
void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisPropertyOperatorNormal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((outputAnalysisPropertyOperatorClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision operate(\textcolor{red}{\textless double precision\textgreater} propertyValue\argin,\t type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} propertyType\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin)` Operate on the given property.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

outputAnalysisPropertyOperatorSequence

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((outputAnalysisPropertyOperatorClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} propertyValue\argin,\t
type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater}
propertyType\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin)
Operate on the given property.

<void> prepend(<class(outputAnalysisPropertyOperatorClass)> operator_→) Prepend an operator to a sequence of property operators.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisPropertyOperatorSquare

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisPropertyOperatorClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} propertyValue\argin,\t
type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater}
propertyType\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin)
Operate on the given property.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisPropertyOperatorSquareRoot

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisPropertyOperatorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} propertyValue\argin,\t type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} propertyType\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin) Operate on the given property.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisPropertyOperatorSystmtcPolynomial

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisPropertyOperatorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} propertyValue\argin,\t type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless integer\textgreater} propertyType\arginout,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin) Operate on the given property.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisScatterFunction1D

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void analyze(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex integer((c_size_t))\textgreater} iOutput\argin) Analyze the given node.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`void finalize()` Finalize the analysis.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logLikelihood()` Return the log-likelihood of the analysis.

`type(varying_string) objectType()` Return the type of the object.

`void reduce(\textcolor{red}{\textless class((outputAnalysisClass))\textgreater} reduced\arginout)` Reduce the object onto another object of the class.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

outputAnalysisSpinDistributionBett2007

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void analyze(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex integer((c_size_t))\textgreater} iOutput\argin)` Analyze the given `node`.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((outputAnalysisClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`void finalize()` Finalize the analysis.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logLikelihood() Return the log-likelihood of the analysis.

type(varying_string) objectType() Return the type of the object.

void reduce(\textcolor{red}{\textless class((outputAnalysisClass))\textgreater} reduced\arginout) Reduce the object onto another object of the class.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

<void> results(<double(:)> [binCenter]↔, <double(:,:)> [functionValue]↔, <double(:,:)> [functionCovariance]↔) Return the results of the volume function operator.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisStellarVsHaloMassRelationLeauthaud2012

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void analyze(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex integer((c_size_t))\textgreater} iOutput\argin) Analyze the given node.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

void finalize() Finalize the analysis.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logLikelihood() Return the log-likelihood of the analysis.

type(varying_string) objectType() Return the type of the object.

`void reduce(\textcolor{red}{\textless class((outputAnalysisClass))\textgreater} reduced\arginout)` Reduce the object onto another object of the class.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

outputAnalysisVolumeFunction1D

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

<double> rootVariance(<type(treeNode)> node↔, <double> propertyValue→, <double> propertyValueIntrinsi
<integer> propertyType→, <integer> propertyQuantity→, <integer(c_size_t)> outputIndex→)
Return the root-variance to use in the weight operator.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisWeightOperatorNormal

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisWeightOperatorClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} weightValue\argin,\tex
type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater}
propertyValue\argin,\textcolor{red}{\textless double precision\textgreater} propertyValueIntrinsic\
integer\textgreater} propertyType\argin,\textcolor{red}{\textless integer\textgreater}
propertyQuantity\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin
Operate on the given weight.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

<double> rootVariance(<type(treeNode)> node↔, <double> propertyValue→, <double> propertyValueIntrinsi
<integer> propertyType→, <integer> propertyQuantity→, <integer(c_size_t)> outputIndex→)
Return the root-variance to use in the weight operator.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisWeightOperatorProperty

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisWeightOperatorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} weightValue\argin,\tex type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater} propertyValue\argin,\textcolor{red}{\textless double precision\textgreater} propertyValueIntrinsic\ integer\textgreater} propertyType\argin,\textcolor{red}{\textless integer\textgreater} propertyQuantity\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin Operate on the given weight.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputAnalysisWeightOperatorSequence

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((outputAnalysisWeightOperatorClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision operate(\textcolor{red}{\textless double precision\textgreater} weightValue\argin,\tex
type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless double precision\textgreater}
propertyValue\argin,\textcolor{red}{\textless double precision\textgreater} propertyValueIntrinsic\
integer\textgreater} propertyType\argin,\textcolor{red}{\textless integer\textgreater}
propertyQuantity\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} outputIndex\argin
Operate on the given weight.

<void> prepend(<class(outputAnalysisWeightOperatorClass)> operator_→) Prepend an operator to a sequence of weight operators.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

outputTimesClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

integer(c_size_t) count() Return the number of output times.

`void deepCopy(\textcolor{red}{\textless class((outputTimesClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`integer(c_size_t) index(\textcolor{red}{\textless double precision\textgreater} time \argin,\textcolor{ logical\textgreater} findClosest\argin)` Return the index of the output at the given `time`. If `findClosest` is given and is true then the closest matching output is returned.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision redshift(\textcolor{red}{\textless integer((c_size_t))\textgreater} indexOutput\argin)` Return the output redshift index by `indexOutput`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision time(\textcolor{red}{\textless integer((c_size_t))\textgreater} indexOutput\argin)` Return the output time index by `indexOutput`.

`double precision timeNext(\textcolor{red}{\textless double precision\textgreater} timeCurrent\argin,\te integer((c_size_t))\textgreater} indexOutput\argout)` Given a `time`, return the time of the next output, and (optionally) the index of that output.

`double precision timePrevious(\textcolor{red}{\textless double precision\textgreater} timeCurrent\argin` Given a `time`, return the time of the previous output.

outputTimesList

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`integer(c_size_t) count()` Return the number of output times.

`void deepCopy(\textcolor{red}{\textless class((outputTimesClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`integer(c_size_t) index(\textcolor{red}{\textless double precision\textgreater} time \argin,\textcolor{ logical\textgreater} findClosest\argin)` Return the index of the output at the given `time`. If `findClosest` is given and is true then the closest matching output is returned.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision redshift(\textcolor{red}{\textless integer((c_size_t))\textgreater} indexOutput\argin)` Return the output redshift index by `indexOutput`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision time(\textcolor{red}{\textless integer((c_size_t))\textgreater} indexOutput\argin)` Return the output time index by `indexOutput`.

`double precision timeNext(\textcolor{red}{\textless double precision\textgreater} timeCurrent\argin,\te integer((c_size_t))\textgreater} indexOutput\argout)` Given a `time`, return the time of the next output, and (optionally) the index of that output.

`double precision timePrevious(\textcolor{red}{\textless double precision\textgreater} timeCurrent\argin` Given a `time`, return the time of the previous output.

polygon

`<logical> pointIncluded(<double(3)> point→)` Return true if the given point lives inside the MANGLE polygon.

polynomialIterator

<integer(:)> counter() Return an incremental counter (i.e. begins at 0 and increases by 1 on each iteration).

<integer(:)> currentOrder() Return the current order of the polynomial coefficient.

<integer(:)> index(<integer(:)> i→) Return the i^{th} index of the polynomial coefficient.

<logical> iterate() Move to the next iteration of polynomial coefficient indices. Returns true if successful. If no more iterations are available, returns false.

<void> reset() Reset the iterator object to the start of its sequence.

posteriorSampleConvergenceClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

integer convergedAtStep() Returns the step at which the sampling reached convergence.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

logical isConverged(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihood\argi Returns true if the posterior sampling is deemed to be converged.

<logical> isDefault() Return true if this is the default object of this class.

void logReport(\textcolor{red}{\textless integer\textgreater} fileUnit\argin) Log a report on convergence state to the given file unit.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void reset() Reset the convergence calculation.

logical stateIsOutlier(\textcolor{red}{\textless integer\textgreater} stateIndex\argin) Return true if the specified state is deemed to be an outlier.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleConvergenceGelmanRubin

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`integer convergedAtStep()` Returns the step at which the sampling reached convergence.

`<double> convergenceMeasure()` Return the current convergence measure, $\hat{R}$.

`<double> convergenceMeasureTarget()` Return the target convergence measure, $\hat{R}$.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isConverged(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihood\argi` Returns true if the posterior sampling is deemed to be converged.

`<logical> isDefault()` Return true if this is the default object of this class.

`void logReport(\textcolor{red}{\textless integer\textgreater} fileUnit\argin)` Log a report on convergence state to the given file unit.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void reset()` Reset the convergence calculation.

`logical stateIsOutlier(\textcolor{red}{\textless integer\textgreater} stateIndex\argin)` Return true if the specified state is deemed to be an outlier.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleConvergenceLikelihoodThreshold

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`integer convergedAtStep()` Returns the step at which the sampling reached convergence.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isConverged(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihood\argi` Returns true if the posterior sampling is deemed to be converged.

`<logical> isDefault()` Return true if this is the default object of this class.

`void logReport(\textcolor{red}{\textless integer\textgreater} fileUnit\argin)` Log a report on convergence state to the given file unit.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void reset()` Reset the convergence calculation.

`logical stateIsOutlier(\textcolor{red}{\textless integer\textgreater} stateIndex\argin)` Return true if the specified state is deemed to be an outlier.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleConvergenceNever

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`integer convergedAtStep()` Returns the step at which the sampling reached convergence.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isConverged(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihood\argi` Returns true if the posterior sampling is deemed to be converged.

`<logical> isDefault()` Return true if this is the default object of this class.

`void logReport(\textcolor{red}{\textless integer\textgreater} fileUnit\argin)` Log a report on convergence state to the given file unit.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void reset()` Reset the convergence calculation.

`logical stateIsOutlier(\textcolor{red}{\textless integer\textgreater} stateIndex\argin)` Return true if the specified state is deemed to be an outlier.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleDffrntlEvltnProposalSizeAdaptive

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnProposalSizeClass))\textgreat destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision gamma(\textcolor{red}{\textless class((posteriorSampleStateClass ))\textgreater} simulationState\arginout,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgre simulationConvergence\arginout)` Sample from the jump distribution.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleDffrntlEvltnProposalSizeClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnProposalSizeClass))\textgreat destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

double precision gamma(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgre simulationConvergence\arginout) Sample from the jump distribution.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleDffrntlEvltnProposalSizeFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnProposalSizeClass))\textgreat destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision gamma(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgre simulationConvergence\arginout) Sample from the jump distribution.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleDffrntlEvltnPrpslSzTmpExpAdaptive

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnPrpslSzTmpExpClass))\textgrea destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision exponent(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} temperedStates\arginout,\textcolor{red}{\textless double precision\textgreater} temperatures\argin, class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreater} simulationConvergence\arginout) Return the temperature exponent.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleDffrntlEvltnPrpslSzTmpExpClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnPrpslSzTmpExpClass))\textgrea
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision exponent(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater}
temperedStates\arginout,\textcolor{red}{\textless double precision\textgreater} temperatures\argin,
class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless
class((posteriorSampleConvergenceClass))\textgreater} simulationConvergence\arginout)
Return the temperature exponent.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleDffrntlEvltnPrpslSzTmpExpFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnPrpslSzTmpExpClass))\textgrea
destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision exponent(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} temperedStates\arginout,\textcolor{red}{\textless double precision\textgreater} temperatures\argin, class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreater} simulationConvergence\arginout)` Return the temperature exponent.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleDffrntlEvltnRandomJumpAdaptive

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnRandomJumpClass))\textgreater destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision, dimension(size(modelParameters_)) sample(\textcolor{red}{\textless type((modelParamet
))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleStateClass))
simulationState\arginout) Sample from the jump distribution.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleDffrntlEvltnRandomJumpClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnRandomJumpClass))\textgreater
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision, dimension(size(modelParameters_)) sample(\textcolor{red}{\textless type((modelParamet
))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleStateClass))
simulationState\arginout) Sample from the jump distribution.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleDffrntlEvltnRandomJumpSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleDffrntlEvltnRandomJumpClass))\textgreater destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision, dimension(size(modelParameters_)) sample(\textcolor{red}{\textless type((modelParamet ))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleStateClass)) simulationState\arginout)` Sample from the jump distribution.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleLikelihoodClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

void functionChanged() Respond to possible changes in the likelihood function.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r double precision\textgreater} logLikelihood\argin) Log a report on convergence state to the given file unit.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodGalaxyPopulation

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi
double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double
precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodMassFunction

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater}
simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater}
modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater}
modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t

simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

void functionChanged() Respond to possible changes in the likelihood function.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r double precision\textgreater} logLikelihood\argin) Log a report on convergence state to the given file unit.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodMltiVrtNormalStochastic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

void functionChanged() Respond to possible changes in the likelihood function.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r double precision\textgreater} logLikelihood\argin) Log a report on convergence state to the given file unit.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodMultivariateNormal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout)` Evaluate the likelihood.

