticleCDM

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterParticleClass))\textgreater} destination\argin Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterParticleClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterParticleClass))\textgreater} destination\argin Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterParticleWDMThermal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((darkMatterParticleClass))\textgreater} destination\argi` Perform a deep copy of the object.

`<double> degreesOfFreedomEffective()` Return the effective number of degrees of freedom of the thermal wark dark matter particle.

`<double> degreesOfFreedomEffectiveDecoupling()` Return the effective number of relativisitc degrees of freedom in the universe at the time at which the thermal wark dark matter particle decoupled.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`<double> mass()` Return the mass of the thermal wark dark matter particle in units of keV.

`type(varying_string) objectType()` Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileAdiabaticGnedin2004

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius
argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

<void> computeFactors(<type(treeNode)> node↔, <double> radius→, <logical> [computeGradientFactors]→) Compute factors needed for solving adiabatic contraction.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileClass))\textgreater} destination\argino Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin) Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the logarithmic slope of the density profile in the dark matter profile of node at the given radius (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate of change of total energy for the given `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot\mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<double> radiusInitial(<type(treeNode)> node↔, <double> radius→)` Compute the initial radius in the dark matter profile.

`<double> radiusInitialDerivative(<type(treeNode)> node↔, <double> radius→)` Compute the derivative of the initial radius in the dark matter profile.

`<double> radiusOrbitalMean(<double> radius→)` Compute the orbit-averaged radius for dark matter.

`<double> radiusOrbitalMeanDerivative(<double> radius→)` Compute the derivative of the orbit-averaged radius for dark matter.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileClass))\textgreater} destination\argino` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate of change of total energy for the given `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→) Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of node between the given radiusLower and radiusUpper (given in units of Mpc) using a numerical calculation.

double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←) Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of node at the given radius (given in units of Mpc) using a numerical calculation.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin) Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of node optionally between the given radiusMinimum and radiusMaximum (given in units of Mpc).

double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→) Returns the radial moment of the density in the dark matter profile of node between the given radiusMinimum and radiusMaximum (given in units of Mpc).

double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the radial velocity dispersion (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius
argin) Returns the radial velocity dispersion (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin) Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot\mathrm{Mpc}^{-3}$) in the dark matter profile of node.

double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→) Returns the radius (in Mpc) in the dark matter profile of node which encloses the given density (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin) Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of node.

double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→) Returns the radius (in Mpc) in the dark matter profile of node which encloses the given mass (given in units of $M_\odot$).

double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin Returns the radius (in Mpc) in the dark matter profile of node at which the specific angular momentum of a circular orbit equals specificAngularMomentum (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileConcentrationBullock2001

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the concentration parameter for the given `node`.

`double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the mean concentration parameter for a `node` of the given mass.

`class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition()` Returns a `darkMatterProfileDMO` object describing the dark matter density profile used to define this concentration.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`class(virialDensityContrastClass) densityContrastDefinition()` Returns a `virialDensityContrast` object describing the virial density contrast used to define this concentration.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationCorrea2015

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationDiemerKravtsov2014

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationDuttonMaccio2014

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the concentration parameter for the given `node`.

`double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the mean concentration parameter for a `node` of the given mass.

`class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition()` Returns a `darkMatterProfileDMO` object describing the dark matter density profile used to define this concentration.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`<void> definitions()` Establish definitions for virial density contrast and dark matter halo profile.

`class(virialDensityContrastClass) densityContrastDefinition()` Returns a `virialDensityContrast` object describing the virial density contrast used to define this concentration.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileConcentrationGao2008

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationKlypin2015

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationLudlow2016Fit

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

darkMatterProfileConcentrationWDM

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the concentration parameter for the given node.

double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the mean concentration parameter for a node of the given mass.

class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition() Returns a darkMatterProfileDMO object describing the dark matter density profile used to define this concentration.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this concentration.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileConcentrationZhao2009

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision concentration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the concentration parameter for the given `node`.

`double precision concentrationMean(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the mean concentration parameter for a `node` of the given mass.

`class(darkMatterProfileDMOClass) darkMatterProfileDMODefinition()` Returns a `darkMatterProfileDMO` object describing the dark matter density profile used to define this concentration.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileConcentrationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`class(virialDensityContrastClass) densityContrastDefinition()` Returns a `virialDensityContrast` object describing the virial density contrast used to define this concentration.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileDarkMatterOnly

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileClass))\textgreater} destination\argino` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate of change of total energy for the given `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in (km/s)^2) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot\mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileDMOBurkert

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`<double> angularMomentumScaleFree(<double> concentration→)` Returns the total angular momentum in an Burkert dark matter profile with given `concentration`.

`void autoHook()` Insert any event hooks required by this object.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

`double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius`
`argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`<double> densityScaleFree(<double> radius→, <double> concentration→)` Returns the density (in units such that the virial mass and scale length are unity) in a Burkert dark matter profile with given `concentration` at the given `radius` (given in units of the scale radius).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`<double> enclosedMassScaleFree(<double> radius→, <double> concentration→)` Returns the enclosed mass (in units of the virial mass) in a Burkert dark matter profile with given `concentration` at the given `radius` (given in units of the scale radius).

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→) Returns the rate of increase of the freefall radius in the dark matter density profile at the specified time (given in Gyr).

double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→) Returns the freefall radius in the dark matter density profile at the specified time (given in Gyr).

<void> freefallTabulate(<double> freefallTimeScaleFree→) Tabulates the freefall time vs. freefall radius for Burkert halos.

<double> freefallTimeScaleFree(<double> radius→) Compute the freefall time in a scale-free Burkert halo.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> inverseAngularMomentum(<double> specificAngularMomentum→) Tabulates the specific angular momentum vs. radius in an Burkert profile for rapid inversion.

<logical> isDefault() Return true if this is the default object of this class.

double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin) Returns the normalized Fourier space density profile of the dark matter profile of node at the given waveNumber (given in units of Mpc^{-1}).

double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→) Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified waveNumber (given in Mpc^{-1}).

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout) Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→) Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of node between the given radiusLower and radiusUpper (given in units of Mpc) using a numerical calculation.

double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←) Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of node at the given radius (given in units of Mpc) using a numerical calculation.

<double> profileEnergy(<double> concentration→) Computes the total energy of an Burkert profile halo of given concentration.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin) Returns the m^{th} radial moment of the dark matter profile of node optionally between the given radiusMinimum and radiusMaximum (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`<double> radialVelocityDispersionScaleFree(<double> radius→)` Returns the scale-free radial velocity dispersion in a Burkert dark matter profile.

`<void> radialVelocityDispersionTabulate(<double> radius→)` Tabulates the radial velocity dispersion vs. radius for Burkert halos.

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot \mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`<void> radiusEnclosingDensityTabulate(<double> densityScaleFree→→)` Tabulates the radius vs. enclosed density for Burkert halos.

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given node. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

double precision rotationNormalizationNumerical(<type((treeNode))> node↔) Return the normalization of the rotation velocity vs. specific angular momentum relation.

<double> specificAngularMomentumScaleFree(<double> radius→) Returns the specific angular momentum, normalized to unit scale length and unit velocity at the scale radius, at position radius (in units of the scale radius) in an Burkert profile.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> tabulate(<double> concentration→) Tabulate properties of the Burkert halo profile which must be computed numerically.

darkMatterProfileDMOClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius
argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)`
Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges`
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo`
`double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc`
`double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater}`
`status\argout)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision>`
`radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer>`
`status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te`
`double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater}`
`radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)`
Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double>`
`radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater}`
`node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)`
Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision>`
`radius`
`argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot \mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_\mathrm{rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileDMOEinasto

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`<double> densityScaleFree(<double> radius→, <double> concentration→, <double> alpha→)` Returns the density (in units such that the virial mass and scale length are unity) in an Einasto dark matter profile with given `concentration` and `alpha` at the given `radius` (given in units of the scale radius).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→) Returns the enclosed mass (in $M_\odot$) in the dark matter profile of node at the given radius (given in units of Mpc) using a numerical calculation.

<double> enclosedMassScaleFree(<double> radius→, <double> concentration→, <double> alpha→) Returns the enclosed mass (in units of the virial mass) in an Einasto dark matter profile with given concentration at the given radius (given in units of the scale radius).

double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the total energy for the given node in units of $M_\odot$ km^2 s^{-2}.

double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of chance of the total energy of node in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

double precision energyGrowthRateNumerical(<type((treeNode))> node↔) Return the rate of growth of the energy of the dark matter density profile.

double precision energyNumerical(<type((treeNode))> node↔) Return the energy of the dark matter density profile.

<void> energyTableMake(<double> concentrationRequired→, <double> alphaRequired→) Create a tabulation of the energy of Einasto profiles as a function of their concentration of α parameter.

<void> fourierProfileTableMake(<double> wavenumberRequired→, <double> concentrationRequired→, <double> alphaRequired→) Create a tabulation of the Fourier transform of Einasto profiles as a function of their α parameter and dimensionless wavenumber.

double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the freefall radius (in Mpc) corresponding to the given time (in Gyr) in node.

double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given time (in Gyr) in node.

double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→) Returns the rate of increase of the freefall radius in the dark matter density profile at the specified time (given in Gyr).

double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→) Returns the freefall radius in the dark matter density profile at the specified time (given in Gyr).

<void> freefallTabulate(<double> freefallTimeScaleFree→, <double> alphaRequired→) Tabulates the freefall time vs. freefall radius for Einasto halos.

<double> freefallTimeScaleFree(<double> radius→, <double> alpha→) Compute the freefall time in a scale-free Einasto halo.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`<double> potentialScaleFree(<double> radius→, <double> concentration→, <double> alpha→)` Returns the gravitational potential (in units where the virial mass and scale radius are unity) in an Einasto dark matter profile with given `concentration` and `alpha` at the given `radius` (given in units of the scale radius).

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`<double> radialVelocityDispersionScaleFree(<double> radius→, <double> alpha→)` Returns the scale-free radial velocity dispersion in an Einasto dark matter profile.

<void> radialVelocityDispersionTabulate(<double> radius→, <double> alphaRequired→) Tabulates the radial velocity dispersion vs. radius for Einasto halos.

double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin) Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot \mathrm{Mpc}^{-3}$) in the dark matter profile of node.

double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→) Returns the radius (in Mpc) in the dark matter profile of node which encloses the given density (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin) Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of node.

double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→) Returns the radius (in Mpc) in the dark matter profile of node which encloses the given mass (given in units of $M_\odot$).

double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin Returns the radius (in Mpc) in the dark matter profile of node at which the specific angular momentum of a circular orbit equals specificAngularMomentum (specified in units of km s^{-1} Mpc.

double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→) Returns the radius (in Mpc) in node at which a circular orbit has the given specificAngularMomentum (given in units of km s^{-1} Mpc).

<double> radiusFromSpecificAngularMomentumScaleFree(<double> alpha→, <double> specificAngularMomentumS Comptue the radius at which a circular orbit has the given specificAngularMomentumScaleFree in a scale free Einasto profile.

<void> radiusFromSpecificAngularMomentumTableMake(<double> alphaRequired→, <double> specificAngularMom Create a tabulation of the relation between specific angular momentum and radius in an Einasto profile.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given node. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

double precision rotationNormalizationNumerical(<type((treeNode))> node↔) Return the normalization of the rotation velocity vs. specific angular momentum relation.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileDMOHeated

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)
Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision>
radius
argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol
double precision\textgreater} radius\argin) Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)
Returns the logarithmic slope of the density profile in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision>
radius→) Returns the logarithmic slope of the density in the dark matter profile of node at the given radius (given in units of Mpc).

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te
double precision\textgreater} radius\argin) Returns the enclosed mass (in $M_\odot$) in the dark matter profile of node at the given radius (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\texto double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot\mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<double> radiusInitial(<*type(treeNode)> node↔, <double> radiusFinal→)` Return the initial radius corresponding to the given final radius in a heated dark matter halo density profile.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileDMOIsothermal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot \mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\mathrm{rot}} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileDMONFW

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

<double> angularMomentumScaleFree(<double> concentration→) Returns the total angular momentum in an NFW dark matter profile with given concentration.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius
argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin) Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of node at the given radius (given in units of Mpc).

<double> densityEnclosedByRadiusScaleFree(<double> radius→, <double> concentration→) Returns the density (in units of the virial mass per cubic scale radius) in an NFW dark matter profile with given concentration which is enclosed a given radius (in units of the scale radius).

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the logarithmic slope of the density profile in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→) Returns the logarithmic slope of the density in the dark matter profile of node at the given radius (given in units of Mpc).

<double> densityScaleFree(<double> radius→, <double> concentration→) Returns the density (in units such that the virial mass and scale length are unity) in an NFW dark matter profile with given concentration and alpha at the given radius (given in units of the scale radius).

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

<void> enclosedDensityTabulate(<double> enclosedDensityScaleFree→) Tabulate the density enclosed within a given radius for the NFW profile.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin) Returns the enclosed mass (in $M_\odot$) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→) Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of node between the given radiusLower and radiusUpper (given in units of Mpc) using a numerical calculation.

double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→) Returns the enclosed mass (in $M_\odot$) in the dark matter profile of node at the given radius (given in units of Mpc) using a numerical calculation.

<double> enclosedMassScaleFree(<double> radius→, <double> concentration→) Returns the enclosed mass (in units of the virial mass) in an NFW dark matter profile with given concentration at the given radius (given in units of the scale radius).

double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the total energy for the given node in units of $M_\odot$ km^2 s^{-2}.

double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of chance of the total energy of node in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

double precision energyGrowthRateNumerical(<type((treeNode))> node↔) Return the rate of growth of the energy of the dark matter density profile.

double precision energyNumerical(<type((treeNode))> node↔) Return the energy of the dark matter density profile.

double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the freefall radius (in Mpc) corresponding to the given time (in Gyr) in node.

double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin) Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given time (in Gyr) in node.

double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→) Returns the rate of increase of the freefall radius in the dark matter density profile at the specified time (given in Gyr).

double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→) Returns the freefall radius in the dark matter density profile at the specified time (given in Gyr).