`void functionChanged()` Respond to possible changes in the likelihood function.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r double precision\textgreater} logLikelihood\argin)` Log a report on convergence state to the given file unit.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodPosteriorAsPrior

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

void functionChanged() Respond to possible changes in the likelihood function.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> initialize(<type(mappingList)[:]> modelParametersActive_→) Initialize the posterior-as-prior likelihood.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r
double precision\textgreater} logLikelihood\argin) Log a report on convergence state to the given file unit.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater}
simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater}
modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat

precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater}
timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance
logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

void functionChanged() Respond to possible changes in the likelihood function.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r double precision\textgreater} logLikelihood\argin) Log a report on convergence state to the given file unit.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodSEDFit

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

`void functionChanged()` Respond to possible changes in the likelihood function.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r` `double precision\textgreater} logLikelihood\argin)` Log a report on convergence state to the given file unit.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl` `type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-` `size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles` `type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-` `size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass ))\textgreater}` `simulationState\arginout,\textcolor{red}{\textless type((modelParameterList ))\textgreater}` `modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat` `simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater}` `temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi` `double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double` `precision\textgreater} logPriorProposed\argin)` Returns true if the likelihood will be evaluated for this state.

posteriorSampleLikelihoodSpinDistribution

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\` `character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater}` `destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex` `logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

double precision evaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersActive_\argin,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParametersInactive_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\t simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin,\textcolor{red}{\textless real\textgreater} timeEvaluate\arginout,\textcolor{red}{\textless double precision\textgreater} logLikelihoodVariance logical\textgreater} forceAcceptance\arginout) Evaluate the likelihood.

void functionChanged() Respond to possible changes in the likelihood function.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void restore(\textcolor{red}{\textless double precision\textgreater} simulationState\argin,\textcolor{r double precision\textgreater} logLikelihood\argin) Log a report on convergence state to the given file unit.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical willEvaluate(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleConvergenceClass))\textgreat simulationConvergence\arginout,\textcolor{red}{\textless double precision\textgreater} temperature\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihoodCurrent\argi double precision\textgreater} logPriorCurrent\argin,\textcolor{red}{\textless double precision\textgreater} logPriorProposed\argin) Returns true if the likelihood will be evaluated for this state.

posteriorSampleSimulationAnnealedDffrntlEvltn

<logical> acceptProposal(<double> logPosterior→, <double> logPosteriorProposed→, <type(pseudoRandom)> randomNumberGenerator↔) Return true if the proposed state should be accepted.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<integer> chainSelect(<type(pseudoRandom)> randomNumberGenertor↔, <integer(:)> [blockedChains]→) Select a chain.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleSimulationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> initialize(<integer> temperatureLevelCount→, <double> temperatureMaximum) Initialize the object.

<logical> isDefault() Return true if this is the default object of this class.

<integer> level() Return the current tempering level.

<logical> logging() Return true if the simulator is currently logging state.

type(varying_string) objectType() Return the type of the object.

<double> posterior(<class(posteriorSampleStateClass)> posteriorSampleState_→) Return the log of posterior probability for the given posteriorSampleState.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void simulate() Perform the simulation.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> stepSize() Return the step size parameter, γ, for the differential evolution proposal vector.

<double> temperature() Return the current temperature.

<void> update(<double(:)> stateVector→) Update the simulator to the new stateVector after a step.

posteriorSampleSimulationClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleSimulationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void simulate() Perform the simulation.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleSimulationDifferentialEvolution

<logical> acceptProposal(<double> logPosterior→, <double> logPosteriorProposed→, <type(pseudoRandom)> randomNumberGenerator↔) Return true if the proposed state should be accepted.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<integer> chainSelect(<type(pseudoRandom)> randomNumberGenertor↔, <integer(:)> [blockedChains]→) Select a chain.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleSimulationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`<logical> logging()` Return true if the simulator is currently logging state.

`type(varying_string) objectType()` Return the type of the object.

`<double> posterior(<class(posteriorSampleStateClass)> posteriorSampleState_→)` Return the log of posterior probability for the given `posteriorSampleState`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void simulate()` Perform the simulation.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<double> stepSize()` Return the step size parameter, γ, for the differential evolution proposal vector.

`<double> temperature()` Return the current temperature.

`<void> update(<double(:)> stateVector→)` Update the simulator to the new `stateVector` after a step.

posteriorSampleSimulationParticleSwarm

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleSimulationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<double> posterior(<class(posteriorSampleStateClass)> simulationState→) Return the log of posterior probability for the given simulationState.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void simulate() Perform the simulation.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleSimulationStochasticDffrntlEvltn

<logical> acceptProposal(<double> logPosterior→, <double> logPosteriorProposed→, <type(pseudoRandom)> randomNumberGenerator↔) Return true if the proposed state should be accepted.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<integer> chainSelect(<type(pseudoRandom)> randomNumberGenertor↔, <integer(:)> [blockedChains]→) Select a chain.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleSimulationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> initialize(<integer> temperatureLevelCount→, <double> temperatureMaximum) Initialize the object.

<logical> isDefault() Return true if this is the default object of this class.

<logical> logging() Return true if the simulator is currently logging state.

type(varying_string) objectType() Return the type of the object.

<double> posterior(<class(posteriorSampleStateClass)> posteriorSampleState_→) Return the log of posterior probability for the given posteriorSampleState.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void simulate() Perform the simulation.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> stepSize() Return the step size parameter, γ, for the differential evolution proposal vector.

<double> temperature() Return the current temperature.

<void> update(<double(:)> stateVector→) Update the simulator to the new stateVector after a step.

posteriorSampleSimulationTemperedDffrntlEvltn

<logical> acceptProposal(<double> logPosterior→, <double> logPosteriorProposed→, <type(pseudoRandom)> randomNumberGenerator↔) Return true if the proposed state should be accepted.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<integer> chainSelect(<type(pseudoRandom)> randomNumberGenertor↔, <integer(:)> [blockedChains]→) Select a chain.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleSimulationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> initialize(<class(posteriorSampleDffrntlEvltnPrpslSzTmpExpClass)> posteriorSampleDffrntlEvltnPrp →) Return the current tempering level.

<logical> isDefault() Return true if this is the default object of this class.

<integer> level() Return the current tempering level.

<logical> logging() Return true if the simulator is currently logging state.

type(varying_string) objectType() Return the type of the object.

<double> posterior(<class(posteriorSampleStateClass)> posteriorSampleState_→) Return the log of posterior probability for the given posteriorSampleState.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void simulate() Perform the simulation.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> stepSize() Return the step size parameter, γ, for the differential evolution proposal vector.

<double> temperature() Return the current temperature.

<void> update(<double(:)> stateVector→) Update the simulator to the new stateVector after a step.

posteriorSampleStateClass

double precision acceptanceRate() Return the state acceptance rate.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

integer chainIndex() Return the index of the chain associated with this state.

void chainIndexSet(\textcolor{red}{\textless integer\textgreater} chainIndex\argin) Set the index of the chain associated with this state.

integer count() Returns the number of steps in the current state.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

`integer dimension()` Returns the dimension of the state.

`double precision, dimension(self%parameterCount) get()` Get the current state vector.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision, dimension(self%parameterCount) mean()` Return the mean state.

`type(varying_string) objectType()` Return the type of the object.

`void parameterCountSet(\textcolor{red}{\textless integer\textgreater} parameterCount\argin)` Set the number of parameters in this state.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void reset()` Reset the state object.

`void restore(\textcolor{red}{\textless double precision\textgreater} stateVector\argin,\textcolor{red}{` `logical\textgreater} first\argin)` Restore the state, one step at a time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl` `type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-` `size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles` `type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-` `size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void update(\textcolor{red}{\textless double precision\textgreater} stateNew\argin,\textcolor{red}{\tex` `logical\textgreater} logState\argin,\textcolor{red}{\textless logical\textgreater}` `isConverged\argin,\textcolor{red}{\textless logical\textgreater} outlierMask\argin)` Update the state vector.

`double precision, dimension(self%parameterCount) variance()` Return the variance in the state vector.

posteriorSampleStateCorrelation

`double precision acceptanceRate()` Return the state acceptance rate.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\` `character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`integer chainIndex()` Return the index of the chain associated with this state.

`void chainIndexSet(\textcolor{red}{\textless integer\textgreater} chainIndex\argin)` Set the index of the chain associated with this state.

`<integer> correlationLength()` Return the current correlation length in the chains.

`<integer> correlationLengthCompute(<logical(:)> [outlierMask]→)` Compute correlation lengths in the chains.

`integer count()` Returns the number of steps in the current state.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`integer dimension()` Returns the dimension of the state.

`double precision, dimension(self%parameterCount) get()` Get the current state vector.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision, dimension(self%parameterCount) mean()` Return the mean state.

`type(varying_string) objectType()` Return the type of the object.

`void parameterCountSet(\textcolor{red}{\textless integer\textgreater} parameterCount\argin)` Set the number of parameters in this state.

`<integer> postConvergenceCorrelationCount()` Return the number of post-convergence correlation lengths that have accrued.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void reset()` Reset the state object.

`void restore(\textcolor{red}{\textless double precision\textgreater} stateVector\argin,\textcolor{red}{ logical\textgreater} first\argin)` Restore the state, one step at a time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void update(\textcolor{red}{\textless double precision\textgreater} stateNew\argin,\textcolor{red}{\tex logical\textgreater} logState\argin,\textcolor{red}{\textless logical\textgreater} isConverged\argin,\textcolor{red}{\textless logical\textgreater} outlierMask\argin)` Update the state vector.

`double precision, dimension(self%parameterCount) variance()` Return the variance in the state vector.

posteriorSampleStateHistory

`double precision acceptanceRate()` Return the state acceptance rate.

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`integer chainIndex()` Return the index of the chain associated with this state.

`void chainIndexSet(\textcolor{red}{\textless integer\textgreater} chainIndex\argin)` Set the index of the chain associated with this state.

`integer count()` Returns the number of steps in the current state.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`integer dimension()` Returns the dimension of the state.

`double precision, dimension(self%parameterCount) get()` Get the current state vector.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision, dimension(self%parameterCount) mean()` Return the mean state.

`type(varying_string) objectType()` Return the type of the object.

`void parameterCountSet(\textcolor{red}{\textless integer\textgreater} parameterCount\argin)` Set the number of parameters in this state.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void reset()` Reset the state object.

`void restore(\textcolor{red}{\textless double precision\textgreater} stateVector\argin,\textcolor{red}{\textless logical\textgreater} first\argin)` Restore the state, one step at a time.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void update(\textcolor{red}{\textless double precision\textgreater} stateNew\argin,\textcolor{red}{\textless logical\textgreater} logState\argin,\textcolor{red}{\textless logical\textgreater} isConverged\argin,\textcolor{red}{\textless logical\textgreater} outlierMask\argin)` Update the state vector.

`double precision, dimension(self%parameterCount) variance()` Return the variance in the state vector.

posteriorSampleStateInitializeClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\textcolor{red}{\textless character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateInitializeClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin)` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`void initialize(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreater} modelLikelihood\arginout,\textcolor{red}{\textless double precision\textgreater} timeEvaluatePrevious\argin,\textcolor{red}{\textless double precision\textgreater} logLikelihood\argout,\textcolor{red}{\textless double precision\textgreater} logPosterior\argout)` Initialize the state of the posterior sampler.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleStateInitializeLatinHypercube

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateInitializeClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`void initialize(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreate modelLikelihood\arginout,\textcolor{red}{\textless double precision\textgreater} timeEvaluatePrevio double precision\textgreater} logLikelihood\argout,\textcolor{red}{\textless double precision\textgreater} logPosterior\argout)` Initialize the state of the posterior sampler.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleStateInitializePriorRandom

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateInitializeClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

void initialize(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater}
simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater}
modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreate
modelLikelihood\arginout,\textcolor{red}{\textless double precision\textgreater} timeEvaluatePrevio
double precision\textgreater} logLikelihood\argout,\textcolor{red}{\textless double
precision\textgreater} logPosterior\argout) Initialize the state of the posterior sampler.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleStateInitializeResume

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateInitializeClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`void initialize(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreate modelLikelihood\arginout,\textcolor{red}{\textless double precision\textgreater} timeEvaluatePrevio double precision\textgreater} logLikelihood\argout,\textcolor{red}{\textless double precision\textgreater} logPosterior\argout)` Initialize the state of the posterior sampler.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

posteriorSampleStateInitializeSwitched

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateInitializeClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`void initialize(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout,\textcolor{red}{\textless type((modelParameterList))\textgreater} modelParameters_\argin,\textcolor{red}{\textless class((posteriorSampleLikelihoodClass))\textgreate modelLikelihood\arginout,\textcolor{red}{\textless double precision\textgreater} timeEvaluatePrevio`

double precision\textgreater} logLikelihood\argout,\textcolor{red}{\textless double precision\textgreater} logPosterior\argout) Initialize the state of the posterior sampler.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

posteriorSampleStateSimple

double precision acceptanceRate() Return the state acceptance rate.

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

integer chainIndex() Return the index of the chain associated with this state.

void chainIndexSet(\textcolor{red}{\textless integer\textgreater} chainIndex\argin) Set the index of the chain associated with this state.

integer count() Returns the number of steps in the current state.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

integer dimension() Returns the dimension of the state.

double precision, dimension(self%parameterCount) get() Get the current state vector.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision, dimension(self%parameterCount) mean() Return the mean state.

type(varying_string) objectType() Return the type of the object.

void parameterCountSet(\textcolor{red}{\textless integer\textgreater} parameterCount\argin) Set the number of parameters in this state.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void reset() Reset the state object.

void restore(\textcolor{red}{\textless double precision\textgreater} stateVector\argin,\textcolor{red}{\ logical\textgreater} first\argin) Restore the state, one step at a time.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

void update(\textcolor{red}{\textless double precision\textgreater} stateNew\argin,\textcolor{red}{\tex logical\textgreater} logState\argin,\textcolor{red}{\textless logical\textgreater} isConverged\argin,\textcolor{red}{\textless logical\textgreater} outlierMask\argin) Update the state vector.

double precision, dimension(self%parameterCount) variance() Return the variance in the state vector.

posteriorSampleStoppingCriterionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleStoppingCriterionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical stop(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout) Returns true if the posterior sampling should stop.

posteriorSampleStoppingCriterionCorrelationLength

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((posteriorSampleStoppingCriterionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical stop(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout) Returns true if the posterior sampling should stop.

posteriorSampleStoppingCriterionNever

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStoppingCriterionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`logical stop(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater} simulationState\arginout)` Returns true if the posterior sampling should stop.

posteriorSampleStoppingCriterionStepCount

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((posteriorSampleStoppingCriterionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical stop(\textcolor{red}{\textless class((posteriorSampleStateClass))\textgreater}
simulationState\arginout) Returns true if the posterior sampling should stop.

powerSpectrumClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((powerSpectrumClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision power(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)
Return the linear power spectrum for $k =$wavenumber [Mpc^{-1}].

double precision powerDimensionless(\textcolor{red}{\textless double precision\textgreater}
wavenumber\argin) Return the dimensionless linear power spectrum for $k =$wavenumber [Mpc^{-1}].

double precision powerLogarithmicDerivative(\textcolor{red}{\textless double precision\textgreater}
wavenumber\argin) Return the logarithmic derivative of the power spectrum, $\mathrm{d}\ln P(k)/\mathrm{d}\ln k$, for $k =$wavenumber [Mpc^{-1}].

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

powerSpectrumNonlinearClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((powerSpectrumNonlinearClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} time\argin) Return the nonlinear power spectrum for $k =$wavenumber [Mpc^{-1}] at cosmic time $t =$time [Gyr].

powerSpectrumNonlinearCosmicEmu

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumNonlinearClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} time\argin)` Return the nonlinear power spectrum for $k =$`wavenumber` [Mpc^{-1}] at cosmic time $t =$`time` [Gyr].

powerSpectrumNonlinearLinear

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumNonlinearClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco
double precision\textgreater} time\argin) Return the nonlinear power spectrum for $k =$wavenumber [Mpc^{-1}] at cosmic time $t =$time [Gyr].

powerSpectrumNonlinearPeacockDodds1996

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((powerSpectrumNonlinearClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} time\argin) Return the nonlinear power spectrum for $k =$wavenumber [Mpc^{-1}] at cosmic time $t =$time [Gyr].

powerSpectrumPrimordialClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((powerSpectrumPrimordialClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative with respect to wavenumber of the primordial power spectrum at the given wavenumber (specified in units of Mpc^{-1}.

type(varying_string) objectType() Return the type of the object.

double precision power(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the (unnormalized) power in the primordial power spectrum at the given wavenumber (specified in units of Mpc^{-1}.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

powerSpectrumPrimordialPowerLaw

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumPrimordialClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative with respect to wavenumber of the primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}.

`type(varying_string) objectType()` Return the type of the object.

`double precision power(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the (unnormalized) power in the primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

powerSpectrumPrimordialTransferredClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumPrimordialTransferredClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative with respect to wavenumber of the transferred primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}.

`type(varying_string) objectType()` Return the type of the object.

`double precision power(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the (unnormalized) power in the transferred primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

powerSpectrumPrimordialTransferredSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumPrimordialTransferredClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative with respect to wavenumber of the transferred primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}.

`type(varying_string) objectType()` Return the type of the object.

`double precision power(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the (unnormalized) power in the transferred primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

powerSpectrumStandard

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision power(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the linear power spectrum for $k =$`wavenumber` $[\mathrm{Mpc}^{-1}]$.

`double precision powerDimensionless(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the dimensionless linear power spectrum for $k =$`wavenumber` $[\mathrm{Mpc}^{-1}]$.

`double precision powerLogarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative of the power spectrum, $\mathrm{d}\ln P(k)/\mathrm{d}\ln k$, for $k =$`wavenumber` $[\mathrm{Mpc}^{-1}]$.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

powerSpectrumWindowFunctionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

logical amplitudeIsMassIndependent() Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((powerSpectrumWindowFunctionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} smoothingMass\argin)` Returns the window function for power spectrum variance computation at the specified `wavenumber` (in Mpc^{-1}) for a given `smoothingMass` (in $M_\odot$).

`double precision wavenumberMaximum(\textcolor{red}{\textless double precision\textgreater} smoothingMass\argin)` Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given `smoothingMass` (in $M_\odot$).

powerSpectrumWindowFunctionLagrangianChan2017

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`logical amplitudeIsMassIndependent()` Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumWindowFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} smoothingMass\argin)` Returns the window function for power spectrum variance computation at the specified `wavenumber` (in Mpc^{-1}) for a given `smoothingMass` (in $M_\odot$).

`double precision wavenumberMaximum(\textcolor{red}{\textless double precision\textgreater} smoothingMass\argin)` Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given `smoothingMass` (in $M_\odot$).

powerSpectrumWindowFunctionSharpKSpace

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

logical amplitudeIsMassIndependent() Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((powerSpectrumWindowFunctionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco
double precision\textgreater} smoothingMass\argin) Returns the window function for power spectrum variance computation at the specified wavenumber (in Mpc^{-1}) for a given smoothingMass (in $M_\odot$).

double precision wavenumberMaximum(\textcolor{red}{\textless double precision\textgreater} smoothingMass\argin) Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given smoothingMass (in $M_\odot$).

powerSpectrumWindowFunctionSmoothKSpace

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

`logical amplitudeIsMassIndependent()` Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumWindowFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} smoothingMass\argin)` Returns the window function for power spectrum variance computation at the specified `wavenumber` (in Mpc^{-1}) for a given `smoothingMass` (in $M_\odot$).

`double precision wavenumberMaximum(\textcolor{red}{\textless double precision\textgreater} smoothingMass\argin)` Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given `smoothingMass` (in $M_\odot$).

powerSpectrumWindowFunctionTopHat

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`logical amplitudeIsMassIndependent()` Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumWindowFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} smoothingMass\argin)` Returns the window function for power spectrum variance computation at the specified `wavenumber` (in Mpc^{-1}) for a given `smoothingMass` (in $M_\odot$).

`double precision wavenumberMaximum(\textcolor{red}{\textless double precision\textgreater} smoothingMass\argin)` Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given `smoothingMass` (in $M_\odot$).

powerSpectrumWindowFunctionTopHatSharpKHybrid

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`logical amplitudeIsMassIndependent()` Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((powerSpectrumWindowFunctionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<void> radii(<double> smoothingMass→,<double> radiusTopHat→,<double> radiusKSpaceSharp→) Set the radii of the components of the window function.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin,\textco double precision\textgreater} smoothingMass\argin) Returns the window function for power spectrum variance computation at the specified wavenumber (in Mpc^{-1}) for a given smoothingMass (in $M_\odot$).

double precision wavenumberMaximum(\textcolor{red}{\textless double precision\textgreater} smoothingMass\argin) Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given smoothingMass (in $M_\odot$).

progenitorIterator

<*class(nodeData)> current(<class(nodeData)(:)> nodes→) Return a pointer to the current progenitor.

<void> descendentSet(<class(nodeData)> node→, <class(nodeData)(:)> nodes→) Set the target descendent node and initialize the iterator.

<logical> exist() Return true if any progenitors exist, false otherwise.

<integer(kind=kind_int8)> index(<class(nodeData)(:)> nodes→) Return the index of the current progenitor.

<logical> next(<class(nodeData)(:)> nodes→) Move to the next progenitor. Returns true if the next progenitor exists, false otherwise.

pseudoRandom

<type(pseudoRandom)> clone() Clone a pseudo-random number generator.

<double> normalSample(<double> mean) Return a pseudo-random number drawn from a standard normal distribution.

<integer> poissonSample(<double> mean) Return a pseudo-random number drawn from a Poisson distribution of the given mean.

<void> restore(<integer> stateFile→, <type(fgsl_file)> fgslStateFile→) Restore a pseudo-random number generator state from file.

<void> store(<integer> stateFile→, <type(fgsl_file)> fgslStateFile→) Store a pseudo-random number generator state to file.

<double> uniformSample() Return a pseudo-random number drawn from a uniform distribution on the interval 0 to 1.

radiationFieldBlackBody

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout) Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout) Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in wavelengthRange over a cross section specified by the function crossSectionFunction.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> temperature() Return the temperature of te black-body radiation field.

radiationFieldClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout)` Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout)` Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in `wavelengthRange` over a cross section specified by the function `crossSectionFunction`.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

radiationFieldCosmicMicrowaveBackground

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout)` Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout)` Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in `wavelengthRange` over a cross section specified by the function `crossSectionFunction`.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<double> temperature()` Return the temperature of te black-body radiation field.

`<void> timeSet(<double> time→)` Set the time for the radiation field.

radiationFieldIntergalacticBackground

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout)` Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout)` Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in `wavelengthRange` over a cross section specified by the function `crossSectionFunction`.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<void> timeSet(<double> time→)` Set the time for the radiation field.

radiationFieldIntergalacticBackgroundFile

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout)` Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges`
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout)` Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in `wavelengthRange` over a cross section specified by the function `crossSectionFunction`.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<void> timeSet(<double> time→)` Set the time for the radiation field.

radiationFieldIntergalacticBackgroundInternal

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout)` Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges`
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout)` Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in `wavelengthRange` over a cross section specified by the function `crossSectionFunction`.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> timeSet(<double> time→) Set the time for the radiation field.

radiationFieldNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout) Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout) Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in wavelengthRange over a cross section specified by the function crossSectionFunction.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

radiationFieldSummation

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((radiationFieldClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision flux(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcol type((treeNode))\textgreater} node\arginout) Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrateOverCrossSection(\textcolor{red}{\textless double precision\textgreater} wavelengthRange\argin,\textcolor{red}{\textless double precision\textgreater} crossSectionFunction, type((treeNode))\textgreater} node\arginout) Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in wavelengthRange over a cross section specified by the function crossSectionFunction.

<logical> isDefault() Return true if this is the default object of this class.

<void> list(<*type(radiationFieldList)>) Return a list of all sub-components.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

ramPressureStrippingDisksClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((ramPressureStrippingDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the disk component of `node`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

ramPressureStrippingDisksNull

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((ramPressureStrippingDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the disk component of `node`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

ramPressureStrippingDisksSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((ramPressureStrippingDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the disk component of `node`.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

ramPressureStrippingSpheroidsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((ramPressureStrippingSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the spheroid component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

ramPressureStrippingSpheroidsNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((ramPressureStrippingSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the spheroid component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

ramPressureStrippingSpheroidsSimple

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((ramPressureStrippingSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the spheroid component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

regEx

<void> destroy() Destroy the regex.

<logical> matches(<character(len=*)> string→) Return true if a regular expression matches the supplied string.

rootFinder

<void> destroy() Destroy the rootFinder object.

<double> find(<double> [rootGuess]|<double(2)> [rootRange]) Find the root of the function given an initial guess or range.

<logical> isInitialized() Return the initialization state of a rootFinder object.

<void> rangeExpand(<double> [rangeExpandUpward]→,<double> [rangeExpandDownward]→, <rangeExpand> [rangeExpandType]→, <double> [rangeUpwardLimit]→, <double> [rangeDownwardLimit]→, <rangeExpandSignExpect> [rangeExpandDownwardSignExpect]→, <rangeExpandSignExpect> [rangeExpandUpwa
Specify how the initial range will be expanded in a rootFinder object to bracket the root.

<void> rootFunction(<function(<double> x→)> rootFunction) Set the function that evaluates $f(x)$ to use in a rootFinder object.

<void> rootFunctionDerivative(<function(<double> x→)> rootFunction, <function(<double> x→)> rootFunctionDerivative, <void(<double> x→, <double> f→, <double> fdf→)> rootFunctionBoth)
Set the functions that evaluate $f(x)$ and derivatives to use in a rootFinder object.

<void> tolerance(<double> [toleranceAbsolute]→, <double> [toleranceRelative]→) Set the tolerance to use in a rootFinder object.

<void> type(<type(fgsl_root_fsolver_type)> solverType→) Set the type of algorithm to use in a rootFinder object.

<void> typeDerivative(<type(fgsl_root_fdfsolver_type)> solverDerivativeType→) Set the type of algorithm to use in a rootFinder object in cases where the derivative of the function is available.

satelliteDynamicalFrictionChandrasekhar1943

double precision, dimension(3) acceleration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the satellite acceleration due to dynamical friction for node (in units of km/s/Gyr).

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteDynamicalFrictionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

satelliteDynamicalFrictionClass

double precision, dimension(3) acceleration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the satellite acceleration due to dynamical friction for node (in units of km/s/Gyr).

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((satelliteDynamicalFrictionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

satelliteDynamicalFrictionZero

`double precision, dimension(3) acceleration(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the satellite acceleration due to dynamical friction for `node` (in units of km/s/Gyr).