<void> freefallTabulate(<double> freefallTimeScaleFree→) Tabulates the freefall time vs. freefall radius for NFW halos.

<double> freefallTimeScaleFree(<double> radius→) Compute the freefall time in a scale-free NFW halo.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> inverseAngularMomentum(<double> specificAngularMomentum→) Tabulates the specific angular momentum vs. radius in an NFW profile for rapid inversion.

<logical> isDefault() Return true if this is the default object of this class.

double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin) Returns the normalized Fourier space density profile of the dark matter profile of node at the given waveNumber (given in units of Mpc^{-1}).

double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→) Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified waveNumber (given in Mpc^{-1}).

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\texto double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout) Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→) Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of node between the given radiusLower and radiusUpper (given in units of Mpc) using a numerical calculation.

double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←) Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of node at the given radius (given in units of Mpc) using a numerical calculation.

<double> profileEnergy(<double> concentration→) Computes the total energy of an NFW profile halo of given concentration.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin) Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of node optionally between the given radiusMinimum and radiusMaximum (given in units of Mpc).

double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→) Returns the radial moment of the density in the dark matter profile of node between the given radiusMinimum and radiusMaximum (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`<double> radialVelocityDispersionScaleFree(<double> radius→, <double> concentration→)` Returns the radial velocity dispersion (in units of the virial velocity) in an NFW dark matter profile with given `concentration` at the given `radius` (given in units of the scale radius).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot \mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

<double> specificAngularMomentumScaleFree(<double> radius→) Returns the specific angular momentum, normalized to unit scale length and unit velocity at the scale radius, at position radius (in units of the scale radius) in an NFW profile.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> tabulate(<double> concentration→) Tabulate properties of the NFW halo profile which must be computed numerically.

darkMatterProfileDMOTruncated

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius
argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin) Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the logarithmic slope of the density profile in the dark matter profile of node at the given radius (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot\mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void truncationFunction(<type(treeNode)> node↔, <double> radius→, <double> [x]←, <double> [multiplier]←, <double> [multiplierGradient]←)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

darkMatterProfileDMOTruncatedExponential

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

double precision circularVelocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision circularVelocityMaximum(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔) Returns the maximum circular velocity (in km/s) in the dark matter profile of node.

double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius
argin) Returns the circular velocity (in km/s) in the dark matter profile of node at the given radius (given in units of Mpc).

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin) Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Returns the logarithmic slope of the density profile in the dark matter profile of node at the given radius (given in units of Mpc).

double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→) Returns the logarithmic slope of the density in the dark matter profile of node at the given radius (given in units of Mpc).

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin) Returns the enclosed mass (in $M_\odot$) in the dark matter profile of node at the given radius (given in units of Mpc).

double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→) Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of node between the given radiusLower and radiusUpper (given in units of Mpc) using a numerical calculation.

double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→) Returns the enclosed mass (in $M_\odot$) in the dark matter profile of node at the given radius (given in units of Mpc) using a numerical calculation.

double precision energy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the total energy for the given node in units of $M_\odot$ km^2 s^{-2}.

`double precision energyGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`.

`double precision freeFallRadiusIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} time\argin)` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpace(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo double precision\textgreater} wavenumber\argin)` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}).

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textc double precision\textgreater} radius\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in (km/s)^2) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin)` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersion(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} density\argin)` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot\mathrm{Mpc}^{-3}$) in the dark matter profile of `node`.

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} mass\argin)` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`.

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentum(\textcolor{red}{\textless type((treeNode))\textgreat node\arginout,\textcolor{red}{\textless double precision\textgreater} specificAngularMomentum\argin` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc.

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void truncationFunction(<type(treeNode)> node↔, <double> radius→, <double> [x]←, <double> [multiplier]←, <double> [multiplierGradient]←)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

darkMatterProfileGeneric

`double precision circularVelocityMaximumNumerical(<type((treeNode))> node↔)` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`.

`double precision circularVelocityNumerical(<type((treeNode))> node↔,<double precision> radius`
`argin)` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision density(<type((treeNode))> node↔,<double precision> radius→)` Returns the density (in $M_\odot$/Mpc^3) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision densityLogSlopeNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the logarithmic slope of the density in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMass(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision enclosedMassDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the enclosed mass difference (in $M_\odot$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision enclosedMassNumerical(<type((treeNode))> node↔,<double precision> radius→)` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision energyGrowthRateNumerical(<type((treeNode))> node↔)` Return the rate of growth of the energy of the dark matter density profile.

`double precision energyNumerical(<type((treeNode))> node↔)` Return the energy of the dark matter density profile.

`double precision freefallRadiusIncreaseRateNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the rate of increase of the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`double precision freefallRadiusNumerical(<type((treeNode))> node↔,<double precision> time→)` Returns the freefall radius in the dark matter density profile at the specified `time` (given in Gyr).

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision kSpaceNumerical(<type((treeNode))> node↔, <double> waveNumber→)` Returns the Fourier transform of the adiabaticGnedin2004 density profile at the specified `waveNumber` (given in Mpc^{-1}).

`double precision potentialDifferenceNumerical(<type((treeNode))> node↔, <double precision> radiusLower→, <double precision> radiusUpper→)` Returns the gravitational potential difference (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` between the given `radiusLower` and `radiusUpper` (given in units of Mpc) using a numerical calculation.

`double precision potentialNumerical(<type((treeNode))> node↔,<double precision> radius→,<integer> status←)` Returns the gravitational potential (in $(\mathrm{km/s})^2$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc) using a numerical calculation.

`double precision radialMomentNumerical(<type((treeNode))> node↔, <double> moment→, <double> radiusMinimum→, <double> radiusMaximum→)` Returns the radial moment of the density in the dark matter profile of `node` between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc).

`double precision radialVelocityDispersionNumerical(<type((treeNode))> node↔,<double precision> radius`
`argin)` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc).

`double precision radiusEnclosingDensityNumerical(<type((treeNode))> node↔,<double precision> density→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `density` (given in units of $M_\odot/\mathrm{Mpc}^{-3}$).

`double precision radiusEnclosingMassNumerical(<type((treeNode))> node↔,<double precision> mass→)` Returns the radius (in Mpc) in the dark matter profile of `node` which encloses the given `mass` (given in units of $M_\odot$).

`double precision radiusFromSpecificAngularMomentumNumerical(<type((treeNode))> node↔,<double precision> specificAngularMomentum→)` Returns the radius (in Mpc) in `node` at which a circular orbit has the given `specificAngularMomentum` (given in units of km s^{-1} Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalizationNumerical(<type((treeNode))> node↔)` Return the normalization of the rotation velocity vs. specific angular momentum relation.

darkMatterProfileHeatingClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileHeatingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision specificEnergy(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` The specific energy of heating at the given `radius` in the given `node`.

`double precision specificEnergyGradient(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` The gradient of the specific energy of heating at the given `radius` in the given `node`.

`logical specificEnergyIsEverywhereZero(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout)` Returns true if the specific energy is zero everywhere in the given `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileHeatingNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileHeatingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision specificEnergy(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) The specific energy of heating at the given radius in the given node.

double precision specificEnergyGradient(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) The gradient of the specific energy of heating at the given radius in the given node.

logical specificEnergyIsEverywhereZero(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout) Returns true if the specific energy is zero everywhere in the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileHeatingSummation

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileHeatingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision specificEnergy(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` The specific energy of heating at the given `radius` in the given `node`.

`double precision specificEnergyGradient(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` The gradient of the specific energy of heating at the given `radius` in the given `node`.

`logical specificEnergyIsEverywhereZero(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout)` Returns true if the specific energy is zero everywhere in the given `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileHeatingTidal

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileHeatingClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision specificEnergy(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater}
darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater}
radius\argin) The specific energy of heating at the given radius in the given node.

double precision specificEnergyGradient(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater}
darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater}
radius\argin) The gradient of the specific energy of heating at the given radius in the given node.

logical specificEnergyIsEverywhereZero(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater}
darkMatterProfileDMO_\arginout) Returns true if the specific energy is zero everywhere in the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileHeatingTwoBodyRelaxation

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileHeatingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision specificEnergy(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` The specific energy of heating at the given `radius` in the given `node`.

`double precision specificEnergyGradient(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` The gradient of the specific energy of heating at the given `radius` in the given `node`.

`logical specificEnergyIsEverywhereZero(\textcolor{red}{\textless type((treeNode ))\textgreater} node\arginout,\textcolor{red}{\textless class((darkMatterProfileDMOClass))\textgreater} darkMatterProfileDMO_\arginout)` Returns true if the specific energy is zero everywhere in the given `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileScaleRadiusBinary

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileScaleRadiusClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the scale radius for the given node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileScaleRadiusClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileScaleRadiusClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the scale radius for the given node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileScaleRadiusConcentration

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileScaleRadiusClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the scale radius for the given node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileScaleRadiusLudlow2014

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileScaleRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

<double> formationTimeRoot(<double> timeFormation→) Evalute a function which goes to zero at the formation time of the tree.

<void> formationTimeRootFunctionSet(<type(rootFinder)> finder↔) Initialize a root finder object for use in finding the formation time of the tree.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the scale radius for the given node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileScaleRadiusLudlow2016

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileScaleRadiusClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

<double> formationTimeRoot(<double> timeFormation→) Evalute a function which goes to zero at the formation time of the tree.

<void> formationTimeRootFunctionSet(<type(rootFinder)> finder↔) Initialize a root finder object for use in finding the formation time of the tree.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the scale radius for the given node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileScaleRadiusZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileScaleRadiusClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the scale radius for the given `node`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

darkMatterProfileShapeClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileShapeClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision shape(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the shape parameter for the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileShapeGao2008

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((darkMatterProfileShapeClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision shape(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the shape parameter for the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

darkMatterProfileShapeKlypin2015

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((darkMatterProfileShapeClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision shape(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the shape parameter for the given `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

differentiator

`double precision derivative(<double> x→, <double> [h]←, <double> [errorAbsolute]←)` Returns the derivative of the function at argument `x`.

distributionFunction1DBeta

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DCauchy

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin) Return the probability density at x.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin) Return the value of the independent variable corresponding to cumulative probability p.

<logical> isDefault() Return true if this is the default object of this class.

double precision maximum() Returns the maximum possible value in the distribution.

double precision minimum() Returns the minimum possible value in the distribution.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom))\textgreater} randomNumberGenera Return a random deviate from the distribution.

void samplerReset() Reset the sampler for the distribution.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

distributionFunction1DClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin) Return the cumulative probability at x.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DGamma

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DLogNormal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DLogUniform

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DNegativeExponential

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DNormal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DPeakBackground

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DStudentT

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin) Return the probability density at x.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin) Return the value of the independent variable corresponding to cumulative probability p.

<logical> isDefault() Return true if this is the default object of this class.

double precision maximum() Returns the maximum possible value in the distribution.

double precision minimum() Returns the minimum possible value in the distribution.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom))\textgreater} randomNumberGenera Return a random deviate from the distribution.

void samplerReset() Reset the sampler for the distribution.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

distributionFunction1DUniform

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin) Return the cumulative probability at x.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunction1DVoight

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunction1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless double precision\textgreater} x\argin)` Return the probability density at `x`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision maximum()` Returns the maximum possible value in the distribution.

`double precision minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{r logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunctionDiscrete1DBinomial

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunctionDiscrete1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`integer inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision mass(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the probability mass at `x`.

`double precision massLogarithmic(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the logarithm of the probability mass at `x`.

`integer maximum()` Returns the maximum possible value in the distribution.

`integer minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`integer sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{red}{\text logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunctionDiscrete1DClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunctionDiscrete1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`integer inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision mass(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the probability mass at `x`.

`double precision massLogarithmic(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the logarithm of the probability mass at `x`.

`integer maximum()` Returns the maximum possible value in the distribution.

`integer minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`integer sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{red}{\text logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

distributionFunctionDiscrete1DNegativeBinomial

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cumulative(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the cumulative probability at `x`.

`void deepCopy(\textcolor{red}{\textless class((distributionFunctionDiscrete1DClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`integer inverse(\textcolor{red}{\textless double precision\textgreater} p\argin)` Return the value of the independent variable corresponding to cumulative probability `p`.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision mass(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the probability mass at `x`.

`double precision massLogarithmic(\textcolor{red}{\textless integer\textgreater} x\argin)` Return the logarithm of the probability mass at `x`.

`integer maximum()` Returns the maximum possible value in the distribution.

`integer minimum()` Returns the minimum possible value in the distribution.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`integer sample(\textcolor{red}{\textless integer\textgreater} incrementSeed\argin,\textcolor{red}{\text logical\textgreater} ompThreadOffset\argin,\textcolor{red}{\textless logical\textgreater} mpiRankOffset\argin,\textcolor{red}{\textless type((pseudoRandom ))\textgreater} randomNumberGenera` Return a random deviate from the distribution.

`void samplerReset()` Reset the sampler for the distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

doubleScalarHash

<void> delete(<(character(len=*)|varying_string)> key→, <integer> value→) Delete a key from the hash.

void destroy() Destroy the hash.

<logical> exists(<(character(len=*)|varying_string|<integer>)> key→) Return true if the specified key exists in the hash.

<void> initialize() Initialize the hash.

<type(varying_string)> key(<integer> indexValue→) Return the key of the indexValue$^{\text{th}}$ entry in the hash.