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((satelliteDynamicalFrictionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

satelliteMergingTimescalesBoylanKolchin2008

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout) Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteMergingTimescalesClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout) Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteMergingTimescalesInfinite

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout)
Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteMergingTimescalesJiang2008

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout) Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteMergingTimescalesLaceyCole1993

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout) Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

double precision timeUntilMergingMassDependence() Return the mass-dependent part of the time (in Gyr) until the satellite will merge with its host.

satelliteMergingTimescalesLaceyCole1993Tormen

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout) Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteMergingTimescalesWetzelWhite2010

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout)
Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteMergingTimescalesZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteMergingTimescalesClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timeUntilMerging(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless type((keplerOrbit))\textgreater} orbit\arginout)
Return the time (in Gyr) until the satellite will merge with its host given the current orbit.

satelliteOrphanDistributionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteOrphanDistributionClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision extent(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
The maximum extent of the distribution, i.e. the radius of a sphere centered on the host halo which encompasses all orphan satellites.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision, dimension(3) position(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Return the position of the given orphan in physical coordinates.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision, dimension(3) velocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the peculiar velocity of the given orphan in physical coordinates.

satelliteOrphanDistributionRandomIsotropic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteOrphanDistributionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision extent(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) The maximum extent of the distribution, i.e. the radius of a sphere centered on the host halo which encompasses all orphan satellites.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<double> inverseCumulativeMassFunctionRadial(textcolorred<type(treeNode)> node↔, <double> fraction→) Return the radius enclosing the given fraction of the orphan satellite population.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision, dimension(3) position(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the position of the given orphan in physical coordinates.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision, dimension(3) velocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the peculiar velocity of the given orphan in physical coordinates.

`<double> velocityDispersion(textcolorred<type(treeNode)> node↔)` Return the 1-D velocity dispersion of the orphan satellite population.

satelliteOrphanDistributionTraceDarkMatter

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((satelliteOrphanDistributionClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision extent(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` The maximum extent of the distribution, i.e. the radius of a sphere centered on the host halo which encompasses all orphan satellites.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<double> inverseCumulativeMassFunctionRadial(textcolorred<type(treeNode)> node↔, <double> fraction→)` Return the radius enclosing the given fraction of the orphan satellite population.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision, dimension(3) position(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the position of the given orphan in physical coordinates.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision, dimension(3) velocity(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the peculiar velocity of the given orphan in physical coordinates.

<double> velocityDispersion(textcolorred<type(treeNode)> node↔) Return the 1-D velocity dispersion of the orphan satellite population.

satelliteTidalFieldClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteTidalFieldClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision tidalTensorRadial(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the radial component, $\Phi_{\rm rr}$, of the tidal tensor, $\Phi_{\rm ab}$.

satelliteTidalFieldNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteTidalFieldClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision tidalTensorRadial(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Returns the radial component, $\Phi_{\rm rr}$, of the tidal tensor, $\Phi_{\rm ab}$.

satelliteTidalFieldSphericalSymmetry

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteTidalFieldClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision tidalTensorRadial(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout) Returns the radial component, $\Phi_{\rm rr}$, of the tidal tensor, $\Phi_{\rm ab}$.

satelliteTidalHeatingRateClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteTidalHeatingRateClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision heatingRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return the satellite tidal heating rate for node (in units of $(\mathrm{km/s/Mpc})^2/\mathrm{Gyr}$).

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

satelliteTidalHeatingRateGnedin1999

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((satelliteTidalHeatingRateClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision heatingRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return the satellite tidal heating rate for node (in units of $(\mathrm{km/s/Mpc})^2/\mathrm{Gyr}$).

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

satelliteTidalHeatingRateZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((satelliteTidalHeatingRateClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision heatingRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return the satellite tidal heating rate for `node` (in units of $(\mathrm{km/s/Mpc})^2/\mathrm{Gyr}$).

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

satelliteTidalStrippingClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((satelliteTidalStrippingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massLossRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of tidal mass loss for `node` (in units of $M_\odot/\mathrm{Gyr}$).

`type(varying_string) objectType()` Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

satelliteTidalStrippingZentner2005

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((satelliteTidalStrippingClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision massLossRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of tidal mass loss for node (in units of $M_\odot$/Gyr).

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

satelliteTidalStrippingZero

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((satelliteTidalStrippingClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision massLossRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of tidal mass loss for `node` (in units of $M_\odot$/Gyr).

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

semaphore

`<void> close()` Close the semaphore.

`<void> post()` Post to (i.e. release) a semaphore.

`<void> unlink()` Unlink a semaphore.

`<void> wait()` Wait for a semaphore to become available.

starFormationExpulsiveFeedbackDisksClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationExpulsiveFeedbackDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the disk component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationExpulsiveFeedbackDisksSuperWind

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationExpulsiveFeedbackDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex
double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double
precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the disk component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationExpulsiveFeedbackDisksZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationExpulsiveFeedbackDisksClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex
double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double
precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the disk component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationExpulsiveFeedbackSpheroidsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationExpulsiveFeedbackSpheroidsClass))\textgreat destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the spheroid component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationFeedbackDisksPowerLaw

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackDisksClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex
double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double
precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the disk component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> velocityCharacteristic(<type(treeNode)> node↔) Return the characteristic velocity for power law disk feedback models.

starFormationFeedbackDisksPowerLawRedshiftScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textlogical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textdouble precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the disk component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> velocityCharacteristic(<type(treeNode)> node↔) Return the characteristic velocity for power law disk feedback models.

starFormationFeedbackDisksVlctyMxSclng

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the disk component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationFeedbackSpheroidsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin)` Returns the outflow rate due to star formation in the spheroid component of `node` in units of $M_\odot$/Gyr.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

starFormationFeedbackSpheroidsFixed

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackSpheroidsClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin)` Returns the outflow rate due to star formation in the spheroid component of `node` in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationFeedbackSpheroidsPowerLaw

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the spheroid component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> velocityCharacteristic(<type(treeNode)> node↔) Return the characteristic velocity for power law spheroid feedback models.

starFormationFeedbackSpheroidsPowerLawRedshiftScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Returns the outflow rate due to star formation in the spheroid component of node in units of $M_\odot$/Gyr.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<double> velocityCharacteristic(<type(treeNode)> node↔) Return the characteristic velocity for power law spheroid feedback models.

starFormationFeedbackSpheroidsVlctyMxSclng

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((starFormationFeedbackSpheroidsClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision outflowRate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\tex double precision\textgreater} rateEnergyInput\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin)` Returns the outflow rate due to star formation in the spheroid component of `node` in units of $M_\odot$/Gyr.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

starFormationHistoryClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void create(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\text type((history ))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless double precision\textgreater} timeBegin\argin)` Create the star formation history object.

`void deepCopy(\textcolor{red}{\textless class((starFormationHistoryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void output(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex
logical\textgreater} nodePassesFilter\argin,\textcolor{red}{\textless type((history
))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} indexOutput\argin,\textcolor{red}{\textless integer((kind=kind_-
int8))\textgreater} indexTree\argin,\textcolor{red}{\textless character((len=*))\textgreater}
labelComponent\argin) Output the star formation history.

void rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textl
type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless
type((abundances))\textgreater} abundancesFuel\argin,\textcolor{red}{\textless double
precision\textgreater} rateStarFormation\argin) Record the rate of star formation in this
history.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the
new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void scales(\textcolor{red}{\textless type((history))\textgreater} historyStarFormation\arginout,\text
double precision\textgreater} massStellar\argin,\textcolor{red}{\textless type((abundances))\textgr
abundancesStellar\argin) Set ODE solver absolute scales for a star formation history object.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationHistoryInSitu

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names al-
lowed for this object.

void autoHook() Insert any event hooks required by this object.

void create(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\text
type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless
double precision\textgreater} timeBegin\argin) Create the star formation history object.

void deepCopy(\textcolor{red}{\textless class((starFormationHistoryClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which
could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

<void> make(<type(history)> historyStarFormation↔, <double> timeBegin→, <double> timeEnd→,
<double(:)> [timesCurrent]) Make the star formation history.

type(varying_string) objectType() Return the type of the object.

void output(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex
logical\textgreater} nodePassesFilter\argin,\textcolor{red}{\textless type((history
))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} indexOutput\argin,\textcolor{red}{\textless integer((kind=kind_-
int8))\textgreater} indexTree\argin,\textcolor{red}{\textless character((len=*))\textgreater}
labelComponent\argin) Output the star formation history.

void rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textl
type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless
type((abundances))\textgreater} abundancesFuel\argin,\textcolor{red}{\textless double
precision\textgreater} rateStarFormation\argin) Record the rate of star formation in this
history.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the
new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void scales(\textcolor{red}{\textless type((history))\textgreater} historyStarFormation\arginout,\text
double precision\textgreater} massStellar\argin,\textcolor{red}{\textless type((abundances))\textgr
abundancesStellar\argin) Set ODE solver absolute scales for a star formation history object.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationHistoryMetallicitySplit

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names al-
lowed for this object.

void autoHook() Insert any event hooks required by this object.

void create(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\text
type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless
double precision\textgreater} timeBegin\argin) Create the star formation history object.

void deepCopy(\textcolor{red}{\textless class((starFormationHistoryClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

<void> make(<type(history)> historyStarFormation↔, <double> timeBegin→, <double> timeEnd→, <double(:)> [timesCurrent]) Make the star formation history.

type(varying_string) objectType() Return the type of the object.

void output(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex logical\textgreater} nodePassesFilter\argin,\textcolor{red}{\textless type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless integer((c_-size_t))\textgreater} indexOutput\argin,\textcolor{red}{\textless integer((kind=kind_-int8))\textgreater} indexTree\argin,\textcolor{red}{\textless character((len=*))\textgreater} labelComponent\argin) Output the star formation history.

void rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textl type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless type((abundances))\textgreater} abundancesFuel\argin,\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin) Record the rate of star formation in this history.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void scales(\textcolor{red}{\textless type((history))\textgreater} historyStarFormation\arginout,\text double precision\textgreater} massStellar\argin,\textcolor{red}{\textless type((abundances))\textgr abundancesStellar\argin) Set ODE solver absolute scales for a star formation history object.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationHistoryNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void create(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\text
type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless
double precision\textgreater} timeBegin\argin) Create the star formation history object.

void deepCopy(\textcolor{red}{\textless class((starFormationHistoryClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which
could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void output(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\tex
logical\textgreater} nodePassesFilter\argin,\textcolor{red}{\textless type((history
))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} indexOutput\argin,\textcolor{red}{\textless integer((kind=kind_-
int8))\textgreater} indexTree\argin,\textcolor{red}{\textless character((len=*))\textgreater}
labelComponent\argin) Output the star formation history.

void rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textl
type((history))\textgreater} historyStarFormation\arginout,\textcolor{red}{\textless
type((abundances))\textgreater} abundancesFuel\argin,\textcolor{red}{\textless double
precision\textgreater} rateStarFormation\argin) Record the rate of star formation in this
history.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the
new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void scales(\textcolor{red}{\textless type((history))\textgreater} historyStarFormation\arginout,\text
double precision\textgreater} massStellar\argin,\textcolor{red}{\textless type((abundances))\textgr
abundancesStellar\argin) Set ODE solver absolute scales for a star formation history object.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

starFormationRateSurfaceDensityDisksBlitz2006

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((starFormationRateSurfaceDensityDisksClass))\textgreater]
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision, allocatable, dimension(:,:) intervals(\textcolor{red}{\textless type((treeNode))\text
node\arginout,\textcolor{red}{\textless double precision\textgreater} radiusInner\argin,\textcolor{
double precision\textgreater} radiusOuter\argin) Return a set of integration intervals to use when integrating over the surface density of star formation rate.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{
double precision\textgreater} radius\argin) Returns the star formation rate surface density (in $M_\odot$ Gyr^{-1} Mpc^{-2}) in the disk component of thisNode at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical unchanged(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return true if the surface density rate of star formation is unchanged since the previous evaluation.

starFormationRateSurfaceDensityDisksClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((starFormationRateSurfaceDensityDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision, allocatable, dimension(:,:) intervals(\textcolor{red}{\textless type((treeNode))\text node\arginout,\textcolor{red}{\textless double precision\textgreater} radiusInner\argin,\textcolor{ double precision\textgreater} radiusOuter\argin)` Return a set of integration intervals to use when integrating over the surface density of star formation rate.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ double precision\textgreater} radius\argin)` Returns the star formation rate surface density (in $M_\odot$ Gyr^{-1} Mpc^{-2}) in the disk component of `thisNode` at the given `radius`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`logical unchanged(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return true if the surface density rate of star formation is unchanged since the previous evaluation.

starFormationRateSurfaceDensityDisksExtendedSchmidt

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((starFormationRateSurfaceDensityDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision, allocatable, dimension(:,:) intervals(\textcolor{red}{\textless type((treeNode))\text node\arginout,\textcolor{red}{\textless double precision\textgreater} radiusInner\argin,\textcolor{ double precision\textgreater} radiusOuter\argin) Return a set of integration intervals to use when integrating over the surface density of star formation rate.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ double precision\textgreater} radius\argin) Returns the star formation rate surface density (in $M_\odot$ Gyr^{-1} Mpc^{-2}) in the disk component of thisNode at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

logical unchanged(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Return true if the surface density rate of star formation is unchanged since the previous evaluation.

starFormationRateSurfaceDensityDisksKennicuttSchmidt

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((starFormationRateSurfaceDensityDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`double precision, allocatable, dimension(:,:) intervals(\textcolor{red}{\textless type((treeNode))\text node\arginout,\textcolor{red}{\textless double precision\textgreater} radiusInner\argin,\textcolor{ double precision\textgreater} radiusOuter\argin)` Return a set of integration intervals to use when integrating over the surface density of star formation rate.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{ double precision\textgreater} radius\argin)` Returns the star formation rate surface density (in $M_\odot$ Gyr^{-1} Mpc^{-2}) in the disk component of `thisNode` at the given `radius`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`logical unchanged(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Return true if the surface density rate of star formation is unchanged since the previous evaluation.

starFormationRateSurfaceDensityDisksKrumholz2009

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

`<void> computeFactors()` Compute constant factors required.

`void deepCopy(\textcolor{red}{\textless class((starFormationRateSurfaceDensityDisksClass))\textgreater destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision, allocatable, dimension(:,:) intervals(\textcolor{red}{\textless type((treeNode))\text
node\arginout,\textcolor{red}{\textless double precision\textgreater} radiusInner\argin,\textcolor{
double precision\textgreater} radiusOuter\argin) Return a set of integration intervals to use when integrating over the surface density of star formation rate.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rate(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{
double precision\textgreater} radius\argin) Returns the star formation rate surface density (in $M_\odot$ Gyr^{-1} Mpc^{-2}) in the disk component of thisNode at the given radius.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> surfaceDensityFactors() Compute surface density factors required.

logical unchanged(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Return true if the surface density rate of star formation is unchanged since the previous evaluation.

starFormationTimescaleDisksBaugh2005

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleDisksClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleDisksDynamicalTime

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleDisksFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleDisksHaloScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleDisksIntgrtdSurfaceDensity

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleDisksVelocityMaxScaling

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> calculationReset(<type(table)> node↔) Reset memoized calculations.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the timescale (in Gyr) for star formation in the disk component of node.

starFormationTimescaleSpheroidsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the timescale (in Gyr) for star formation in the spheroid component of node.

starFormationTimescaleSpheroidsDynamicalTime

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleSpheroidsClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the timescale (in Gyr) for star formation in the spheroid component of `node`.

starFormationTimescaleSpheroidsVelocityMaxScaling

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`<void> calculationReset(<type(table)> node↔)` Reset memoized calculations.

`void deepCopy(\textcolor{red}{\textless class((starFormationTimescaleSpheroidsClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision timescale(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the timescale (in Gyr) for star formation in the spheroid component of `node`.

stellarAstrophysicsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarAstrophysicsClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision lifetime(\textcolor{red}{\textless double precision\textgreater} massInitial\argin,\te
double precision\textgreater} metallicity\argin) Returns the lifetime of a star of given massInitial and metallicity.

double precision massEjected(\textcolor{red}{\textless double precision\textgreater} massInitial\argin,
double precision\textgreater} metallicity\argin) Returns the mass ejected by a star of given massInitial and metallicity.

double precision massInitial(\textcolor{red}{\textless double precision\textgreater} lifetime\argin,\te
double precision\textgreater} metallicity\argin) Returns the initial mass of a star of given lifetime and metallicity.

double precision massYield(\textcolor{red}{\textless double precision\textgreater} massInitial\argin,\t
double precision\textgreater} metallicity\argin,\textcolor{red}{\textless integer\textgreater}
atomIndex\argin) Returns the metal mass yielded by a star of given massInitial and metallicity.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarAstrophysicsFile

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarAstrophysicsClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision lifetime(\textcolor{red}{\textless double precision\textgreater} massInitial\argin,\te double precision\textgreater} metallicity\argin)` Returns the lifetime of a star of given `massInitial` and `metallicity`.

`double precision massEjected(\textcolor{red}{\textless double precision\textgreater} massInitial\argin, double precision\textgreater} metallicity\argin)` Returns the mass ejected by a star of given `massInitial` and `metallicity`.

`double precision massInitial(\textcolor{red}{\textless double precision\textgreater} lifetime\argin,\te double precision\textgreater} metallicity\argin)` Returns the initial mass of a star of given `lifetime` and `metallicity`.

`double precision massYield(\textcolor{red}{\textless double precision\textgreater} massInitial\argin,\t double precision\textgreater} metallicity\argin,\textcolor{red}{\textless integer\textgreater} atomIndex\argin)` Returns the metal mass yielded by a star of given `massInitial` and `metallicity`.

`type(varying_string) objectType()` Return the type of the object.

`<void> read()` Read stellar astrophysics data from file.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarFeedbackClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarFeedbackClass))\textgreater} destination\arginout
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision energyInputCumulative(\textcolor{red}{\textless double precision\textgreater}
initialMass\argin,\textcolor{red}{\textless double precision\textgreater} age\argin,\textcolor{red}
double precision\textgreater} metallicity\argin) Return the cumulative energy input from a stellar population of the given initialMass, age, and metallicity.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarFeedbackStandard

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarFeedbackClass))\textgreater} destination\arginout
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision energyInputCumulative(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin) Return the cumulative energy input from a stellar population of the given initialMass, age, and metallicity.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarLuminosities

<type(stellarLuminosities)> add(<type(stellarLuminosities)> stellarLuminosities2→) Add two stellarLuminosities.

<void> builder(<*type(node)> stellarLuminositiesDefinition→) Build a stellar luminosities object from a provided XML description.

<void> deserialize(<double(:)> array→) Deserialize a stellar luminosities object from an array.

<void> destroy() Destroy a stellar luminosities object.

<type(stellarLuminosities)> divide(<double> divisor→) Divide stellar luminosities by a scalar.

<void> dump() Dump a stellar luminosities object.

<void> dumpRaw(<integer> fileHandle→) Dump a stellar luminosities object to binary.

<void> increment(<type(stellarLuminosities)> addStellarLuminosities→) Increment a stellar luminosities object.

<integer> index(<type(varying_string)> name→) Return the index to a luminosity specified by name.

<logical> isOutput(<integer> index→, <double> time→) Return true if the indexed luminosity is to be output at the given time.

<logical> isZero() Return true if a stellar luminosities object is zero.

<double> luminosity(<integer> index→) Return the i^{th} luminosity.

<integer> luminosityCount(<logical> [unmapped]) Return the total number of luminosities tracked. If unmapped is true, then the number of luminosities prior to mapping is returned.

<integer> luminosityOutputCount(<double> time→) Return the number of luminosities to be output at the given time.

<type(stellarLuminosities)> multiply(<double> multiplier→) Multiply stellar luminosities by a scalar.

<type(varying_string)> name(<integer> index→) Return the name of a luminosity specified by index.

<integer(c_size_t) > nonStaticSizeOf() Returns the size of any non-static components of the type.

<void> output(<integer> integerProperty↔, <integer> integerBufferCount↔, <integer(:,:)> integerBuffer↔, <integer>doubleProperty↔, <integer> doubleBufferCount↔, <double(:,:)> doubleBuffer↔, <double> time→, <integer> instance→) Store a stellar luminosities object in the output buffers.

<void> outputCount(<integer> integerPropertyCount↔, <integer> doublePropertyCount↔, <double> time→, <integer> instance→) Specify the count of a stellar luminosities object for output.

<void> outputNames(<integer> integerProperty↔, <char[*](:)> integerPropertyNames↔, <char[*](:)> integerPropertyComments↔, <double(:)> integerPropertyUnitsSI↔, <integer> doubleProperty↔, <char[*](:)> doublePropertyNames↔, <char[*](:)> doublePropertyComments↔, <double(:)> doublePropertyUnitsSI↔, <double> time→, <integer> instance→) Specify the names of stellar luminosities object properties for output.

<void> postOutput(<double> time→) Store a stellar luminosities object in the output buffers.

<void> readRaw(<integer> fileHandle→) Read a stellar luminosities object from binary.

<void> reset() Reset a stellar luminosities object.

<void> serialize(<double(:)> array←) Serialize a stellar luminosities object to an array.

<integer> serializeCount() Return a count of the number of properties in a serialized stellar luminosities object.

<void> setLuminosities(<double> mass→,<class(stellarPopulationClass) stellarPopulation_↔,<double>currentTime→,<type(abundances)> fuelAbundances→) Set the luminosities using a single stellar population.

<void> setToUnity() Set a stellar luminosities object to unity.

<type(stellarLuminosities)> subtract(<type(stellarLuminosities)> stellarLuminosities2→) Subtract one abundance from another.

<void> truncate(<type(stellarLuminosities)> templateLuminosities→) Truncate the number of stellar luminosities stored to match that in the given templateLuminosities.

stellarPopulationClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationClass))\textgreater} destination\argino` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rateEnergy(\textcolor{red}{\textless type((abundances))\textgreater} abundances_- \argin,\textcolor{red}{\textless double precision\textgreater} ageMinimum\argin,\textcolor{red}{\te double precision\textgreater} ageMaximum\argin)` Return the rate of energy input from this population.

`double precision rateRecycling(\textcolor{red}{\textless type((abundances))\textgreater} abundances_ \argin,\textcolor{red}{\textless double precision\textgreater} ageMinimum\argin,\textco double precision\textgreater} ageMaximum\argin)` Return the rate of recycling from this population.

`double precision rateYield(\textcolor{red}{\textless type((abundances))\textgreater} abundances_- \argin,\textcolor{red}{\textless double precision\textgreater} ageMinimum\argin,\textcolor{red}{\te double precision\textgreater} ageMaximum\argin,\textcolor{red}{\textless integer\textgreater} elementIndex \argin)` Return the rate of element yield from this population.

`double precision recycledFractionInstantaneous()` Return the recycled fraction from this population in the instantaneous approximation.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`class(stellarPopulationSpectraClass) spectra()` Return at set of stellar spectra for this population.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

integer(c_size_t) uniqueID() Return the uniqueID corresponding to this population.

double precision yieldInstantaneous() Return the metal yield from this population in the instantaneous approximation.

stellarPopulationPropertiesClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationPropertiesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

integer historyCount() Return the number of stellar population property histories which must be stored.

void historyCreate(\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout,\textcolor{re type((history))\textgreater} history_\arginout) Create histories needed to store stellar population properties.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void rates(\textcolor{red}{\textless double precision\textgreater} rateStarFormation \argin,\textcolor{ type((abundances))\textgreater} abundancesFuel \argin,\textcolor{red}{\textless class((nodeCompone))\textgreater} component \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout,\textcolor{red}{\textless type((history))\textgreater} history_ \arginout,\textcolo double precision\textgreater} rateMassStellar\argout,\textcolor{red}{\textless double precision\textgreater} rateMassFuel\argout,\textcolor{red}{\textless double precision\textgreater} rateEnergyInput\argout,\textcolor{red}{\textless type((abundances))\textgreater} rateAbundancesFue type((abundances))\textgreater} rateAbundancesStellar \arginout,\textcolor{red}{\textless type((stellarLuminosities))\textgreater} rateLuminosityStellar \arginout,\textcolor{red}{\textless logical\textgreater} computeRateLuminosityStellar \argin) Returns rates of change of stellar population properties.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void scales(\textcolor{red}{\textless double precision\textgreater} massStellar \argin,\textcolor{red}{\textless type((abundances))\textgreater} abundancesStellar\argin,\textcolor{red}{\textless type((history ))\textgreater} history_ \arginout)` Return scaling factors of stellar population properties for an ODE solver.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarPopulationPropertiesInstantaneous

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationPropertiesClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`integer historyCount()` Return the number of stellar population property histories which must be stored.