<void> keys(<type(varying_string)[:]> keys↔) Return an array of all keys in the hash.

<void> set(<(character(len=*)|varying_string)> key→, <integer> value→) Set the value of a key in the hash.

<integer> size() Return the number of keys in the hash.

<integer> value(<(character(len=*)|varying_string|<integer>)> key→, <integer> value→) Return the value for the given key.

<void> values(<double precision[:]> values↔) Return an array of all values in the hash.

eventHook

<integer> count() Return a count of the number of hooks into this event.

HASH(0x1c7ece8) first(<*type(hook)>) Return a pointer to the first hook into this event.

HASH(0x1c83d80) initialize() Initialize the event.

void lock() Lock the event.

void unlock() Unlock the event.

eventHook88992e2a75a1ab33893e7a1e2bf92b3d

<void> attach(<class(*)> *object_→, <procedure()> *function_→) Attach a hook to the event.

<integer> count() Return a count of the number of hooks into this event.

<void> detach(<class(*)> *object_→, <procedure()> *function_→) Detach a hook from the event.

HASH(0x1c7ece8) first(<*type(hook)>) Return a pointer to the first hook into this event.

HASH(0x1c83d80) initialize() Initialize the event.

void lock() Lock the event.

void unlock() Unlock the event.

eventHookUnspecified

<void> attach(<class(*)> *object_→, <procedure()> *function_→) Attach a hook to the event.

<integer> count() Return a count of the number of hooks into this event.

<void> detach(<class(*)> *object_→, <procedure()> *function_→) Detach a hook from the event.

HASH(0x1c7ece8) first(<*type(hook)>) Return a pointer to the first hook into this event.

HASH(0x1c83d80) initialize() Initialize the event.

void lock() Lock the event.

void unlock() Unlock the event.

evolveForestsWorkShareClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((evolveForestsWorkShareClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

integer(c_size_t) forestNumber(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argi
Return the number of the forest to process.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer workerCount(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin) Return the count of workers.

integer workerID(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin) Return a unique worker ID.

evolveForestsWorkShareCyclic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((evolveForestsWorkShareClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

integer(c_size_t) forestNumber(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argi Return the number of the forest to process.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer workerCount(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin) Return the count of workers.

integer workerID(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin) Return a unique worker ID.

evolveForestsWorkShareFCFS

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((evolveForestsWorkShareClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

integer(c_size_t) forestNumber(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argi
Return the number of the forest to process.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer workerCount(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin)
Return the count of workers.

integer workerID(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin)
Return a unique worker ID.

evolveForestsWorkShareStride

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((evolveForestsWorkShareClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`integer(c_size_t) forestNumber(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argi` Return the number of the forest to process.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`integer workerCount(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin)` Return the count of workers.

`integer workerID(\textcolor{red}{\textless logical\textgreater} utilizeOpenMPThreads\argin)` Return a unique worker ID.

excursionSetBarrierClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision barrier(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textco double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin)` Return the barrier height at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise.

`double precision barrierGradient(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin)` Return the gradient of the barrier with respect to variance at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise.

`void deepCopy(\textcolor{red}{\textless class((excursionSetBarrierClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

excursionSetBarrierCriticalOverdensity

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision barrier(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textco double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin)` Return the barrier height at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise.

`double precision barrierGradient(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin)` Return the gradient of the barrier with respect to variance at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise.

`void deepCopy(\textcolor{red}{\textless class((excursionSetBarrierClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

excursionSetBarrierLinear

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision barrier(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textco
double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin) Return the barrier height at the given variance and time. The rateCompute should be set to true if the barrier is being used in a calculation of barrier crossing rates, and to false otherwise.

double precision barrierGradient(\textcolor{red}{\textless double precision\textgreater}
variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\
type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater}
rateCompute\argin) Return the gradient of the barrier with respect to variance at the given variance and time. The rateCompute should be set to true if the barrier is being used in a calculation of barrier crossing rates, and to false otherwise.

void deepCopy(\textcolor{red}{\textless class((excursionSetBarrierClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

excursionSetBarrierQuadratic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision barrier(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textco double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin) Return the barrier height at the given variance and time. The rateCompute should be set to true if the barrier is being used in a calculation of barrier crossing rates, and to false otherwise.

double precision barrierGradient(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin) Return the gradient of the barrier with respect to variance at the given variance and time. The rateCompute should be set to true if the barrier is being used in a calculation of barrier crossing rates, and to false otherwise.

void deepCopy(\textcolor{red}{\textless class((excursionSetBarrierClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

excursionSetBarrierRemapScale

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision barrier(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textco double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin) Return the barrier height at the given variance and time. The rateCompute should be set to true if the barrier is being used in a calculation of barrier crossing rates, and to false otherwise.

double precision barrierGradient(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin) Return the gradient of the barrier with respect to variance at the given variance and time. The rateCompute should be set to true if the barrier is being used in a calculation of barrier crossing rates, and to false otherwise.

void deepCopy(\textcolor{red}{\textless class((excursionSetBarrierClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

excursionSetBarrierRemapShethMoTormen

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision barrier(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcc double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin)` Return the barrier height at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise.

`double precision barrierGradient(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} rateCompute\argin)` Return the gradient of the barrier with respect to variance at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise.

`void deepCopy(\textcolor{red}{\textless class((excursionSetBarrierClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

excursionSetFirstCrossingClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void coordinatedMPI(\textcolor{red}{\textless logical\textgreater} state\argin)` Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes.

`void deepCopy(\textcolor{red}{\textless class((excursionSetFirstCrossingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision probability(\textcolor{red}{\textless double precision\textgreater} variance\argin,\te double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the probability for a trajectory to make its first crossing of the barrier at the given `variance` and `time`.

`double precision rate(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor double precision\textgreater} varianceProgenitor\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate of first crossing for excursion sets beginning at the given `variance` and `time` to transition to a first crossing at the given `varianceProgenitor`.

`double precision rateNonCrossing(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout)` Return the rate of non-crossing for excursion sets beginning at the given `variance` and `time`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

excursionSetFirstCrossingFarahi

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void coordinatedMPI(\textcolor{red}{\textless logical\textgreater} state\argin)` Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes.

`void deepCopy(\textcolor{red}{\textless class((excursionSetFirstCrossingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`<void> fileRead()` Read excursion set solutions from file.

`<void> fileWrite()` Write excursion set solutions to file.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision probability(\textcolor{red}{\textless double precision\textgreater} variance\argin,\te double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the probability for a trajectory to make its first crossing of the barrier at the given `variance` and `time`.

`double precision rate(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor double precision\textgreater} varianceProgenitor\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate of first crossing for excursion sets beginning at the given `variance` and `time` to transition to a first crossing at the given `varianceProgenitor`.

`double precision rateNonCrossing(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout)` Return the rate of non-crossing for excursion sets beginning at the given `variance` and `time`.

`<void> rateTabulate(<double> varianceProgenitor→, <double> time→)` Tabulate excursion set barrier crossing rates ensuring that they span the given progenitor variance and time.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double(:)> varianceRange(<double> rangeMinimum→, <double> rangeMaximum→, <integer> rangeNumber, <double> exponent) Build a range of variances at which to tabulate the excursion set solutions.

excursionSetFirstCrossingFarahiMidpoint

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void coordinatedMPI(\textcolor{red}{\textless logical\textgreater} state\argin) Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes.

void deepCopy(\textcolor{red}{\textless class((excursionSetFirstCrossingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

<void> fileRead() Read excursion set solutions from file.

<void> fileWrite() Write excursion set solutions to file.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision probability(\textcolor{red}{\textless double precision\textgreater} variance\argin,\te double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the probability for a trajectory to make its first crossing of the barrier at the given variance and time.

double precision rate(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor double precision\textgreater} varianceProgenitor\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate of first crossing for excursion sets beginning at the given variance and time to transition to a first crossing at the given varianceProgenitor.

double precision rateNonCrossing(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\type((treeNode))\textgreater} node\arginout) Return the rate of non-crossing for excursion sets beginning at the given variance and time.

<void> rateTabulate(<double> varianceProgenitor→, <double> time→) Tabulate excursion set barrier crossing rates ensuring that they span the given progenitor variance and time.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double(:)> varianceRange(<double> rangeMinimum→, <double> rangeMaximum→, <integer> rangeNumber, <double> exponent) Build a range of variances at which to tabulate the excursion set solutions.

excursionSetFirstCrossingLinearBarrier

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void coordinatedMPI(\textcolor{red}{\textless logical\textgreater} state\argin) Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes.

void deepCopy(\textcolor{red}{\textless class((excursionSetFirstCrossingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision probability(\textcolor{red}{\textless double precision\textgreater} variance\argin,\te double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the probability for a trajectory to make its first crossing of the barrier at the given variance and time.

double precision rate(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor double precision\textgreater} varianceProgenitor\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate of first crossing for excursion sets beginning at the given variance and time to transition to a first crossing at the given varianceProgenitor.

double precision rateNonCrossing(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout) Return the rate of non-crossing for excursion sets beginning at the given variance and time.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

excursionSetFirstCrossingZhangHui

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void coordinatedMPI(\textcolor{red}{\textless logical\textgreater} state\argin) Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes.

void deepCopy(\textcolor{red}{\textless class((excursionSetFirstCrossingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

<double> delta(<integer> i→, <integer> j→,<double> iVariance→, <double> jVariance→, <double> deltaVariance→, <double> time→) Returns the function $g_2(S, S')$ integrated over a range ΔS [Zhang and Hui, 2006].

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

<double> g1(<double> variance→, <double> time→) Returns the function $g_1(S)$ [Zhang and Hui, 2006].

<double> g2(<double> variance→, <double> variancePrimed→, <double> time→) Returns the function $g_2(S, S')$ [Zhang and Hui, 2006].

<double> g2Integrated(<double> variance→, <double> deltaVariance→, <double> time→) Returns the function $g_2(S, S')$ integrated over a range ΔS [Zhang and Hui, 2006].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision probability(\textcolor{red}{\textless double precision\textgreater} variance\argin,\te double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the probability for a trajectory to make its first crossing of the barrier at the given variance and time.

double precision rate(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor double precision\textgreater} varianceProgenitor\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate of first crossing for excursion sets beginning at the given variance and time to transition to a first crossing at the given varianceProgenitor.

double precision rateNonCrossing(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout) Return the rate of non-crossing for excursion sets beginning at the given variance and time.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

excursionSetFirstCrossingZhangHuiHighOrder

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

`void coordinatedMPI(\textcolor{red}{\textless logical\textgreater} state\argin)` Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes.

`void deepCopy(\textcolor{red}{\textless class((excursionSetFirstCrossingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`<double> delta(<integer> i→, <integer> j→,<double> iVariance→, <double> jVariance→, <double> deltaVariance→, <double> time→)` Returns the function $g_2(S, S')$ integrated over a range ΔS [Zhang and Hui, 2006].

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`<double> g1(<double> variance→, <double> time→)` Returns the function $g_1(S)$ [Zhang and Hui, 2006].

`<double> g2(<double> variance→, <double> variancePrimed→, <double> time→)` Returns the function $g_2(S, S')$ [Zhang and Hui, 2006].

`<double> g2Integrated(<double> variance→, <double> deltaVariance→, <double> time→)` Returns the function $g_2(S, S')$ integrated over a range ΔS [Zhang and Hui, 2006].

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize the high order Zhang and Hui [2006] class.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision probability(\textcolor{red}{\textless double precision\textgreater} variance\argin,\te double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the probability for a trajectory to make its first crossing of the barrier at the given `variance` and `time`.

`double precision rate(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor double precision\textgreater} varianceProgenitor\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate of first crossing for excursion sets beginning at the given `variance` and `time` to transition to a first crossing at the given `varianceProgenitor`.

`double precision rateNonCrossing(\textcolor{red}{\textless double precision\textgreater} variance\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\ type((treeNode))\textgreater} node\arginout)` Return the rate of non-crossing for excursion sets beginning at the given `variance` and `time`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

fastExponentiator

<double> exponentiate(<double> x→) Evaluate x^y using table look-up.

freefallRadiusClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((freefallRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the freefall radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc.

double precision radiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of increase of the freefall radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

freefallRadiusDarkMatterHalo

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((freefallRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the freefall radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc.

double precision radiusGrowthRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of increase of the freefall radius for gas in the hot atmosphere surrounding the galaxy in node in units of Mpc/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

freefallTimeAvailableClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((freefallTimeAvailableClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeAvailable(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the time available for freefall in cooling calculations in node.

double precision timeAvailableIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate at which the time available for freefall in cooling calculations increases in node.

freefallTimeAvailableHaloFormation

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((freefallTimeAvailableClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeAvailable(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the time available for freefall in cooling calculations in node.

double precision timeAvailableIncreaseRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate at which the time available for freefall in cooling calculations increases in node.

functionClass

<logical> isDefault() Return true if this is the default object of this class.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

galacticDynamicsBarInstabilityClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticDynamicsBarInstabilityClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\t double precision\textgreater} timescale\argout,\textcolor{red}{\textless double precision\textgreat externalDrivingSpecificTorque\argout) Returns a timescale on which the bar instability depletes material from a disk into a pseudo-bulge. A negative value indicates no instability. Also returns the net torque due to any external force causing this instability.

galacticDynamicsBarInstabilityEfstathiou1982

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticDynamicsBarInstabilityClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

<double> estimator() Compute the stability estimator for the Efstathiou et al. [1982] model for galactic disk bar instability.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\t double precision\textgreater} timescale\argout,\textcolor{red}{\textless double precision\textgreat externalDrivingSpecificTorque\argout)` Returns a timescale on which the bar instability depletes material from a disk into a pseudo-bulge. A negative value indicates no instability. Also returns the net torque due to any external force causing this instability.

galacticDynamicsBarInstabilityEfstathiou1982Tidal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((galacticDynamicsBarInstabilityClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`<double> estimator()` Compute the stability estimator for the Efstathiou et al. [1982] model for galactic disk bar instability.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<double> tidalTensorRadial()` Compute the radial term of the tidal tensor.