`void historyCreate(\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout,\textcolor{re type((history ))\textgreater} history_\arginout)` Create histories needed to store stellar population properties.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void rates(\textcolor{red}{\textless double precision\textgreater} rateStarFormation \argin,\textcolor type((abundances))\textgreater} abundancesFuel \argin,\textcolor{red}{\textless class((nodeCompone))\textgreater} component \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout,\textcolor{red}{\textless type((history))\textgreater} history_ \arginout,\textcolo double precision\textgreater} rateMassStellar\argout,\textcolor{red}{\textless double precision\textgreater} rateMassFuel\argout,\textcolor{red}{\textless double precision\textgreater} rateEnergyInput\argout,\textcolor{red}{\textless type((abundances))\textgreater} rateAbundancesFue type((abundances))\textgreater} rateAbundancesStellar \arginout,\textcolor{red}{\textless type((stellarLuminosities))\textgreater} rateLuminosityStellar \arginout,\textcolor{red}{\textless logical\textgreater} computeRateLuminosityStellar \argin)` Returns rates of change of stellar population properties.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void scales(\textcolor{red}{\textless double precision\textgreater} massStellar \argin,\textcolor{red}{\textless type((abundances))\textgreater} abundancesStellar\argin,\textcolor{red}{\textless type((history))\textgreater} history_ \arginout) Return scaling factors of stellar population properties for an ODE solver.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationPropertiesNoninstantaneous

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationPropertiesClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textlogical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

integer historyCount() Return the number of stellar population property histories which must be stored.

void historyCreate(\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout,\textcolor{retype((history))\textgreater} history_\arginout) Create histories needed to store stellar population properties.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void rates(\textcolor{red}{\textless double precision\textgreater} rateStarFormation \argin,\textcolor{type((abundances))\textgreater} abundancesFuel \argin,\textcolor{red}{\textless class((nodeCompone))\textgreater} component \argin,\textcolor{red}{\textless type((treeNode))\textgreater} node \arginout,\textcolor{red}{\textless type((history))\textgreater} history_ \arginout,\textcolodouble precision\textgreater} rateMassStellar\argout,\textcolor{red}{\textless double precision\textgreater} rateMassFuel\argout,\textcolor{red}{\textless double precision\textgreater}

rateEnergyInput\argout,\textcolor{red}{\textless type((abundances))\textgreater} rateAbundancesFue
type((abundances))\textgreater} rateAbundancesStellar \arginout,\textcolor{red}{\textless
type((stellarLuminosities))\textgreater} rateLuminosityStellar \arginout,\textcolor{red}{\textless
logical\textgreater} computeRateLuminosityStellar \argin) Returns rates of change of stellar population properties.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void scales(\textcolor{red}{\textless double precision\textgreater} massStellar \argin,\textcolor{red}{
type((abundances))\textgreater} abundancesStellar\argin,\textcolor{red}{\textless type((history
))\textgreater} history_ \arginout) Return scaling factors of stellar population properties for an ODE solver.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSelectorClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSelectorClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isStarFormationRateDependent() Return true if the selection of stellar population is dependent on star formation rate.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

class(stellarPopulationClass) select(\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin,\textcolor{red}{\textless type((abundances))\textgreater} abundances_ \argin,\textcolor{red}{\textless class((nodeComponent))\textgreater} component \argin) Return a stellar population.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSelectorDiskSpheroid

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSelectorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isStarFormationRateDependent() Return true if the selection of stellar population is dependent on star formation rate.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

class(stellarPopulationClass) select(\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin,\textcolor{red}{\textless type((abundances))\textgreater} abundances_ \argin,\textcolor{red}{\textless class((nodeComponent))\textgreater} component \argin) Return a stellar population.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSelectorFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSelectorClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

logical isStarFormationRateDependent() Return true if the selection of stellar population is dependent on star formation rate.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

class(stellarPopulationClass) select(\textcolor{red}{\textless double precision\textgreater} rateStarFormation\argin,\textcolor{red}{\textless type((abundances))\textgreater} abundances_ \argin,\textcolor{red}{\textless class((nodeComponent))\textgreater} component \argin) Return a stellar population.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision luminosity(\textcolor{red}{\textless type((abundances))\textgreater} abundancesStellar double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Return the luminosity (in units of $L_\odot$ Hz^{-1}) for a stellar population, composition `abundances`, of the given `age` (in Gyr), at the specified `wavelength` (in Angstroms).

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulation(\textcolor{red}{\textless integer\textgreater} agesCount\argout,\textcolor{red}{\textle integer\textgreater} metallicitiesCount\argout,\textcolor{red}{\textless double precision\textgreat ages\argout,\textcolor{red}{\textless double precision\textgreater} metallicity\argout)` Return a tabulation of ages and metallicities at which stellar spectra should be tabulated.

`double precision wavelengthInterval(\textcolor{red}{\textless double precision\textgreater} wavelength\argin)` At a given wavelength, return the wavelength interval in the tabulation of wavelength for which stellar spectra are defined.

`void wavelengths(\textcolor{red}{\textless integer\textgreater} wavelengthsCount\argout,\textcolor{red} double precision\textgreater} wavelengths\argout)` Return a tabulation of wavelengths at which stellar spectra are defined.

stellarPopulationSpectraFile

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision luminosity(\textcolor{red}{\textless type((abundances))\textgreater} abundancesStellar double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Return the luminosity (in units of $L_\odot$ Hz^{-1}) for a stellar population, composition `abundances`, of the given `age` (in Gyr), at the specified `wavelength` (in Angstroms).

`type(varying_string) objectType()` Return the type of the object.

`void readFile(<char(len=*)> fileName→)` Read the named stellar population spectra file.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulation(\textcolor{red}{\textless integer\textgreater} agesCount\argout,\textcolor{red}{\textle integer\textgreater} metallicitiesCount\argout,\textcolor{red}{\textless double precision\textgreat ages\argout,\textcolor{red}{\textless double precision\textgreater} metallicity\argout)` Return a tabulation of ages and metallicities at which stellar spectra should be tabulated.

`double precision wavelengthInterval(\textcolor{red}{\textless double precision\textgreater} wavelength\argin)` At a given wavelength, return the wavelength interval in the tabulation of wavelength for which stellar spectra are defined.

`void wavelengths(\textcolor{red}{\textless integer\textgreater} wavelengthsCount\argout,\textcolor{red} double precision\textgreater} wavelengths\argout)` Return a tabulation of wavelengths at which stellar spectra are defined.

stellarPopulationSpectraFSPS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision luminosity(\textcolor{red}{\textless type((abundances))\textgreater} abundancesStellar double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\textcolor{red}{\textless integer\textgreater} status\argout)` Return the luminosity (in units of $L_\odot$ Hz^{-1}) for a stellar population, composition `abundances`, of the given `age` (in Gyr), at the specified `wavelength` (in Angstroms).

`type(varying_string) objectType()` Return the type of the object.

`void readFile(<char(len=*)> fileName→)` Read the named stellar population spectra file.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`void tabulation(\textcolor{red}{\textless integer\textgreater} agesCount\argout,\textcolor{red}{\textle integer\textgreater} metallicitiesCount\argout,\textcolor{red}{\textless double precision\textgreat ages\argout,\textcolor{red}{\textless double precision\textgreater} metallicity\argout)` Return a tabulation of ages and metallicities at which stellar spectra should be tabulated.

`double precision wavelengthInterval(\textcolor{red}{\textless double precision\textgreater} wavelength\argin)` At a given wavelength, return the wavelength interval in the tabulation of wavelength for which stellar spectra are defined.

`void wavelengths(\textcolor{red}{\textless integer\textgreater} wavelengthsCount\argout,\textcolor{red} double precision\textgreater} wavelengths\argout)` Return a tabulation of wavelengths at which stellar spectra are defined.

stellarPopulationSpectraPostprocessorBuilderClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`class(stellarPopulationSpectraPostprocessorClass) build(\textcolor{red}{\textless type((varying_string))\textgreater} descriptor\argin)` Build and return a postprocessor.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorBuilderClass))\text destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_ size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_ size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarPopulationSpectraPostprocessorBuilderLookup

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`class(stellarPopulationSpectraPostprocessorClass) build(\textcolor{red}{\textless type((varying_string))\textgreater} descriptor\argin)` Build and return a postprocessor.

`void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorBuilderClass))\text destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorIdentity

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorInoue2014

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorLycSuppress

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorMadau1995

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreate
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorMeiksin2006

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorRecent

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorSequence

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreater
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationSpectraPostprocessorUnescaped

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationSpectraPostprocessorClass))\textgreate
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision multiplier(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\t
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
redshift\argin) Return the multiplicative modification to the spectrum.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarPopulationStandard

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarPopulationClass))\textgreater} destination\argino Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> interpolate(<type(abundances)> abundances_→, <double> ageMinimum→,<double> ageMaximum→, <type(populationTable)> property↔) Interpolate in the given property to return the mean rate of production of that property from the stellar population between the given minimum and maximum ages.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateEnergy(\textcolor{red}{\textless type((abundances))\textgreater} abundances_- \argin,\textcolor{red}{\textless double precision\textgreater} ageMinimum\argin,\textcolor{red}{\te double precision\textgreater} ageMaximum\argin) Return the rate of energy input from this population.

double precision rateRecycling(\textcolor{red}{\textless type((abundances))\textgreater} abundances_ \argin,\textcolor{red}{\textless double precision\textgreater} ageMinimum\argin,\textco double precision\textgreater} ageMaximum\argin) Return the rate of recycling from this population.

double precision rateYield(\textcolor{red}{\textless type((abundances))\textgreater} abundances_- \argin,\textcolor{red}{\textless double precision\textgreater} ageMinimum\argin,\textcolor{red}{\te double precision\textgreater} ageMaximum\argin,\textcolor{red}{\textless integer\textgreater} elementIndex \argin) Return the rate of element yield from this population.

double precision recycledFractionInstantaneous() Return the recycled fraction from this population in the instantaneous approximation.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

class(stellarPopulationSpectraClass) spectra() Return at set of stellar spectra for this population.

<logical> starIsEvolved(<double> massInitial→, <double> metallicity→,<double> age→) Return true if the star of given initial mass and metallicity has evolved off of the main sequence by the given age.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

integer(c_size_t) uniqueID() Return the uniqueID corresponding to this population.

double precision yieldInstantaneous() Return the metal yield from this population in the instantaneous approximation.

stellarSpectraDustAttenuationCalzetti2000

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\ double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin) Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

logical isAgeDependent() Return true if the attenuation may depend on the age of the stellar population.

<logical> isDefault() Return true if this is the default object of this class.

`logical isSeparable()` Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarSpectraDustAttenuationCardelli1989

`<double> a(<double> x→)` Return fitting function $a(x)$ for the dust attenuation model of Cardelli et al. [1989].

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\ double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin)` Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

`void autoHook()` Insert any event hooks required by this object.

`<double> b(<double> x→)` Return fitting function $b(x)$ for the dust attenuation model of Cardelli et al. [1989].

`void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isAgeDependent()` Return true if the attenuation may depend on the age of the stellar population.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isSeparable()` Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarSpectraDustAttenuationCharlotFall2000

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\ double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin) Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

logical isAgeDependent() Return true if the attenuation may depend on the age of the stellar population.

<logical> isDefault() Return true if this is the default object of this class.

logical isSeparable() Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarSpectraDustAttenuationClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\ double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin)` Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isAgeDependent()` Return true if the attenuation may depend on the age of the stellar population.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isSeparable()` Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarSpectraDustAttenuationGordon2003

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
vBandAttenuation\argin) Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

logical isAgeDependent() Return true if the attenuation may depend on the age of the stellar population.

<logical> isDefault() Return true if this is the default object of this class.

logical isSeparable() Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarSpectraDustAttenuationPrevotBouchet

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

`double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\ double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin)` Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isAgeDependent()` Return true if the attenuation may depend on the age of the stellar population.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isSeparable()` Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarSpectraDustAttenuationTabulated

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\ double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin)` Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`logical isAgeDependent()` Return true if the attenuation may depend on the age of the stellar population.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isSeparable()` Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

stellarSpectraDustAttenuationWittGordon2000

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin, double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} vBandAttenuation\argin)` Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

logical isAgeDependent() Return true if the attenuation may depend on the age of the stellar population.

<logical> isDefault() Return true if this is the default object of this class.

logical isSeparable() Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarSpectraDustAttenuationZero

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision attenuation(\textcolor{red}{\textless double precision\textgreater} wavelength\argin,\
double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater}
vBandAttenuation\argin) Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarSpectraDustAttenuationClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

logical isAgeDependent() Return true if the attenuation may depend on the age of the stellar population.

<logical> isDefault() Return true if this is the default object of this class.

logical isSeparable() Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

stellarTracksClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarTracksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision luminosity(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\ double precision\textgreater} metallicity\argin,\textcolor{red}{\textless double precision\textgrea age\argin) Returns the bolometric luminosity of a star of given initialMass, metallicity and age.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperatureEffective(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin,\textcc double precision\textgreater} age\argin) Returns the effective temperature of a star of given initialMass, metallicity and age.

stellarTracksFile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarTracksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<double> interpolate() <integer(c_size_t)(2)> interpolationIndicesMetallicity→, <integer(c_size_- t)(2,2)> interpolationIndicesMass→, <integer(c_size_t)(2,2,2)> interpolationIndicesAge→, <double(2)> interpolationFactorsMetallicity→, <double(2,2)> interpolationFactorsMass→, <double(2,2,2)> interpolationFactorsAge→, <double(:,:,:)> stellarTracks→

<void> interpolationCompute() <integer(c_size_t)(2)> interpolationIndicesMetallicity←, <integer(c_- size_t)(2,2)> interpolationIndicesMass←, <integer(c_size_t)(2,2,2)> interpolationIndicesAge←, <double(2)> interpolationFactorsMetallicity←, <double(2,2)> interpolationFactorsMass←, <double(2,2,2)> interpolationFactorsAge←, <logical> metallicityOutOfRange←, <logical> massOut- OfRange←, <logical> ageOutOfRange←

<logical> isDefault() Return true if this is the default object of this class.

double precision luminosity(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\ double precision\textgreater} metallicity\argin,\textcolor{red}{\textless double precision\textgrea age\argin) Returns the bolometric luminosity of a star of given initialMass, metallicity and age.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision temperatureEffective(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin,\textcc double precision\textgreater} age\argin) Returns the effective temperature of a star of given initialMass, metallicity and age.

stellarWindsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarWindsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless double precision\textgreater} initialMass\argin double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin) Return the mass loss rate (in $M_\odot$/Gyr) from stars of given initialMass, age and metallicity.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTerminal(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin) Return the terminal velocity (in km/s) of winds from stars of given initialMass, age and metallicity.

stellarWindsLeitherer1992

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\[1] character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((stellarWindsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex[1] logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges[1] Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless double precision\textgreater} initialMass\argin[1] double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin) Return the mass loss rate (in $M_\odot$/Gyr) from stars of given initialMass, age and metallicity.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textless type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTerminal(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin) Return the terminal velocity (in km/s) of winds from stars of given initialMass, age and metallicity.

supernovaePopulationIIIClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((supernovaePopulationIIIClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision energyCumulative(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} age\argin,\textcolor{red} double precision\textgreater} metallicity\argin) Return the cumulative energy input from Population III supernovae from stars of given initialMass, age and metallicity.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

supernovaePopulationIIIHegerWoosley2002

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((supernovaePopulationIIIClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

`double precision energyCumulative(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textcolor{red}{\textless double precision\textgreater} age\argin,\textcolor{red} double precision\textgreater} metallicity\argin)` Return the cumulative energy input from Population III supernovae from stars of given `initialMass`, `age` and `metallicity`.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

supernovaeTypeIaClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((supernovaeTypeIaClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision number(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\text double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin)` Return the cumulative number of Type Ia supernovae from a stellar population of the given `initialMass`, `age`, and `metallicity`.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision yield(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textc double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin,\textcolor{red}{\textless integer\textgreater} atomIndex\argin) Return the cumulative yield from Type Ia supernoave from a stellar population of the given initialMass, age, and metallicity.

supernovaeTypeIaNagashima2005

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((supernovaeTypeIaClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision number(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\text double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin) Return the cumulative number of Type Ia supernovae from a stellar population of the given initialMass, age, and metallicity.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision yield(\textcolor{red}{\textless double precision\textgreater} initialMass\argin,\textc double precision\textgreater} age\argin,\textcolor{red}{\textless double precision\textgreater} metallicity\argin,\textcolor{red}{\textless integer\textgreater} atomIndex\argin)` Return the cumulative yield from Type Ia supernoave from a stellar population of the given `initialMass`, `age`, and `metallicity`.

surveyGeometryBaldry2012GAMA

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^{i} \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^{i}$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:)  > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryBernardi2013SDSS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin) Return the solid angle (in steradians) of the survey.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin) Returns the maximum volume (in Mpc^3) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

logical windowFunctionAvailable() Returns true if survey 3-D window functions are available.

void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red} double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryCaputi2011UKIDSSUDS

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin) Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

logical angularPowerAvailable() Returns true if angular power spectrum of survey window function is available.

integer angularPowerMaximumDegree() Return the maximum degree, ℓ_{max}, for which the angular power is available.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<void> randomsInitialize()` Initialize arrays of random points to define the survey angular geometry.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless`

complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t
integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)
Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^{i} \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^{i}$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

logical angularPowerAvailable() Returns true if angular power spectrum of survey window function is available.

integer angularPowerMaximumDegree() Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol
double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater}
field\argin) Returns the maximum distance (in Mpc) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol
double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater}
field\argin) Returns the minimum distance (in Mpc) at which a galaxy of the specified mass (in $M_\odot$) would be included in the survey.

integer fieldCount() Returns the number of distinct fields included in the survey.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re
double precision\textgreater} mass\argin) Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin) Return the solid angle (in steradians) of the survey.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin) Returns the maximum volume (in Mpc^3) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

logical windowFunctionAvailable() Returns true if survey 3-D window functions are available.

void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryCombined

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin) Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

logical angularPowerAvailable() Returns true if angular power spectrum of survey window function is available.

integer angularPowerMaximumDegree() Return the maximum degree, ℓ_{max}, for which the angular power is available.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout) Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red}{\textless double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryDavidzon2013VIPERS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\[\], \textcolor{red}{\textless character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\textless integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcolor{red}{\textless double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcolor{red}{\textless double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDigest\argin)` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical>` `isDefault()` Return true if this is the default object of this class.

`<type(varying_string) >` `mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:)  >` `mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer>` `referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void>` `referenceCountIncrement()` Increment the reference count to this object.

`<void>` `referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryFullSky

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red} double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryGunawardhana2013SDSS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red} double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window

functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryHearin2014SDSS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

<type(varying_string)(:) > mangleFiles() Return array of MANGLE filenames for this survey geometry.

type(varying_string) objectType() Return the type of the object.

logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re
double precision\textgreater} mass\argin) Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin) Return the solid angle (in steradians) of the survey.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin) Returns the maximum volume (in Mpc^3) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

logical windowFunctionAvailable() Returns true if survey 3-D window functions are available.

void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red
double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater}
gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor
complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless
complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryKelvin2014GAMAnear

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t
integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin) Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

logical angularPowerAvailable() Returns true if angular power spectrum of survey window function is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:)  > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red} double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryLiWhite2009SDSS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<void> randomsInitialize()` Initialize arrays of random points to define the survey angular geometry.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryLocalGroupClassical

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryLocalGroupDES

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red} double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryLocalGroupSDSS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater}`

field\argin) Returns the minimum distance (in Mpc) at which a galaxy of the specified mass (in $M_\odot$) would be included in the survey.

integer fieldCount() Returns the number of distinct fields included in the survey.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> initialize() Initialize an instance of the MANGLE survey geometry class.

<logical> isDefault() Return true if this is the default object of this class.

<type(varying_string) > mangleDirectory() Return the directory containing MANGLE files for this survey geometry.

<type(varying_string)(:) > mangleFiles() Return array of MANGLE filenames for this survey geometry.

type(varying_string) objectType() Return the type of the object.

logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin) Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin) Return the solid angle (in steradians) of the survey.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin) Returns the maximum volume (in Mpc^3) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

logical windowFunctionAvailable() Returns true if survey 3-D window functions are available.

void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryMangle

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryMartin2010ALFALFA

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<void> randomsInitialize()` Initialize arrays of random points to define the survey angular geometry.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red}{\textless double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryMonteroDorta2009SDSS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\textless integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\textcolor{red}{\textless logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcolor{red}{\textless double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcolor{red}{\textless double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges`
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re`
`double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)`
Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl`
`type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-`
`size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles`
`type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-`
`size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater}`
`mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red`
`double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater}`
`gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor`
`complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless`
`complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryMoustakas2013PRIMUS

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t
integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)
Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

logical angularPowerAvailable() Returns true if angular power spectrum of survey window function is available.

integer angularPowerMaximumDegree() Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol
double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater}
field\argin) Returns the maximum distance (in Mpc) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol
double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater}
field\argin) Returns the minimum distance (in Mpc) at which a galaxy of the specified mass (in $M_\odot$) would be included in the survey.

integer fieldCount() Returns the number of distinct fields included in the survey.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<void> initialize() Initialize an instance of the MANGLE survey geometry class.

<logical> isDefault() Return true if this is the default object of this class.

<type(varying_string) > mangleDirectory() Return the directory containing MANGLE files for this survey geometry.

<type(varying_string)(:) > mangleFiles() Return array of MANGLE filenames for this survey geometry.

type(varying_string) objectType() Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryMuzzin2013ULTRAVISTA

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

`logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin)` Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin)` Return the solid angle (in steradians) of the survey.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`logical windowFunctionAvailable()` Returns true if survey 3-D window functions are available.

`void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout)` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryRandomPoints

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the i^{th} field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, ℓ_{max}, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater}`

field\argin) Returns the minimum distance (in Mpc) at which a galaxy of the specified mass (in $M_\odot$) would be included in the survey.

integer fieldCount() Returns the number of distinct fields included in the survey.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re double precision\textgreater} mass\argin) Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

<void> randomsInitialize() Initialize arrays of random points to define the survey angular geometry.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin) Return the solid angle (in steradians) of the survey.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin) Returns the maximum volume (in Mpc^3) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

logical windowFunctionAvailable() Returns true if survey 3-D window functions are available.

void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

surveyGeometryTomczak2014ZFOURGE

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`double precision angularPower(\textcolor{red}{\textless integer\textgreater} i\argin,\textcolor{red}{\t integer\textgreater} j\argin,\textcolor{red}{\textless integer\textgreater} l\argin)` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field.

`logical angularPowerAvailable()` Returns true if angular power spectrum of survey window function is available.

`integer angularPowerMaximumDegree()` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((surveyGeometryClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision distanceMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected.

`double precision distanceMinimum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} magnitudeAbsolute\argin,\textcol double precision\textgreater} luminosity\argin,\textcolor{red}{\textless integer\textgreater} field\argin)` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey.

`integer fieldCount()` Returns the number of distinct fields included in the survey.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<void> initialize()` Initialize an instance of the MANGLE survey geometry class.

`<logical> isDefault()` Return true if this is the default object of this class.

`<type(varying_string) > mangleDirectory()` Return the directory containing MANGLE files for this survey geometry.

`<type(varying_string)(:) > mangleFiles()` Return array of MANGLE filenames for this survey geometry.

`type(varying_string) objectType()` Return the type of the object.

logical pointIncluded(\textcolor{red}{\textless double precision\textgreater} point\argin,\textcolor{re
double precision\textgreater} mass\argin) Return true if the given Cartesian point lies within the survey bounds for the given mass limit.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

double precision solidAngle(\textcolor{red}{\textless integer\textgreater} field\argin) Return the solid angle (in steradians) of the survey.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision volumeMaximum(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless integer\textgreater} field\argin) Returns the maximum volume (in Mpc^3) at which a galaxy of the specified mass (in $M_\odot$) could be detected.

logical windowFunctionAvailable() Returns true if survey 3-D window functions are available.

void windowFunctions(\textcolor{red}{\textless double precision\textgreater} mass1\argin,\textcolor{red
double precision\textgreater} mass2\argin,\textcolor{red}{\textless integer\textgreater} gridCount\argin,\textcolor{red}{\textless double precision\textgreater} boxLength\argout,\textcolor
complex((c_double_complex))\textgreater} windowFunction1\argout,\textcolor{red}{\textless complex((c_double_complex))\textgreater} windowFunction2\argout) Returns the window functions on a grid of the specified size (gridCount cells in each dimension) for galaxies of the specified mass1 and mass2 (in $M_\odot$). The boxLength should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions.

table

void deepCopyActions() Perform actions needed for deep copy of this object.

<void> destroy() Destroy the table.

void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-
Restore the state of this object from file.

void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)
Store the state of this object to file.

table1D

void deepCopyActions() Perform actions needed for deep copy of this object.

<void> destroy() Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-`
Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)`
Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table1DGeneric

`<void> create(<double(:)> x,<integer> [tableCount])` Create the object with the specified `x` values, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-`
Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)`
Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table1DLinearCSpline

`<void> create(<double> xMinimum,<double> xMaximum,<integer>xCount,<integer>[tableCount])`
Create the object with x-values spanning the range `xMinimum` to `xMaximum` in `xCount` steps, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table1DLinearLinear

`<void> create(<double> xMinimum,<double> xMaximum,<integer>xCount,<integer>[tableCount])` Create the object with x-values spanning the range `xMinimum` to `xMaximum` in `xCount` steps, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table1DLinearMonotoneCSpline

`<void> create(<double> xMinimum,<double> xMaximum,<integer>xCount,<integer>[tableCount])` Create the object with x-values spanning the range `xMinimum` to `xMaximum` in `xCount` steps, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table1DLogarithmicCSpline

`<void> create(<double> xMinimum,<double> xMaximum,<integer>xCount,<integer>[tableCount])` Create the object with x-values spanning the range `xMinimum` to `xMaximum` in `xCount` steps, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table]) Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the direction argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional allowEqual argument. If table is specified then the tableth table is used for the y-values, otherwise the first table is used.

<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table]) Populate the tableth table with elements y. If y is a scalar, then the index, i, of the element to set must also be specified.

<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise]) Reverse the table (i.e. swap x and y components) and return in reversedSelf. If table is specified then the tableth table is used for the y-values, otherwise the first table is used. If the optional precise argument is set to true then the reversal must be precisely invertible—if this is not possible the method will abort.

<integer> size() Return the size (i.e. number of x-values) in the table.

void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID- Restore the state of this object from file.

void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→) Store the state of this object to file.

<double> x(<integer> i) Return the ith x-value.

<double> xEffective(<double> x) Return the effective value of x to use in table interpolations.

<double(:)> xs(<integer> i) Return an array of all x-values.

<double> y(<integer> i,<integer> [table]) Return the ith y-value. If table is specified then the tableth table is used for the y-values, otherwise the first table is used.

<double(:)> ys(<integer> i,<integer> [table]) Return an array of all y-values. If table is specified then the tableth table is used for the y-values, otherwise the first table is used.

table1DLogarithmicLinear

<void> create(<double> xMinimum,<double> xMaximum,<integer>xCount,<integer>[tableCount]) Create the object with x-values spanning the range xMinimum to xMaximum in xCount steps, and with tableCount tables.

void deepCopyActions() Perform actions needed for deep copy of this object.

<void> destroy() Destroy the table.

<double(:)> integrationWeights(<double> x0→, <double> x1→) Return the weights to be applied to the table to integrate (using the trapezium rule) between x0 and x1.

<double> interpolate(<double> x,<integer> [table]) Interpolate to x in the tableth table.

<double> interpolateGradient(<double> x,<integer> [table]) Interpolate the gradient to x in the tableth table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table1DLogarithmicMonotoneCSpline

`<void> create(<double> xMinimum,<double> xMaximum,<integer>xCount,<integer>[tableCount])` Create the object with x-values spanning the range `xMinimum` to `xMaximum` in `xCount` steps, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double(:)> integrationWeights(<double> x0→, <double> x1→)` Return the weights to be applied to the table to integrate (using the trapezium rule) between `x0` and `x1`.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table]) Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the direction argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional allowEqual argument. If table is specified then the tableth table is used for the y-values, otherwise the first table is used.