`void timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\t double precision\textgreater} timescale\argout,\textcolor{red}{\textless double precision\textgreat externalDrivingSpecificTorque\argout)` Returns a timescale on which the bar instability depletes material from a disk into a pseudo-bulge. A negative value indicates no instability. Also returns the net torque due to any external force causing this instability.

galacticDynamicsBarInstabilityFixedTimescale

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticDynamicsBarInstabilityClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\t
double precision\textgreater} timescale\argout,\textcolor{red}{\textless double precision\textgreat
externalDrivingSpecificTorque\argout) Returns a timescale on which the bar instability depletes material from a disk into a pseudo-bulge. A negative value indicates no instability. Also returns the net torque due to any external force causing this instability.

galacticDynamicsBarInstabilityStable

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticDynamicsBarInstabilityClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\t double precision\textgreater} timescale\argout,\textcolor{red}{\textless double precision\textgreat externalDrivingSpecificTorque\argout)` Returns a timescale on which the bar instability depletes material from a disk into a pseudo-bulge. A negative value indicates no instability. Also returns the net torque due to any external force causing this instability.

galacticFilterAll

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((galacticFilterClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical passes(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return true if the given `node` passes the filter.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

galacticFilterAlways

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void deepCopy(\textcolor{red}{\textless class((galacticFilterClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

logical passes(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return true if the given node passes the filter.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

galacticFilterTreeHosted

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((galacticFilterClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical passes(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return true if the given `node` passes the filter.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

galacticStructureSolverClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((galacticStructureSolverClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void revert(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Revert the structure of components in the given node (if necessary to ensure that the structure solver will give the same result when called consecutively).

void solve(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Solves for the structure of components in the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

galacticStructureSolverEquilibrium

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticStructureSolverClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void revert(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Revert the structure of components in the given node (if necessary to ensure that the structure solver will give the same result when called consecutively).

void solve(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Solves for the structure of components in the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

galacticStructureSolverFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticStructureSolverClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void revert(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Revert the structure of components in the given node (if necessary to ensure that the structure solver will give the same result when called consecutively).

void solve(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Solves for the structure of components in the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

galacticStructureSolverLinear

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((galacticStructureSolverClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void revert(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Revert the structure of components in the given node (if necessary to ensure that the structure solver will give the same result when called consecutively).

void solve(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Solves for the structure of components in the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

galacticStructureSolverSimple

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((galacticStructureSolverClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void revert(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Revert the structure of components in the given `node` (if necessary to ensure that the structure solver will give the same result when called consecutively).

`void solve(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Solves for the structure of components in the given `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

gauntFactorClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((gauntFactorClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision total(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin) Returns the thermally averaged, total Gaunt factor.

gauntFactorSutherland1998

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((gauntFactorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision total(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin) Returns the thermally averaged, total Gaunt factor.

gauntFactorVanHoof2014

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((gauntFactorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision total(\textcolor{red}{\textless integer\textgreater} atomicNumber\argin,\textcolor{red integer\textgreater} electronNumber\argin,\textcolor{red}{\textless double precision\textgreater} temperature\argin) Returns the thermally averaged, total Gaunt factor.

genericScalarHash

<void> delete(<(character(len=*)|varying_string)> key→, <integer> value→) Delete a key from the hash.

void destroy() Destroy the hash.

<logical> exists(<(character(len=*)|varying_string|<integer>)> key→) Return true if the specified key exists in the hash.

<void> initialize() Initialize the hash.

<type(varying_string)> key(<integer> indexValue→) Return the key of the indexValue$^{\text{th}}$ entry in the hash.

<void> keys(<type(varying_string)[:]> keys↔) Return an array of all keys in the hash.

<void> set(<(character(len=*)|varying_string)> key→, <integer> value→) Set the value of a key in the hash.

<integer> size() Return the number of keys in the hash.

<integer> value(<(character(len=*)|varying_string|<integer>)> key→, <integer> value→) Return the value for the given key.

<void> values(<class(*), pointer[:]> values↔) Return an array of all values in the hash.

geometryLightconeClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((geometryLightconeClass))\textgreater} destination\argino Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isInLightcone(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ logical\textgreater} atPresentEpoch\argin,\textcolor{red}{\textless double precision\textgreater} radiusBuffer\argin) Returns true if the provided node lies within the lightcone.

type(varying_string) objectType() Return the type of the object.

double precision, dimension(3) position(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} instance\argin) Returns the position vector of a node (in units of Mpc) in the lightcone coordinate system.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

integer(c_size_t) replicationCount(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the number of times the given nodes appears in the lightone .

double precision solidAngle() Returns the solid angle subtended by the lightcone (in units of steradians).

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision, dimension(3) velocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} instance\argin)` Returns the velocity vector of a `node` (in units of km/s) in the lightcone coordinate system.

geometryLightconeSquare

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((geometryLightconeClass))\textgreater} destination\argino` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isInLightcone(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ logical\textgreater} atPresentEpoch\argin,\textcolor{red}{\textless double precision\textgreater} radiusBuffer\argin)` Returns true if the provided node lies within the lightcone.

`type(varying_string) objectType()` Return the type of the object.

`double precision, dimension(3) position(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} instance\argin)` Returns the position vector of a `node` (in units of Mpc) in the lightcone coordinate system.

`<double(3)> positionAtOutput(<integer> output→, <double(3)> nodePosition→, <logical> [positionFound]←)` Returns the position of a point, `nodePosition` (given in physical coordinates within the primary replicant volume), in comoving coordinates in the replicant volume in which it appears in the lightcone. If the point is *not* in the lightcone the returned position is set to the largest possible negative number in each coordinate. If the optional `positionFound` argument is given it will be set to true or false to indicate whether or not the point was found in the lightcone volume.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

<void> replicants(<integer> output→, <double(3)> nodePosition→, <replicantAction> action→, <integer> [count]←, <logical> [isInLightcone],<integer> [instance]→, <double(3)> [position]←) Performs various actions related to replicants of nodes appearing in lightcone output, depending on the value of the action argument:

- replicantActionCount returns in count the number of replicants in which the node appears in the lightcone;
- replicantActionAny returns true in isInLightcone if the given position appears in *any* replicant in the lightcone;
- replicantActionInstance returns in position the position in the instance$^{\text{th}}$ replicant in which this position appears in the lightcone.

integer(c_size_t) replicationCount(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the number of times the given nodes appears in the lightone .

double precision solidAngle() Returns the solid angle subtended by the lightcone (in units of steradians).

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision, dimension(3) velocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} instance\argin) Returns the velocity vector of a node (in units of km/s) in the lightcone coordinate system.

gravitationalLensingBaryonicModifier

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((gravitationalLensingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

`double precision magnificationCDF(\textcolor{red}{\textless double precision\textgreater} magnification\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin,\textcol double precision\textgreater} scaleSource\argin)` Returns the cumulative probability function for magnification.

`double precision magnificationPDF(\textcolor{red}{\textless double precision\textgreater} magnification\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin,\textcol double precision\textgreater} scaleSource\argin)` Returns the differential probability function for magnification.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`<void> renormalize(<double> redshift→, <double> scaleSource→)` Renormalize the gravitational lensing magnification distribution function.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

gravitationalLensingClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((gravitationalLensingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision magnificationCDF(\textcolor{red}{\textless double precision\textgreater} magnification\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin,\textcol double precision\textgreater} scaleSource\argin)` Returns the cumulative probability function for magnification.

double precision magnificationPDF(\textcolor{red}{\textless double precision\textgreater} magnification\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin,\textcol double precision\textgreater} scaleSource\argin) Returns the differential probability function for magnification.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

gravitationalLensingTakahashi2011

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double> convergenceDistribution(<double> convergence→) Returns the gravitational lensing convergence probability density function at the given convergence.

void deepCopy(\textcolor{red}{\textless class((gravitationalLensingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

<void> lensingDistributionConstruct(<double> redshift→, <double> scaleSource→) Construct the gravitational lensing distribution functions for the specified redshift and source scale.

double precision magnificationCDF(\textcolor{red}{\textless double precision\textgreater} magnification\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin,\textcol double precision\textgreater} scaleSource\argin) Returns the cumulative probability function for magnification.

double precision magnificationPDF(\textcolor{red}{\textless double precision\textgreater} magnification\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin,\textcol double precision\textgreater} scaleSource\argin) Returns the differential probability function for magnification.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloEnvironmentClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

double precision cdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin) Return the cumulative distribution function (CDF) of the environmental overdensity for the given overdensity.

void deepCopy(\textcolor{red}{\textless class((haloEnvironmentClass))\textgreater} destination\arginout Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision environmentMass() Return the mean mass contained in the region used to defined the environmental.

double precision environmentRadius() Return the radius of the region used to defined the environmental.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

`double precision overdensityLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} presentDay\argin)` Return the environmental linear overdensity for the given `node`.

`double precision overdensityLinearMaximum()` Return the maximum linear overdensity for which the environmental overdensity probability density function (PDF) is non-zero.

`double precision overdensityLinearMinimum()` Return the minimum linear overdensity for which the environmental overdensity PDF is non-zero.

`void overdensityLinearSet(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Set the environmental overdensity for the give node.

`double precision overdensityNonLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the environmental non-linear overdensity for the given `node`.

`double precision pdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Return the PDF of the environmental overdensity for the given overdensity.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloEnvironmentLogNormal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\textcolor{red}{\textless character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Return the CDF of the environmental overdensity for the given overdensity.

`void deepCopy(\textcolor{red}{\textless class((haloEnvironmentClass))\textgreater} destination\arginout` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision environmentMass()` Return the mean mass contained in the region used to defined the environmental.

`double precision environmentRadius()` Return the radius of the region used to defined the environmental.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision overdensityLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} presentDay\argin)` Return the environmental linear overdensity for the given `node`.

`double precision overdensityLinearMaximum()` Return the maximum linear overdensity for which the environmental overdensity PDF is non-zero.

`double precision overdensityLinearMinimum()` Return the minimum linear overdensity for which the environmental overdensity PDF is non-zero.

`void overdensityLinearSet(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textco double precision\textgreater} overdensity\argin)` Set the environmental overdensity for the give node.

`double precision overdensityNonLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the environmental non-linear overdensity for the given `node`.

`double precision pdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Return the PDF of the environmental overdensity for the given overdensity.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloEnvironmentNormal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Return the CDF of the environmental overdensity for the given overdensity.

void deepCopy(\textcolor{red}{\textless class((haloEnvironmentClass))\textgreater} destination\arginout Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision environmentMass() Return the mean mass contained in the region used to defined the environmental.

double precision environmentRadius() Return the radius of the region used to defined the environmental.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision overdensityLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} presentDay\argin) Return the environmental linear overdensity for the given node.

double precision overdensityLinearMaximum() Return the maximum linear overdensity for which the environmental overdensity PDF is non-zero.

double precision overdensityLinearMinimum() Return the minimum linear overdensity for which the environmental overdensity PDF is non-zero.

void overdensityLinearSet(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textco double precision\textgreater} overdensity\argin) Set the environmental overdensity for the give node.

double precision overdensityNonLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the environmental non-linear overdensity for the given node.

double precision pdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin) Return the PDF of the environmental overdensity for the given overdensity.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloEnvironmentUniform

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`double precision cdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Return the CDF of the environmental overdensity for the given overdensity.

`void deepCopy(\textcolor{red}{\textless class((haloEnvironmentClass))\textgreater} destination\arginout` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision environmentMass()` Return the mean mass contained in the region used to defined the environmental.

`double precision environmentRadius()` Return the radius of the region used to defined the environmental.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision overdensityLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless logical\textgreater} presentDay\argin)` Return the environmental linear overdensity for the given `node`.

`double precision overdensityLinearMaximum()` Return the maximum linear overdensity for which the environmental overdensity PDF is non-zero.

`double precision overdensityLinearMinimum()` Return the minimum linear overdensity for which the environmental overdensity PDF is non-zero.

`void overdensityLinearSet(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcc double precision\textgreater} overdensity\argin)` Set the environmental overdensity for the give node.

`double precision overdensityNonLinear(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the environmental non-linear overdensity for the given `node`.

`double precision pdf(\textcolor{red}{\textless double precision\textgreater} overdensity\argin)` Return the PDF of the environmental overdensity for the given overdensity.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloMassFunctionBhattacharya2011

`<double> a(<double> time→, <double> mass→)` Return the parameter $\bar{a}$ in the Bhattacharya et al. [2011] halo mass function fit.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the differential halo mass function for `mass` [$M_\odot$] at `time` [Gyr].

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the halo mass function at `time` [Gyr] integrated between `massLow` and `massHigh` [$M_\odot$].

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the halo mass fraction at `time` [Gyr] integrated between `massLow` and `massHigh` [$M_\odot$].

`<double> normalization(<double> time→, <double> mass→)` Return the parameter $\bar{A}$ in the Bhattacharya et al. [2011] halo mass function fit.

`type(varying_string) objectType()` Return the type of the object.

`<double> p(<double> time→, <double> mass→)` Return the parameter $\bar{p}$ in the Bhattacharya et al. [2011] halo mass function fit.

`<double> q(<double> time→, <double> mass→)` Return the parameter $\bar{q}$ in the Bhattacharya et al. [2011] halo mass function fit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass $[M_\odot]$ at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh $[M_\odot]$.

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh $[M_\odot]$.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionDespali2015

<double> a(<double> time→, <double> mass→) Return the parameter a in the Sheth et al. [2001] halo mass function fit.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<double> normalization(<double> time→, <double> mass→) Return the parameter A in the Sheth et al. [2001] halo mass function fit.

type(varying_string) objectType() Return the type of the object.

<double> p(<double> time→, <double> mass→) Return the parameter p in the Sheth et al. [2001] halo mass function fit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> x(<double> time→, <double> mass→) Return the parameter x in the Despali et al. [2015] halo mass function fit.

haloMassFunctionEnvironmental

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionEnvironmentAveraged

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionErrorConvolved

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionFofBias

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass $[M_\odot]$ at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh $[M_\odot]$.

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh $[M_\odot]$.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionPressSchechter

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the differential halo mass function for `mass` [$M_\odot$] at `time` [Gyr].

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the halo mass function at `time` [Gyr] integrated between `massLow` and `massHigh` [$M_\odot$].

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)` Return the halo mass fraction at `time` [Gyr] integrated between `massLow` and `massHigh` [$M_\odot$].

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloMassFunctionRodriguezPuebla2016

<double> a(<double> time→, <double> mass→) Return the parameter a in the Tinker et al. [2008] halo mass function fit.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double> b(<double> time→, <double> mass→) Return the parameter b in the Tinker et al. [2008] halo mass function fit.

<double> c(<double> time→, <double> mass→) Return the parameter c in the Tinker et al. [2008] halo mass function fit.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater}
node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol
double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater}
massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)
Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater}
massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)
Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<double> normalization(<double> time→, <double> mass→) Return the parameter A in the Tinker et al. [2008] halo mass function fit.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionShethTormen

<double> a(<double> time→, <double> mass→) Return the parameter a in the Sheth et al. [2001] halo mass function fit.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<double> normalization(<double> time→, <double> mass→) Return the parameter A in the Sheth et al. [2001] halo mass function fit.

type(varying_string) objectType() Return the type of the object.

<double> p(<double> time→, <double> mass→) Return the parameter p in the Sheth et al. [2001] halo mass function fit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionSimpleSystematic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionTinker2008

<double> a(<double> time→, <double> mass→) Return the parameter a in the Tinker et al. [2008] halo mass function fit.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double> b(<double> time→, <double> mass→) Return the parameter b in the Tinker et al. [2008] halo mass function fit.

<double> c(<double> time→, <double> mass→) Return the parameter c in the Tinker et al. [2008] halo mass function fit.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<double> normalization(<double> time→, <double> mass→) Return the parameter A in the Tinker et al. [2008] halo mass function fit.

type(varying_string) objectType() Return the type of the object.

<void> parametersEvaluate(<double> time→, <double> mass→) Evaluate hyper-parameters needed for the fitting function.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionTinker2008Form

<double> a(<double> time→, <double> mass→) Return the parameter a in the Tinker et al. [2008] halo mass function fit.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double> b(<double> time→, <double> mass→) Return the parameter b in the Tinker et al. [2008] halo mass function fit.

<double> c(<double> time→, <double> mass→) Return the parameter c in the Tinker et al. [2008] halo mass function fit.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout) Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater}
massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)
Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<double> normalization(<double> time→, <double> mass→) Return the parameter A in the Tinker et al. [2008] halo mass function fit.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloMassFunctionTinker2008Generic

<double> a(<double> time→, <double> mass→) Return the parameter a in the Tinker et al. [2008] halo mass function fit.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double> b(<double> time→, <double> mass→) Return the parameter b in the Tinker et al. [2008] halo mass function fit.

<double> c(<double> time→, <double> mass→) Return the parameter c in the Tinker et al. [2008] halo mass function fit.

void deepCopy(\textcolor{red}{\textless class((haloMassFunctionClass))\textgreater} destination\arginou
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc
double precision\textgreater} mass\argin,\textcolor{red}{\textless type((treeNode))\textgreater}
node \arginout) Return the differential halo mass function for mass [$M_\odot$] at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol
double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater}
massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)
Return the halo mass function at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<logical> isDefault() Return true if this is the default object of this class.

double precision massFraction(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto
double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater}
massHigh\argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout)
Return the halo mass fraction at time [Gyr] integrated between massLow and massHigh [$M_\odot$].

<double> normalization(<double> time→, <double> mass→) Return the parameter A in the Tinker et al. [2008] halo mass function fit.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloModelPowerSpectrumModifierClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloModelPowerSpectrumModifierClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

void modify(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textcolor{red}{\t
integer\textgreater} term\argin,\textcolor{red}{\textless double precision\textgreater}
powerSpectrum\arginout,\textcolor{red}{\textless double precision\textgreater} powerSpectrumCovaria
double precision\textgreater} mass\argin) Modify the power spectra in the halo model of clustering.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloModelPowerSpectrumModifierIdentity

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((haloModelPowerSpectrumModifierClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`void modify(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textcolor{red}{\t integer\textgreater} term\argin,\textcolor{red}{\textless double precision\textgreater} powerSpectrum\arginout,\textcolor{red}{\textless double precision\textgreater} powerSpectrumCovaria double precision\textgreater} mass\argin)` Modify the power spectra in the halo model of clustering.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloModelPowerSpectrumModifierTriaxiality

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((haloModelPowerSpectrumModifierClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`void modify(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textcolor{red}{\t integer\textgreater} term\argin,\textcolor{red}{\textless double precision\textgreater} powerSpectrum\arginout,\textcolor{red}{\textless double precision\textgreater} powerSpectrumCovaria double precision\textgreater} mass\argin)` Modify the power spectra in the halo model of clustering.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloSpinDistributionBett2007

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((haloSpinDistributionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distribution(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the spin distribution function, $p(\lambda)$, for the given `node`. It is assumed that `node` provides the value of the spin at which the distribution function should be evaluated.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision sample(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Samples a spin parameter from the distribution for the given `node`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

haloSpinDistributionClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((haloSpinDistributionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distribution(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the spin distribution function, $p(\lambda)$, for the given `node`. It is assumed that `node` provides the value of the spin at which the distribution function should be evaluated.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision sample(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Samples a spin parameter from the distribution for the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloSpinDistributionDeltaFunction

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloSpinDistributionClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision distribution(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return the spin distribution function, $p(\lambda)$, for the given node. It is assumed that node provides the value of the spin at which the distribution function should be evaluated.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision sample(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Samples a spin parameter from the distribution for the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloSpinDistributionLogNormal

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloSpinDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision distribution(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the spin distribution function, $p(\lambda)$, for the given node. It is assumed that node provides the value of the spin at which the distribution function should be evaluated.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision sample(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Samples a spin parameter from the distribution for the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

haloSpinDistributionNbodyErrors

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((haloSpinDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision distribution(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the spin distribution function, $p(\lambda)$, for the given node. It is assumed that node provides the value of the spin at which the distribution function should be evaluated.

<double> distributionAveraged(<*type(treeNode)> node↔, <double> massLimit→) Return the spin distribution function averaged over all halos above the given massLimit.

<double> distributionFixedPoint(<*type(treeNode)> node↔, <double> spinMeasured→) Return the spin distribution function at a fixed point in intrinsic mass and spin.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision sample(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Samples a spin parameter from the distribution for the given node.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> tabulate(<double> [massRequired]→, <double> [spinRequired]→) Tabulate the spin distribution as a fuction of spin and halo mass. Ensure that the table spans the massRequired and spinRequireed if provided.

hashPerfect

<void> create(<integer(kind=kind_int8)(:)> keys→, <integer(kind=kind_int8)(:)> [values]→, <logical>[keepInverseTable]→) Create a perfect hash.

<void> destroy() Destroy a perfect hash.

<integer(kind=kind_int8)> index(<integer(kind=kind_int8)> key→) Return the index corresponding to a key in a perfect hash.

<logical> isPresent(<integer(kind=kind_int8)> key→) Test if a key is present in a perfect hash.

<integer(kind=kind_int8)> size() Return the size of a perfect hash.

<integer(kind=kind_int8)> value(<integer(kind=kind_int8)> key→) Return the value corresponding to a key in a perfect hash.

hdf5Object

<void> assertAttributeType(<integer(kind=HID_T)(:)> attributeAssertedType→, <integer> attributeAssertedRank→, [matches]←) Check the type and rank of an attribute.

<void> assertDatasetType(<integer(kind=HID_T)(:)> datasetAssertedType→, <integer> datasetAssertedRank
Check the type and rank of a dataset.

<void> close() Close an HDF5 object.

<type(hdf5Object copy() Copy an HDF5 object.

<void> createReference1D(<type(hdf5Object)> toDataset↔, <character(len=*)> referenceName→, <integer(kind=HSIZE_T)(1)> referenceStart→, <integer(kind=HSIZE_T)(1)> referenceCount→) Create a reference to a 1D dataset.

<void> createReference2D(<type(hdf5Object)> toDataset↔, <character(len=*)> referenceName→, <integer(kind=HSIZE_T)(2)> referenceStart→, <integer(kind=HSIZE_T)(2)> referenceCount→) Create a reference to a 2D dataset.

<void> createReference3D(<type(hdf5Object)> toDataset↔, <character(len=*)> referenceName→, <integer(kind=HSIZE_T)(3)> referenceStart→, <integer(kind=HSIZE_T)(3)> referenceCount→) Create a reference to a 2D dataset.

<void> createReference4D(<type(hdf5Object)> toDataset↔, <character(len=*)> referenceName→, <integer(kind=HSIZE_T)(4)> referenceStart→, <integer(kind=HSIZE_T)(4)> referenceCount→) Create a reference to a 2D dataset.

<void> createReference5D(<type(hdf5Object)> toDataset↔, <character(len=*)> referenceName→, <integer(kind=HSIZE_T)(5)> referenceStart→, <integer(kind=HSIZE_T)(5)> referenceCount→) Create a reference to a 2D dataset.

<type(varying_string)> datasetNames(:) datasets() Get a list of datasets in a group object.

<void> deepCopy(<type(hdf5Object) destination←) Create a deep copy of the object with a new HDF5 object identifier.

<void> destroy() Destroy an HDF5 object.

<void> flush() Flush an HDF5 file to disk.

`<logical> hasAttribute(<character(len=*)> [attributeName]→)` Check if an object has a named attribute.

`<logical> hasDataset(<character(len=*)> [datasetName]→)` Check if an object has a named dataset.

`<logical> hasGroup(<character(len=*)> [groupName]→)` Check if an object has a named group.

`<logical> isOpen()` Return true if an object is open.

`<logical> isReference()` Return true if a dataset is a reference.

`<type(varying_string)> name()` Returns the name of a given object.

`<integer> objectType()` Return the object type.

`<type(hdf5Object openAttribute(<character(len=*)> attributeName→, <integer> [attributeDataType]→, <integer(kind=HSIZE_T)(:)> [attributeDimensions]→, <logical> [isOverwritable]→, <integer(kind=HID T)> [useDataType]→)` Open an HDF5 attribute.

`<type(hdf5Object openDataset(<character(len=*)> datasetName→, <character(len=*)> [commentText]→, <integer> [datasetDataType]→, <integer(kind=HSIZE_T)(:)> [datasetDimensions]→, <logical> [isOverwritable]→, <logical> [appendTo]→, <integer(kind=HID_T)> [useDataType]→, <integer> [chunkSize]→, <integer> [compressionLevel]→)` Open an HDF5 dataset.

`<void> openFile(<character(len=*)> [fileName], <logical> [overWrite]→, <logical> [readOnly]→, <logical> [objectsOverwritable]→, <integer> [chunkSize]→, <integer> [compressionLevel]→)` Open an HDF5 file and return an appropriate HDF5 object.

`<type(hdf5Object openGroup(<character(len=*)> groupName→, <character(len=*)> [commentText]→, <logical> [overWrite]→, <logical> [objectsOverwritable]→, <integer> [chunkSize]→, <integer> [compressionLevel]→)` Open an HDF5 group and return an appropriate HDF5 object.

`<void> parent(<character(len=*)> objectName→, <type(hdf5Object) target↔)` Return the parent object.

`<type(varying_string)> pathTo()` Returns the path to a given object.

`<integer> rank()` Return the rank of a dataset.

`<void> readAttribute(<character(len=*)> [attributeName]→), <(integer|integer(kind=kind_int8)|double|character(len=*)|type(varying_string))[:^{0-1}*]) > attributeValue←, <logical>[allowPseu` Read an attribute from an HDF5 object.

`<void> readAttributeStatic(<character(len=*)> [attributeName]→), <(integer|integer(kind=kind_int8)|double|character(len=*)|type(varying_string))[:^{0-1}]) > attributeValue←, <logical>[allowPseud` Read an attribute from an HDF5 object into a static array.

`<void> readDataset(<character(len=*)> [datasetName]→), <(integer|integer(kind=kind_int8)|double|charac string))[:^{0-1}*]) > datasetValue←, <integer(kind=HSIZE_T)[1]> [readBegin]→, <integer(kind=HSIZE_T)[1]> [readCount]→)` Read a dataset from an HDF5 group into an allocatable array.

`<void> readDatasetStatic(<character(len=*)> [datasetName]→, <(integer|integer(kind=kind_int8)|double|character(len=*)|type(varying_string))[:^{0-1}]) > datasetValue←, <integer(kind=HSIZE_T)[1]> [readBegin]→, <integer(kind=HSIZE_T)[1]> [readCount]→)` Read a dataset from an HDF5 group into a static array.

<void> readTable(<character(len=*)> [tableName]→), <character(len=*)> [columnName]→), <(integer|integer(kind=kind_int8)|double|character(len=*))[:$^{0-1}$*]) > datasetValue←, <integer(kind=HSIZE_T)[1]> [readBegin]→, <integer(kind=HSIZE_T)[1]> [readCount]→) Read a column from an HDF5 table into an allocatable array.

<integer(kind=HSIZE_T)> size(<integer> dim→) Return the size of a dataset.

<void> writeAttribute(<(integer|integer(kind=kind_int8)|double|character(len=*)|type(varying_string))(|[:])) > attributeValue→, <character(len=*)> [attributeName]→)) Write an attribute to an HDF5 object.

<void> writeDataset(<(integer|integer(kind=kind_int8)|double|character(len=*)|type(varying_string))[:$^{0-14}$]) > datasetValue→, <character(len=*)> [datasetName]→), <character(len=*)> [commentText]→, <logical>[appendTo]→, <integer>[chunkSize]→, <integer>[compressionLevel]→, <type(hdf5Object [datasetReturned]←) Write a dataset to an HDF5 group.

history

<type(history)> add(<type(history)> + <type(history)>) Addition operator.

<void> append((<double> time→, <double(:)> append→| <type(history)> append→)) Append a history or single instant onto the end of a history.

<void> builder(<*type(node)> historyDefinition→) Build a history object from an XML definition.

<void> clone(<type(history)> historyToClone→) Clone a history object.

<void> create(<integer> historyCount→, <integer> timesCount→, <double> [timeBegin]→, <double> [timeEnd]→, <integer> [rangeType]→) Creates a history object with a specified range of times.

<void> deserialize(<double(:)> historyArray→) Deserialize a history object from an array.

<void> destroy(<type(history)> historyToClone→) Destroys a history object.

<type(history)> divide(<type(history)> / <type(history)>) Division operator.

<void> dump() Dump a history object.

<void> dumpRaw(<integer> fileHandle→) Dump a history object in binary.

<logical> exists() Returns true if the given history has been created.

<void> extend(<double(2)> [timeRange]→, <double(:)> [times]→) Extends the time range of a history to encompass the specified limits.

<void> increment(<type(history)> addHistory→) Adds two histories, possibly with different time series.

<void> interpolatedIncrement(<type(history)> addHistory→) Adds two histories, possibly with different time series, by interpolating the second onto the times of the first and adding the interpolated values.

[4]For `double` datasets, up to 5-dimensional datasets are supported.

<logical> isZero() Returns true if the history is entirely zero.

<type(history)> multiply(<type(history)> * <type(history)>) Multiplication operator.

<integer(c_size_t) > nonStaticSizeOf() Returns the size of any non-static components of the type.

<void> readRaw(<integer> fileHandle→) Read a history object in binary.

<void> reset() Resets all entries in a history to zero.

<void> serialize(<double(:)> historyArray←) Serialize a history object to an array.

<integer> serializeCount() Return a count of the number of properties in a serialized history object.

<void> setToUnity() Set all entries in a history to unity.

<type(history)> subtract(<type(history)> - <type(history)>) Subtraction operator.

<void> timeSteps(<double(:)> timeSteps←) Returns an array with the timesteps (i.e. the intervals between successive times) in the given history.

<void> trim(<double> currentTime→, <integer> [minimumPointsToRemove]→) Removes any times in a history which have become outdated.

<void> trimForward(<double> currentTime→, <type(history)> [removedHistory]←) Removes any times in a history *after* the given time. Optionally returns a history object with the removed history.

hotHaloColdModeCoreRadiiClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloColdModeCoreRadiiClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return the core radius of the hot halo mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloColdModeCoreRadiiVirialFraction

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloColdModeCoreRadiiClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the core radius of the hot halo mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionBetaProfile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the logarithmic slope of the density of the hot halo at the given radius.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin) Return the mass enclosed in the hot halo at the given radius.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

void initialize(<*type(treeNode)> node→) Initialize the β-profile density hot halo mass distribution for the given node.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for node. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol
double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)
Return the logarithmic slope of the density of the hot halo at the given radius.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te
double precision\textgreater} radius\argin) Return the mass enclosed in the hot halo at the given radius.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te
double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater}
radius\argin) Return the density of the hot halo at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for node. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionCoreRadiusClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionCoreRadiusClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the core radius of the hot halo mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionCoreRadiusGrowing

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionCoreRadiusClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the core radius of the hot halo mass distribution.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloMassDistributionCoreRadiusVirialFraction

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionCoreRadiusClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radius(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the core radius of the hot halo mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionEnzoHydrostatic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the logarithmic slope of the density of the hot halo at the given radius.

<double> densityNormalization(<*type(treeNode)> node↔) Return the normalization of the density profile.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the hot halo at the given radius.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for node. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the logarithmic slope of the density of the hot halo at the given radius.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin) Return the mass enclosed in the hot halo at the given radius.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the density of the hot halo at the given `radius`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloMassDistributionPatejLoeb2015

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol double precision\textgreater} radius\argin)` Return the density of the hot halo at the given `radius`.

`double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the logarithmic slope of the density of the hot halo at the given `radius`.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} radius\argin)` Return the mass enclosed in the hot halo at the given `radius`.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te
double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater}
radius\argin) Return the density of the hot halo at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for node. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloMassDistributionRicotti2000

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloMassDistributionClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcol
double precision\textgreater} radius\argin) Return the density of the hot halo at the given radius.

double precision densityLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)
Return the logarithmic slope of the density of the hot halo at the given radius.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision enclosedMass(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te
double precision\textgreater} radius\argin) Return the mass enclosed in the hot halo at the given radius.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`void initialize(<*type(treeNode)> node→)` Initialize the β-profile density hot halo mass distribution for the given `node`.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radialMoment(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\te double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the density of the hot halo at the given `radius`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision rotationNormalization(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloOutflowReincorporationClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloOutflowReincorporationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the rate at which outflowed mass is being reincorporated into the hot halo.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloOutflowReincorporationHaloDynamicalTime

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloOutflowReincorporationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the rate at which outflowed mass is being reincorporated into the hot halo.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloOutflowReincorporationHenriques2013

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloOutflowReincorporationClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return the rate at which outflowed mass is being reincorporated into the hot halo.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloOutflowReincorporationVelocityMaximumScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((hotHaloOutflowReincorporationClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return the rate at which outflowed mass is being reincorporated into the hot halo.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloOutflowReincorporationZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloOutflowReincorporationClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return the rate at which outflowed mass is being reincorporated into the hot halo.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloRamPressureForceClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureForceClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision force(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the ram pressure force acting on `node` (in units of $(\mathrm{km/s})^2 M_\odot/\mathrm{Mpc}^3$).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloRamPressureForceFont2008

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureForceClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision force(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the ram pressure force acting on `node` (in units of $(\mathrm{km/s})^2 M_\odot/\mathrm{Mpc}^3$).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloRamPressureForceZero

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureForceClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision force(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the ram pressure force acting on `node` (in units of $(\mathrm{km/s})^2 M_\odot/\mathrm{Mpc}^3$).

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloRamPressureStrippingClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureStrippingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radiusStripped(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the radius to which node is stripped due to ram pressure from its host halo (in units of Mpc).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloRamPressureStrippingFont2008

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureStrippingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision radiusStripped(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the radius to which `node` is stripped due to ram pressure from its host halo (in units of Mpc).

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

hotHaloRamPressureStrippingVirialRadius

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureStrippingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision radiusStripped(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the radius to which node is stripped due to ram pressure from its host halo (in units of Mpc).

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

hotHaloRamPressureTimescaleClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureTimescaleClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the ram pressure stripping timescale for node (in units of Gyr).

hotHaloRamPressureTimescaleHaloDynamicalTime

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureTimescaleClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the ram pressure stripping timescale for node (in units of Gyr).

hotHaloRamPressureTimescaleRamPressureAcceleration

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloRamPressureTimescaleClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the ram pressure stripping timescale for node (in units of Gyr).

hotHaloTemperatureProfileClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloTemperatureProfileClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperature(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex
double precision\textgreater} radius\argin) Return the temperature of the hot halo at the given radius.

double precision temperatureLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)
Return the logarithmic slope of the temperature of the hot halo at the given radius.

hotHaloTemperatureProfileEnzoHydrostatic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloTemperatureProfileClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperature(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} radius\argin) Return the temperature of the hot halo at the given radius.

double precision temperatureLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the logarithmic slope of the temperature of the hot halo at the given radius.

hotHaloTemperatureProfileVirial

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((hotHaloTemperatureProfileClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

`double precision temperature(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} radius\argin)` Return the temperature of the hot halo at the given `radius`.

`double precision temperatureLogSlope(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the logarithmic slope of the temperature of the hot halo at the given `radius`.

importerUnits

`<logical> areEqual(<type(importerUnits)> units2→)` Return true if the provided units are equal.

`<logical> areNotEqual(<type(importerUnits)> units2→)` Return true if the provided units are not equal.

`<type(importerUnits)> exponentiate(<integer>exponent→)` Raise to the given integer power.

`<type(importerUnits)> multiply(<type(importerUnits)> units2→)` Multiply by another `importerUnits` object.

initialMassFunctionBaugh2005TopHeavy

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) label()` Return the label for this IMF.

`double precision massMaximum()` Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass M =`massInitial`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout) Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$massInitial.

initialMassFunctionBPASS

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) label() Return the label for this IMF.

double precision massMaximum() Return the maximum mass in the initial mass function.

double precision massMinimum() Return the minimum mass in the initial mass function.

type(varying_string) objectType() Return the type of the object.

double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin) Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$massInitial.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

initialMassFunctionChabrier2001

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) label()` Return the label for this IMF.

`double precision massMaximum()` Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

initialMassFunctionClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) label()` Return the label for this IMF.

`double precision massMaximum()` Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

initialMassFunctionKennicutt1983

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) label()` Return the label for this IMF.

`double precision massMaximum()` Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

initialMassFunctionKroupa2001

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) label() Return the label for this IMF.

double precision massMaximum() Return the maximum mass in the initial mass function.

double precision massMinimum() Return the minimum mass in the initial mass function.

type(varying_string) objectType() Return the type of the object.

double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)
Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$massInitial.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)
Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$initialMass.

initialMassFunctionMillerScalo1979

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) label() Return the label for this IMF.

double precision massMaximum() Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

initialMassFunctionPiecewisePowerLaw

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) label()` Return the label for this IMF.

`double precision massMaximum()` Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout) Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$initialMass.

initialMassFunctionSalpeter1955

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) label() Return the label for this IMF.

double precision massMaximum() Return the maximum mass in the initial mass function.

double precision massMinimum() Return the minimum mass in the initial mass function.

type(varying_string) objectType() Return the type of the object.

double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin) Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$massInitial.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

initialMassFunctionScalo1986

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((initialMassFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) label()` Return the label for this IMF.

`double precision massMaximum()` Return the maximum mass in the initial mass function.

`double precision massMinimum()` Return the minimum mass in the initial mass function.

`type(varying_string) objectType()` Return the type of the object.

`double precision phi(\textcolor{red}{\textless double precision\textgreater} massInitial\argin)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulate(\textcolor{red}{\textless class((table1D))\textgreater} imfTable\arginout)` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`.

inputParameter

<void> destroy() Destroy this parameter and all subparameters.

<void> get() Return the value of this parameter in a simple textual context.

<logical> isParameter() Return true if this is a valid parameter node.

<logical> objectCreated() Return true the object corresponding to this parameter has been created.

<*class(functionClass)> objectGet() Return a pointer to the object corresponding to this parameter.

<void> objectSet(<*class(functionClass)> object→, <logical> isShared→) Set a pointer to the object corresponding to this parameter.

<void> reset() Reset all objects in this parameter and any sub-parameters.

<void> set(<double> value→) Set the value of this parameter.

inputParameterList

<void> add(<character(len=*)> name→, <character(len=*)> value→) Add a parameter and value to the list.

<void> serializeToXML() Serialize a list of input parameters to an XML document.

inputParameters

<void> addParameter(<character(len=*)> parameterName→, <character(len=*)> parameterValue→) Add a parameter.

<void> buildTree(<type(inputParameter)> *parentParameter↔, <type(node)> *parametersNode→) Build a tree of inputParameter objects from the structure of an XML parameter file.

<void> checkParameters(<type(varying_string)[:]> [allowedParameterNames]→) Check that parameters are valid and, optionally, check if they match expected names in the provided list.

<integer> copiesCount(<character(len=*)> parameterName→, <logical>[zeroIfNotPresent]→) Return a count of the number copies of the named parameter. If the parameter is not present, this function aborts, unless zeroIfNotPresent is set to true, in which case a result of 0 is returned.

<integer> count(<character(len=*)> parameterName→, <logical>[zeroIfNotPresent]→) Return a count of the number of values in the named parameter. If the parameter is not present, this function aborts, unless zeroIfNotPresent is set to true, in which case a result of 0 is returned.

<void> destroy() Destroy the parameters document.

<logical> isGlobal() Return true if these parameters are the global set.

<logical> isPresent(<character(len=*)> parameterName→) Return true if the named parameter is present in the set.

<void> markGlobal() Mark an input parameter set as the global set.

<type(node)> node(<character(len=*)> parameterName→) Return the XML node containing the named parameter.

<void> parametersGroupCopy(<class(inputParameters)> inputParameters_→) Copy the HDF5 output group for parameters from another parameters object.

<void> parametersGroupOpen(<type(hdf5Object)> outputGroup↔) Open an output group for parameters in the given HDF5 object.

<void> reset() Reset all objects in this parameter set.

<void> resolveReferences() Resolve references in the tree of inputParameter objects.

<type(varying_string)> serializeToString() Serialize input parameters to a string.

<void> serializeToXML(<type(varying_string)> parameterFile→) Serialize input parameters to an XML file.

<type(inputParameters)> subParameters(<character(len=*)> parameterName→) Return the set of subparameters of the named parameter.

<void> validateName(<character(len=*)> parameterName→) Check that a given parameter name is a valid name, aborting if not.

<void> value((<*> parameterName|<node> parameterNode)→, parameterValue, (<*> [defaultValue])→, <inputParameterErrorStatus>[errorStatus]←, <logical>[writeOutput]→) Return the value of a parameter specified by name or XML node. A default value can be specified only if the parameter is specified by name. Supported types include rank-0 and rank-1 logicals, integers, long integers, doubles, characters, and varying strings.

integerScalarHash

<void> delete(<(character(len=*)|varying_string)> key→, <integer> value→) Delete a key from the hash.

void destroy() Destroy the hash.

<logical> exists(<(character(len=*)|varying_string|<integer>)> key→) Return true if the specified key exists in the hash.

<void> initialize() Initialize the hash.

<type(varying_string)> key(<integer> indexValue→) Return the key of the indexValue$^{\text{th}}$ entry in the hash.

<void> keys(<type(varying_string)[:]> keys↔) Return an array of all keys in the hash.

<void> set(<(character(len=*)|varying_string)> key→, <integer> value→) Set the value of a key in the hash.

<integer> size() Return the number of keys in the hash.

<integer> value(<(character(len=*)|varying_string|<integer>)> key→, <integer> value→) Return the value for the given key.

<void> values(<integer[:]> values↔) Return an array of all values in the hash.

integerSizeTScalarHash

<void> delete(<(character(len=*)|varying_string)> key→, <integer> value→) Delete a key from the hash.

void destroy() Destroy the hash.

<logical> exists(<(character(len=*)|varying_string|<integer>)> key→) Return true if the specified key exists in the hash.

<void> initialize() Initialize the hash.

<type(varying_string)> key(<integer> indexValue→) Return the key of the indexValue$^{\text{th}}$ entry in the hash.

<void> keys(<type(varying_string)[:]> keys↔) Return an array of all keys in the hash.

<void> set(<(character(len=*)|varying_string)> key→, <integer> value→) Set the value of a key in the hash.

<integer> size() Return the number of keys in the hash.

<integer> value(<(character(len=*)|varying_string|<integer>)> key→, <integer> value→) Return the value for the given key.

<void> values(<integer(c_size_t)[:]> values↔) Return an array of all values in the hash.

integrator

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integrator1D

<double> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> integrandSet(<procedure(<double> (<double> x→))> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorAdaptiveCompositeTrapezoidal1D

<double> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> initialize(<integer> iterationsMaximum→) Set the maximum number of iterations allowed in the integrator.

<void> integrandSet(<procedure(<double> (<double> x→))> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorCompositeGaussKronrod1D

<double> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> evaluateInterval(<double> a→, <double> b→, <double> integralKronrod←, <double> error←) Evaluate the integral over an interval and also return the error on the integral.

<void> initialize(<integer> iterationsMaximum→, <integer> order→) Initialize the integrator.

<void> integrandSet(<procedure(<double> (<double> x→))> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorCompositeTrapezoidal1D

<double> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> initialize(<integer> iterationsMaximum→) Set the maximum number of iterations allowed in the integrator.

<void> integrandSet(<procedure(<double> (<double> x→))> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorMulti

<void> tolerancesSet(<double(:)> [toleranceAbsolute]→, <double(:)> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorMulti1D

<double(:)> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> integrandSet(<integer> integrandCount→, <procedure(<double> (<double> x→))> integrand→) Set the integrand function to be integrated.

<void> tolerancesSet(<double(:)> [toleranceAbsolute]→, <double(:)> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorMultiVectorized1D

<void> integrandSet(<integer> integrandCount→, <<double(:)> function(doubleone x→)> integrand→) Set the integrand function to be integrated.

<void> tolerancesSet(<double(:)> [toleranceAbsolute]→, <double(:)> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorMultiVectorizedCompositeGaussKronrod1D

<void> evaluate(<double> a→, <double> b→, <double(:)> integral←) Evaluate the integrals.

<void> evaluateInterval(<double> a→, <double> b→, <double(:)> integralKronrod←, <double(:)> error←) Evaluate the integrals over an interval and also return errors on the integrals.

<void> initialize(<integer> intervalsMaximum→, <integer> order→) Set the maximum number of intervals allowed, and the order of the integrator.

<void> integrandSet(<integer> integrandCount→, <<double(:)> function(doubleone x→)> integrand→) Set the integrand function to be integrated.

<void> tolerancesSet(<double(:)> [toleranceAbsolute]→, <double(:)> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorMultiVectorizedCompositeTrapezoidal1D

<void> evaluate(<double> a→, <double> b→, <double(:)> integral←) Evaluate the integrals.

<void> initialize(<integer> intervalsMaximum→) Set the maximum number of intervals allowed.

<void> integrandSet(<integer> integrandCount→, <<double(:)> function(doubleone x→)> integrand→) Set the integrand function to be integrated.

<void> tolerancesSet(<double(:)> [toleranceAbsolute]→, <double(:)> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorVectorized1D

<void> integrandSet(<<double(:)> function(doubleone x→)> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorVectorizedCompositeGaussKronrod1D

<double> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> evaluateInterval(<double> a→, <double> b→, <double> integralKronrod←, <double> error←) Evaluate the integral over an interval and also return the error on the integral.

<void> initialize(<integer> iterationsMaximum→, <integer> order→) Set the maximum number of iterations allowed, and the order of the integrator.

<void> integrandSet(<<double(:)> function(doubleone x→)> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

integratorVectorizedCompositeTrapezoidal1D

<double> evaluate(<double> a→, <double> b,→) Evaluate the integral.

<void> initialize(<integer> iterationsMaximum→) Set the maximum number of iterations allowed in the integrator.

<void> integrandSet(<<double(:)> function(doubleone x→)> integrand→) Set the integrand function to be integrated.

<void> toleranceSet(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set tolerances to use in this integrator.

intergalacticMediumFilteringMassClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((intergalacticMediumFilteringMassClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision massFiltering(\textcolor{red}{\textless double precision\textgreater}
time\argin) Return the filtering mass at the given time.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

intergalacticMediumFilteringMassGnedin2000

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double(:)> coefficientsEarlyEpoch(<double> time→) Return coefficients for the early-epoch fitting function to the filtering mass.

<void> conditionsInitialODEs(<double> time→, <double(:)> massFilteringODEs←, <double(:)> [massFilteringScales]←) Set the initial conditions for the ODE system.

void deepCopy(\textcolor{red}{\textless class((intergalacticMediumFilteringMassClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision massFiltering(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the filtering mass at the given time.

<double> massFilteringEarlyEpoch(<double> time→) Return the early-epoch solution for the filtering mass.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> tabulate(<double> time→) Tabulate the filtering mass to encompass at least the given time.

intergalacticMediumStateClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((intergalacticMediumStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision doublyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the doubly-ionized fraction of helium in the IGM at the given time.

`double precision electronFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the electron fraction (relative to hydrogen) in the IGM at the given time.

`double precision electronScatteringOpticalDepth(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the electron scattering optical depth from the present day back to the given `time` in the IGM.

`double precision electronScatteringTime(\textcolor{red}{\textless double precision\textgreater} opticalDepth\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the cosmological time at which the given electron scattering `opticalDepth` is reached (integrating from the present day) in the IGM.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massJeans(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the instantaneus Jeans mass (in $M_\odot$) at the given time.

`double precision neutralHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of helium in the IGM at the given time.

`double precision neutralHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of hydrogen in the IGM at the given time.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision singlyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of helium in the IGM at the given time.

double precision singlyIonizedHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the singly-ionized fraction of hydrogen in the IGM at the given time.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperature(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the temperature (in Kelvin) of the IGM at the given time.

intergalacticMediumStateFile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((intergalacticMediumStateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision doublyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the doubly-ionized fraction of helium in the IGM at the given time.

double precision electronFraction(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the electron fraction (relative to hydrogen) in the IGM at the given time.

double precision electronScatteringOpticalDepth(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin) Return the electron scattering optical depth from the present day back to the given time in the IGM.

double precision electronScatteringTime(\textcolor{red}{\textless double precision\textgreater} opticalDepth\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin) Return the cosmological time at which the given electron scattering opticalDepth is reached (integrating from the present day) in the IGM.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision massJeans(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the instantaneus Jeans mass (in $M_\odot$) at the given time.

double precision neutralHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin) Return the neutral fraction of helium in the IGM at the given time.

`double precision neutralHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of hydrogen in the IGM at the given time.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision singlyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of helium in the IGM at the given time.

`double precision singlyIonizedHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of hydrogen in the IGM at the given time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperature(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the temperature (in Kelvin) of the IGM at the given time.

intergalacticMediumStateInstantReionization

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((intergalacticMediumStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision doublyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the doubly-ionized fraction of helium in the IGM at the given time.

`double precision electronFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the electron fraction (relative to hydrogen) in the IGM at the given time.

`double precision electronScatteringOpticalDepth(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the electron scattering optical depth from the present day back to the given `time` in the IGM.

`double precision electronScatteringTime(\textcolor{red}{\textless double precision\textgreater} opticalDepth\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the cosmological time at which the given electron scattering `opticalDepth` is reached (integrating from the present day) in the IGM.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massJeans(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the instantaneus Jeans mass (in $M_\odot$) at the given time.

`double precision neutralHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of helium in the IGM at the given time.

`double precision neutralHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of hydrogen in the IGM at the given time.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision singlyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of helium in the IGM at the given time.

`double precision singlyIonizedHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of hydrogen in the IGM at the given time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperature(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the temperature (in Kelvin) of the IGM at the given time.

intergalacticMediumStateInternal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((intergalacticMediumStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision doublyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the doubly-ionized fraction of helium in the IGM at the given time.

`double precision electronFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the electron fraction (relative to hydrogen) in the IGM at the given time.

`double precision electronScatteringOpticalDepth(\textcolor{red}{\textless double precision\textgreater time\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the electron scattering optical depth from the present day back to the given `time` in the IGM.

`double precision electronScatteringTime(\textcolor{red}{\textless double precision\textgreater} opticalDepth\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the cosmological time at which the given electron scattering `opticalDepth` is reached (integrating from the present day) in the IGM.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massJeans(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the instantaneus Jeans mass (in $M_\odot$) at the given time.

`double precision neutralHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of helium in the IGM at the given time.

`double precision neutralHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of hydrogen in the IGM at the given time.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision singlyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of helium in the IGM at the given time.

`double precision singlyIonizedHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of hydrogen in the IGM at the given time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperature(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the temperature (in Kelvin) of the IGM at the given time.

intergalacticMediumStateRecFast

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((intergalacticMediumStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision doublyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the doubly-ionized fraction of helium in the IGM at the given time.

`double precision electronFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the electron fraction (relative to hydrogen) in the IGM at the given time.

`double precision electronScatteringOpticalDepth(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the electron scattering optical depth from the present day back to the given `time` in the IGM.

`double precision electronScatteringTime(\textcolor{red}{\textless double precision\textgreater} opticalDepth\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the cosmological time at which the given electron scattering `opticalDepth` is reached (integrating from the present day) in the IGM.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massJeans(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the instantaneus Jeans mass (in $M_\odot$) at the given time.

`double precision neutralHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of helium in the IGM at the given time.

`double precision neutralHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of hydrogen in the IGM at the given time.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision singlyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of helium in the IGM at the given time.

`double precision singlyIonizedHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of hydrogen in the IGM at the given time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperature(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the temperature (in Kelvin) of the IGM at the given time.

intergalacticMediumStateSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((intergalacticMediumStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision doublyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the doubly-ionized fraction of helium in the IGM at the given time.

`double precision electronFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the electron fraction (relative to hydrogen) in the IGM at the given time.

`double precision electronScatteringOpticalDepth(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the electron scattering optical depth from the present day back to the given `time` in the IGM.

`double precision electronScatteringTime(\textcolor{red}{\textless double precision\textgreater} opticalDepth\argin,\textcolor{red}{\textless logical\textgreater} assumeFullyIonized\argin)` Return the cosmological time at which the given electron scattering `opticalDepth` is reached (integrating from the present day) in the IGM.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin)` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massJeans(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the instantaneus Jeans mass (in $M_\odot$) at the given time.

`double precision neutralHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of helium in the IGM at the given time.

`double precision neutralHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the neutral fraction of hydrogen in the IGM at the given time.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision singlyIonizedHeliumFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of helium in the IGM at the given time.

`double precision singlyIonizedHydrogenFraction(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the singly-ionized fraction of hydrogen in the IGM at the given time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision temperature(\textcolor{red}{\textless double precision\textgreater} time\argin)` Return the temperature (in Kelvin) of the IGM at the given time.

irate

`<void> copyCosmology(<type(irate)> targetFile↔)` Copy "`Cosmology`" group from one IRATE file to another.

`<void> copySimulation(<type(irate)> targetFile↔)` Copy "`SimulationProperties`" group from one IRATE file to another.

`<void> readHalos(<integer> snapshot→, <double> [redshift]←, <double(:,:)> [center]←, <double(:,:)> [velocity]←, <double(:)> [mass]←)` Read a snapshot from the IRATE format file.

`<void> readSimulation(<double> [boxSize]←)` Read the request properties of the simulation from an IRATE format file.

`<void> writeHalos(<integer> snapshot→, <double> redshift→, <double(:,:)> [center]→, <double(:,:)> [velocity]→, <double(:)> [mass]→)` HASH(0x1efc330)

keplerOrbit

<double> angularMomentum() Returns the angular momentum of an orbit.

<void> angularMomentumSet(<double> angularMomentum→) Sets the angular momentum of an orbit.

<void> assertIsDefined() Asserts that an orbit is fully defined.

<void> builder(<*type(node)> keplerOrbitDefinition→) Build a Kepler orbit from an XML definition.

<void> destroy() Destroys an orbit.

<void> dump() Dump an orbit.

<void> dumpRaw(<integer> fileHandle→) Dump an orbit in binary.

<double> eccentricity() Returns the eccentricity of an orbit.

<void> eccentricitySet(<double> eccentricity→) Sets the eccentricity of an orbit.

<double> energy() Returns the energy of an orbit.

<void> energySet(<double> energy→) Sets the energy of an orbit.

<double> epsilon() Returns the angle ϵ of an orbit.

<void> epsilonSet(<double> theta→) Sets the angle ϵ of an orbit.

<double> hostMass() Returns the host mass of an orbit.

<logical> isBound() Returns true if the orbit is bound.

<logical> isDefined() Returns true if an orbit is fully defined.

<void> massesSet(<double> satelliteMass→, <double> hostMass→) Sets the masses of satellite and host objects.

<integer(c_size_t) > nonStaticSizeOf() Returns the size of any non-static components of the type.

<void> output(<integer> integerProperty↔, <integer> integerBufferCount↔, <integer(:,:)> integerBuffer↔, <integer>doubleProperty↔, <integer> doubleBufferCount↔, <double(:,:)> doubleBuffer↔, <double> time→, <integer> instance→) Store a keplerOrbit object in the output buffers.

<void> outputCount(<integer> integerPropertyCount↔, <integer> doublePropertyCount↔, <double> time→, <integer> instance→) Specify the count of a keplerOrbit object for output.

<void> outputNames(<integer> integerProperty↔, <char[*](:)> integerPropertyNames↔, <char[*](:)> integerPropertyComments↔, <double(:)> integerPropertyUnitsSI↔, <integer> doubleProperty↔, <char[*](:)> doublePropertyNames↔, <char[*](:)> doublePropertyComments↔, <double(:)> doublePropertyUnitsSI↔, <double> time→, <integer> instance→) Specify the names of a keplerOrbit object properties for output.

<double> phi() Returns the angle ϕ of an orbit.

<void> phiSet(<double> theta→) Sets the angle ϕ of an orbit.

<coordinateCartesian position() Returns the position coordinates.

<void> postOutput(<double> time→) Perform post-output processing of a keplerOrbit object.

<void> propagate(<double> velocityRadial→) Propagates an orbit to a new position.

<double> radius() Returns the radius of an orbit.

<double> radiusApocenter() Returns the apocenter radius of an orbit.

<void> radiusApocenterSet(<double> radius→) Sets the apocenter radius of an orbit.

<double> radiusPericenter() Returns the pericenter radius of an orbit.

<void> radiusPericenterSet(<double> radius→) Sets the pericenter radius of an orbit.

<void> radiusSet(<double> radius→) Sets the radius of an orbit.

<void> readRaw(<integer> fileHandle→) Read an orbit in binary.

<void> reset() Resets an orbit to a null state.

<double> semiMajorAxis() Returns the semi-major axis of an orbit.

<void> semiMajorAxisSet(<double> semiMajorAxis→) Sets the semi-major axis of an orbit.

<double> specificReducedMass() Returns the specific reduced mass (i.e. the reduced mass per unit satellite mass, $\mu_\mathrm{s} = M_\mathrm{host}/(M_\mathrm{satellite} + M_\mathrm{host})$) of the orbit.

<double> theta() Returns the angle θ of an orbit.

<void> thetaSet(<double> theta→) Sets the angle θ of an orbit.

<coordinateCartesian velocity() Returns the velocity coordinates.

<double> velocityRadial() Returns the radial velocity of an orbit.

<void> velocityRadialSet(<double> newRadius→) Sets the radial velocity of an orbit.

<double> velocityScale() Returns the velocity scale of an orbit.

<double> velocityTangential() Returns the tangential velocity of an orbit.

<void> velocityTangentialSet(<double> velocityTangential→) Sets the tangential velocity of an orbit.

linearGrowthClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((linearGrowthClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivativeExpansionFactor(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{r integer\textgreater} component \argin,\textcolor{red}{\textless double precision\textgreater} wavenumber \argin)` Return the logarithmic derivative of linear growth factor with respect to expansion factor.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless integer\textgreater} normalize\argin,\textcolor{red}{\t integer\textgreater} component \argin,\textcolor{red}{\textless double precision\textgreater} wavenumber \argin)` Return the linear growth factor at the given time and mass.

linearGrowthSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((linearGrowthClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivativeExpansionFactor(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{r integer\textgreater} component \argin,\textcolor{red}{\textless double precision\textgreater} wavenumber \argin)` Return the logarithmic derivative of linear growth factor with respect to expansion factor.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void retabulate(<double> time→)` Tabulate linear growth factor.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{re double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing \argin,\textcolor{red}{\textless integer\textgreater} normalize\argin,\textcolor{red}{\t integer\textgreater} component \argin,\textcolor{red}{\textless double precision\textgreater} wavenumber \argin)` Return the linear growth factor at the given time and mass.

localGroupDB

`<void> getProperty(<character(len=*)>name→, <type(varying_string)(:)>property↔)` Return an array of values of the named property for the current selection.

`<void> select(<character(len=*)>name→, <character(len=*)>value→)` Select all galaxies in the current selection where the named property has the given value.

`<void> selectAll()` Select all galaxies in the database.

`<void> update()` Update the database.

longIntegerHistory

<void> append((<double> time→, <integer(kind_int8)(:)> append→| <type(longIntegerHistory)> append→)) Append a history or single instant onto the end of a history.

<void> builder(<*type(node)> historyDefinition→) Build a history object from an XML definition.

<void> clone(<type(history)> historyToClone→) Clone a history object.

<void> create(<integer> historyCount→, <integer> timesCount→, <double> [timeBegin]→, <double> [timeEnd]→, <integer> [rangeType]→) Creates a history object with a specified range of times.

<void> destroy(<type(history)> historyToClone→) Destroys a history object.

<void> dump() Dump a history object.

<void> dumpRaw(<integer> fileHandle→) Dump a history object in binary.

<logical> exists() Returns true if the given history has been created.

<integer(c_size_t) > nonStaticSizeOf() Returns the size of any non-static components of the type.

<void> readRaw(<integer> fileHandle→) Read a history object in binary.

<void> reset() Resets all entries in a history to zero.

<void> trim(<double> currentTime→, <integer> [minimumPointsToRemove]→) Removes any times in a history which have become outdated.

<void> trimForward(<double> currentTime→, <type(longIntegerHistory)> [removedHistory]←) Removes any times in a history *after* the given time. Optionally returns a history object with the removed history.

massDistributionBetaProfile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the density of the distribution at the given coordinates.

double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin) Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isDimensionless()` Return true if the distribution is dimensionless.

`double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the mass enclosed in the distribution by a sphere of given radius.

`double precision massTotal()` Return the total mass of the distribution.

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin` Return the gravitational potential of the distribution at the given coordinates.

`<double> radiusHalfMass()` Returns the radius enclosing half of the mass of the mass distribution.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`integer symmetry()` Return the symmetry of the distribution.

massDistributionClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin)` Return the density of the distribution at the given coordinates.

`double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin)` Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

double precision massTotal() Return the total mass of the distribution.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the gravitational potential of the distribution at the given coordinates.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer symmetry() Return the symmetry of the distribution.

massDistributionCylindrical

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\textcolor{red}{\textless character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the density of the distribution at the given coordinates.

`double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin)` Return the radial gradient of density of the distribution at the given coordinates.

`double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout)` Return the radial moment of the distribution.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin)` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isDimensionless()` Return true if the distribution is dimensionless.

`double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin)` Return the mass enclosed in the distribution by a sphere of given radius.

`double precision massTotal()` Return the total mass of the distribution.

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin)` Return the gravitational potential of the distribution at the given coordinates.

`<double> radiusHalfMass()` Returns the cylindrical radius enclosing half of the mass of the mass distribution.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`<double> rotationCurve(<double> radius→)` Returns the circular velocity at the given `radius`.

`<double> rotationCurveGradient(<double> radius→)` Returns the gradient of the circular velocity at the given `radius`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<double> surfaceDensity(<class(coordinate)> coordinates→)` Returns the surface density at the given `coordinates`.

<double> surfaceDensityRadialMoment(<double> moment→, <double> radiusMinimum→, <double> radiusMaximum→, <logical> [isInfinite]←) Returns the $n^{\rm th}$ moment of the integral of the surface density over radius, $\int_0^\infty \Sigma(\mathbf{x})|x|^n \mathrm{d}\mathbf{x}$.

integer symmetry() Return the symmetry of the distribution.

massDistributionExponentialDisk

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<double> besselFactorPotential(<double> halfRadius→) Compute the Bessel function factor appearing in the exponential disk potential.

<double> besselFactorRotationCurve(<double> halfRadius→) Compute the Bessel function factor appearing in the exponential disk rotation curve.

<double> besselFactorRotationCurveGradient(<double> halfRadius→) Compute the Bessel function factor appearing in the exponential disk rotation curve gradient.

void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the density of the distribution at the given coordinates.

double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin) Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

double precision massTotal() Return the total mass of the distribution.

type(varying_string) objectType() Return the type of the object.

`double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin`
Return the gravitational potential of the distribution at the given coordinates.

`<double> radiusHalfMass()` Returns the cylindrical radius enclosing half of the mass of the mass distribution.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`<double> rotationCurve(<double> radius→)` Returns the circular velocity at the given `radius`.

`<double> rotationCurveGradient(<double> radius→)` Returns the gradient of the circular velocity at the given `radius`.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl`
`type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-`
`size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles`
`type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-`
`size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<double> surfaceDensity(<class(coordinate)> coordinates→)` Returns the surface density at the given `coordinates`.

`<double> surfaceDensityRadialMoment(<double> moment→, <double> radiusMinimum→, <double> radiusMaximum→, <logical> [isInfinite]←)` Returns the $n^{\rm th}$ moment of the integral of the surface density over radius, $\int_0^\infty \Sigma(\mathbf{x})|x|^n \mathrm{d}\mathbf{x}$.

`integer symmetry()` Return the symmetry of the distribution.

`<void> tabulate()` Tabulates the potential for an exponential disk mass distribution.

massDistributionHernquist

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\`
`character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou`
Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin)`
Return the density of the distribution at the given coordinates.

`double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater}`
`coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin)`
Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

double precision massTotal() Return the total mass of the distribution.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the gravitational potential of the distribution at the given coordinates.

<double> radiusHalfMass() Returns the radius enclosing half of the mass of the mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer symmetry() Return the symmetry of the distribution.

massDistributionMiyamotoNagai

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\textcolor{red}{\textless character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the density of the distribution at the given coordinates.

double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin) Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor{red}{\textless double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest) Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

<void> massEnclosedTabulate() Initialize the enclosed mass tabulation.

double precision massTotal() Return the total mass of the distribution.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the gravitational potential of the distribution at the given coordinates.

<double> radiusHalfMass() Returns the cylindrical radius enclosing half of the mass of the mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

<double> rotationCurve(<double> radius→) Returns the circular velocity at the given radius.

<double> rotationCurveGradient(<double> radius→) Returns the gradient of the circular velocity at the given radius.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> surfaceDensity(<class(coordinate)> coordinates→) Returns the surface density at the given coordinates.

<double> surfaceDensityRadialMoment(<double> moment→, <double> radiusMinimum→, <double> radiusMaximum→, <logical> [isInfinite]←) Returns the $n^{\rm th}$ moment of the integral of the surface density over radius, $\int_0^\infty \Sigma(\mathbf{x})|x|^n \mathrm{d}\mathbf{x}$.

<void> surfaceDensityTabulate() Initialize the surface density tabulation.

integer symmetry() Return the symmetry of the distribution.

massDistributionNFW

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the density of the distribution at the given coordinates.

double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin) Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

double precision massTotal() Return the total mass of the distribution.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin Return the gravitational potential of the distribution at the given coordinates.

<double> radiusHalfMass() Returns the radius enclosing half of the mass of the mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer symmetry() Return the symmetry of the distribution.

massDistributionSersic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou Perform a deep copy of the object.

double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin) Return the density of the distribution at the given coordinates.

double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin) Return the radial gradient of density of the distribution at the given coordinates.

double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout) Return the radial moment of the distribution.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

double precision massTotal() Return the total mass of the distribution.

`type(varying_string) objectType()` Return the type of the object.

`double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin` Return the gravitational potential of the distribution at the given coordinates.

`<double> radiusHalfMass()` Returns the radius enclosing half of the mass of the mass distribution.

`<double> radiusHalfMassProjected()` Return the half mass radius of the profile in projection.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`integer symmetry()` Return the symmetry of the distribution.

`<void> tabulate(<double> [radius]→)` Tabulate the Sersic profile.

massDistributionSpherical

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((massDistributionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`double precision density(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin)` Return the density of the distribution at the given coordinates.

`double precision densityGradientRadial(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin,\textcolor{red}{\textless logical\textgreater} logarithmic\argin)` Return the radial gradient of density of the distribution at the given coordinates.

`double precision densityRadialMoment(\textcolor{red}{\textless double precision\textgreater} moment\argin,\textcolor{red}{\textless double precision\textgreater} radiusMinimum\argin,\textcolor double precision\textgreater} radiusMaximum\argin,\textcolor{red}{\textless logical\textgreater} isInfinite\argout)` Return the radial moment of the distribution.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isDimensionless() Return true if the distribution is dimensionless.

double precision massEnclosedBySphere(\textcolor{red}{\textless double precision\textgreater} radius\argin) Return the mass enclosed in the distribution by a sphere of given radius.

double precision massTotal() Return the total mass of the distribution.

type(varying_string) objectType() Return the type of the object.

double precision potential(\textcolor{red}{\textless class((coordinate))\textgreater} coordinates\argin
Return the gravitational potential of the distribution at the given coordinates.

<double> radiusHalfMass() Returns the radius enclosing half of the mass of the mass distribution.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer symmetry() Return the symmetry of the distribution.

massFunctionIncompletenessClass