<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table]) Populate the tableth table with elements y. If y is a scalar, then the index, i, of the element to set must also be specified.

<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise]) Reverse the table (i.e. swap x and y components) and return in reversedSelf. If table is specified then the tableth table is used for the y-values, otherwise the first table is used. If the optional precise argument is set to true then the reversal must be precisely invertible—if this is not possible the method will abort.

<integer> size() Return the size (i.e. number of x-values) in the table.

void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID- Restore the state of this object from file.

void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→) Store the state of this object to file.

<double> x(<integer> i) Return the ith x-value.

<double> xEffective(<double> x) Return the effective value of x to use in table interpolations.

<double(:)> xs(<integer> i) Return an array of all x-values.

<double> y(<integer> i,<integer> [table]) Return the ith y-value. If table is specified then the tableth table is used for the y-values, otherwise the first table is used.

<double(:)> ys(<integer> i,<integer> [table]) Return an array of all y-values. If table is specified then the tableth table is used for the y-values, otherwise the first table is used.

table1DNonUniformLinearLogarithmic

<void> create(<double(:)> x,<integer> [tableCount]) Create the object with the specified x values, and with tableCount tables.

void deepCopyActions() Perform actions needed for deep copy of this object.

<void> destroy() Destroy the table.

<double(:)> integrationWeights(<double> x0→, <double> x1→) Return the weights to be applied to the table to integrate (using the trapezium rule) between x0 and x1.

<double> interpolate(<double> x,<integer> [table]) Interpolate to x in the tableth table.

<double> interpolateGradient(<double> x,<integer> [table]) Interpolate the gradient to x in the tableth table.

`<logical> isMonotonic(<enumeration> [directionDecreasing|directionIncreasing],<logical> [allowEqual],<integer> [table])` Return true if the table y-values are monotonic. Optionally, the direction of monotonicity can be specified via the `direction` argument—by default either direction is allowed. By default consecutive equal values are considered non-monotonic. This behavior can be changed via the optional `allowEqual` argument. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<void> populate(<double>|<double(:)> y,<integer> [i],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<void> reverse(<type(table)> reversedSelf,<integer> [table], <logical> [precise])` Reverse the table (i.e. swap x and y components) and return in `reversedSelf`. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used. If the optional `precise` argument is set to `true` then the reversal must be precisely invertible—if this is not possible the method will abort.

`<integer> size()` Return the size (i.e. number of x-values) in the table.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double> xEffective(<double> x)` Return the effective value of x to use in table interpolations.

`<double(:)> xs(<integer> i)` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys(<integer> i,<integer> [table])` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

table2DLinLinLin

`<void> create(<double(:)> x,<double(:)> y,<integer> [tableCount])` Create the object with the specified `x` and `y` values, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double> interpolate(<double> x,<double> y,<integer> [table])` Interpolate to `x`, `y` in the `table`$^{\text{th}}$ table.

`<void> populate(<double>|<double(:,:)> z,<integer> [i],<integer> [j],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the indices, `i`, `j`, of the element to set must also be specified.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double(:)> xs()` Return an array of all `x` values.

`<double(:)> ys()` Return an array of all `y` values.

`<double(:,:,:)> zs()` Return an array of all `z` values.

table2DLogLogLin

`<void> create(<double> xMinimum,<double> xMaximum,<double> yMinimum,<double> yMaximum,<integer>yCount,<` Create the object with x-values spanning the range `xMinimum` to `xMaximum` in `xCount` steps, and with `tableCount` tables.

`void deepCopyActions()` Perform actions needed for deep copy of this object.

`<void> destroy()` Destroy the table.

`<double> interpolate(<double> x,<integer> [table])` Interpolate to `x` in the `table`$^{\text{th}}$ table.

`<double> interpolateGradient(<double> x,<integer> [table])` Interpolate the gradient to `x` in the `table`$^{\text{th}}$ table.

`<void> interpolationFactors(<double> x, <double> y)` Compute and store interpolation factors to `(x,y)`.

`<logical> isInitialized()` Return true if the table is initialized (this means the table is created, it may not yet have been populated).

`<void> populate(<double>|<double(:,:)> z,<integer> [i],<integer> [j],<integer> [table])` Populate the `table`$^{\text{th}}$ table with elements `y`. If `y` is a scalar, then the index, `i`, of the element to set must also be specified.

`<integer> size(<integer> dim)` Return the size (i.e. number of x or y-values) in the table of the given dimension.

`void stateRestore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID-` Restore the state of this object from file.

`void stateStore(<integer> stateFile→,<type((fgsl_file))> fgslStateFile→,<integer> stateOperationID→)` Store the state of this object to file.

`<double> x(<integer> i)` Return the `i`$^{\text{th}}$ x-value.

`<double(:)> xs()` Return an array of all x-values.

`<double> y(<integer> i,<integer> [table])` Return the `i`$^{\text{th}}$ y-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double(:)> ys()` Return an array of all y-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the y-values, otherwise the first table is used.

`<double> z(<integer> i,<integer> j,<integer> [table])` Return the `(i,j)`$^{\text{th}}$ z-value. If `table` is specified then the `table`$^{\text{th}}$ table is used for the z-values, otherwise the first table is used.

`<double(:,:)> zs(<integer> [table])` Return an array of all z-values. If `table` is specified then the `table`$^{\text{th}}$ table is used for the z-values, otherwise the first table is used.

taskAGNSpectraHopkins2008BuildFile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

logical requiresOutputFile() Should return true if the task requires the main output file to be open.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

taskBuildToolFSPS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void perform(\textcolor{red}{\textless integer\textgreater} status\argout)` Perform the task.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

taskBuildToolRecFast

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void perform(\textcolor{red}{\textless integer\textgreater} status\argout)` Perform the task.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

taskCatalogProjectedCorrelationFunction

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

taskClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

taskConditionalMassFunction

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void perform(\textcolor{red}{\textless integer\textgreater} status\argout)` Perform the task.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

taskEvolveForests

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

logical requiresOutputFile() Should return true if the task requires the main output file to be open.

<void> resumeTree(<type(mergerTree)> tree←) Restore a suspended tree.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

<void> suspendTree(<type(mergerTree)> tree←) Suspend a tree (to memory or to file).

taskExcursionSets

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

logical requiresOutputFile() Should return true if the task requires the main output file to be open.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

taskNBodyAnalyze

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

logical requiresOutputFile() Should return true if the task requires the main output file to be open.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

taskPosteriorSample

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void perform(\textcolor{red}{\textless integer\textgreater} status\argout)` Perform the task.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

taskPowerSpectra

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

logical requiresOutputFile() Should return true if the task requires the main output file to be open.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

taskReport

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((taskClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void perform(\textcolor{red}{\textless integer\textgreater} status\argout) Perform the task.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`logical requiresOutputFile()` Should return true if the task requires the main output file to be open.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

tensorRank2Dimension3Symmetric

`<type(tensorRank2Dimension3Symmetric)> add(<type(tensorRank2Dimension3Symmetric)> tensorRank2Dimension3` Add two tensors.

`<void> builder(<*type(node)> tensorRank2Dimension3SymmetricDefinition→)` Build tensor object from a provided XML description.

`<double> contract()` Contract a tensor, returning $\mathbf{T}_i^i$.

`<void> deserialize(<double(:)> tensorArray→)` Deserialize the tensor object from an array.

`<void> destroy()` Destroy a tensor object.

`<type(tensorRank2Dimension3Symmetric)> divide(<double> divisor→)` Divide a tensor by a scalar.

`<double> doubleContract(<type(tensorRank2Dimension3Symmetric)> tensor1)` Return the double contraction of two tensors, $\mathbf{A}_j^i\mathbf{B}_i^j$.

`<void> dump()` Dump the tensor object.

`<void> dumpRaw(<integer> fileHandle→)` Dump the tensor object to binary.

`<logical> equality(<type(tensorRank2Dimension3Symmetric)> self→, <double(3,3)> matrix→)` Return true if a tensor and a matrix are equal.

`<type(tensorRank2Dimension3Symmetric)> fromMatrix(double(3,3) matrix)` Construct a matrix from a tensor object.

`<void> increment(<type(tensorRank2Dimension3Symmetric)> addTensor→)` Increment the tensor object.

`<logical> isZero()` Return true if a tensor object is zero.

`<type(tensorRank2Dimension3Symmetric)> multiply(<double> multiplier→)` Multiply a tensor by a scalar.

`<integer(c_size_t) > nonStaticSizeOf()` Returns the size of any non-static components of the type.

`<void> readRaw(<integer> fileHandle→)` Read the tensor object from binary.

`<void> reset()` Reset elements to zero.

`<void> serialize(<double(:)> tensorArray←)` Serialize the tensor object to an array.

`<integer> serializeCount()` Return a count of the number of properties in a serialized tensor object.

<void> setToIdentity() Set a tensor object to the indentity (i.e. all diagonal elements 1, all other elements 0).

<void> setToUnity() Set all elements of the tensor object to unity.

<type(tensorRank2Dimension3Symmetric)> subtract(<type(tensorRank2Dimension3Symmetric)> tensor1→, <type(tensorRank2Dimension3Symmetric)> tensor2→) Subtract one tensor from another.

double(3,3) toMatrix() Construct a matrix from a tensor object.

tidalStrippingDisksClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((tidalStrippingDisksClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the disk component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

tidalStrippingDisksNull

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((tidalStrippingDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the disk component of `node`.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

tidalStrippingDisksSimple

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((tidalStrippingDisksClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the disk component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

tidalStrippingSpheroidsClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((tidalStrippingSpheroidsClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout)
Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the spheroid component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

tidalStrippingSpheroidsNull

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((tidalStrippingSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the spheroid component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

tidalStrippingSpheroidsSimple

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((tidalStrippingSpheroidsClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

double precision rateMassLoss(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout) Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the spheroid component of node.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

transferFunctionAccelerator

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou
Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

`double precision epochTime()` Return the cosmic time corresponding to the epoch for which this transfer function is defined.

`double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout)` Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative of the transfer function for $k =$`wavenumber` [Mpc^{-1}].

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the transfer function for $k =$`wavenumber` [Mpc^{-1}].

transferFunctionBBKS

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision epochTime()` Return the cosmic time corresponding to the epoch for which this transfer function is defined.

`double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout)` Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative of the transfer function for $k =$`wavenumber` [Mpc^{-1}].

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the transfer function for $k =$`wavenumber` [Mpc^{-1}].

transferFunctionBBKSWDM

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision epochTime()` Return the cosmic time corresponding to the epoch for which this transfer function is defined.

`double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout)` Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative of the transfer function for $k =$wavenumber [Mpc^{-1}].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the transfer function for $k =$wavenumber [Mpc^{-1}].

transferFunctionBode2001

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision epochTime() Return the cosmic time corresponding to the epoch for which this transfer function is defined.

double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout) Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

`double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the logarithmic derivative of the transfer function for $k =$`wavenumber` [Mpc^{-1}].

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the transfer function for $k =$`wavenumber` [Mpc^{-1}].

transferFunctionCAMB

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void checkRange(<double>wavenumber→)` Check that the provided wavenumber is within the tabulated range of the transfer function.

`void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`double precision epochTime()` Return the cosmic time corresponding to the epoch for which this transfer function is defined.

`double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout)` Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative of the transfer function for $k =$wavenumber [Mpc^{-1}].

type(varying_string) objectType() Return the type of the object.

void readFile(<char(len=*)> fileName→) Read the named transfer function file.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the transfer function for $k =$wavenumber [Mpc^{-1}].

transferFunctionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision epochTime() Return the cosmic time corresponding to the epoch for which this transfer function is defined.

double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout) Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative of the transfer function for $k =$wavenumber [Mpc^{-1}].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the transfer function for $k =$wavenumber [Mpc^{-1}].

transferFunctionEisensteinHu1999

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

<void> computeFactors(<double> wavenumber→, <double> wavenumberEffective←, <double> wavenumberNeutrir <double> L←, <double> C←) Compute common factors needed by Eisenstein and Hu [1999] transfer function calculations.

void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision epochTime() Return the cosmic time corresponding to the epoch for which this transfer function is defined.

double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout) Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative of the transfer function for $k =$wavenumber [Mpc^{-1}].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the transfer function for $k =$wavenumber [Mpc^{-1}].

transferFunctionFile

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision epochTime() Return the cosmic time corresponding to the epoch for which this transfer function is defined.

double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout) Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative of the transfer function for $k =$wavenumber [Mpc^{-1}].

type(varying_string) objectType() Return the type of the object.

void readFile(<char(len=*)> fileName→) Read the named transfer function file.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the transfer function for $k =$wavenumber [Mpc^{-1}].

transferFunctionIdentity

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((transferFunctionClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision epochTime() Return the cosmic time corresponding to the epoch for which this transfer function is defined.

double precision halfModeMass(\textcolor{red}{\textless integer\textgreater} status\argout) Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

double precision logarithmicDerivative(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin) Return the logarithmic derivative of the transfer function for $k =$wavenumber [Mpc^{-1}].

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision value(\textcolor{red}{\textless double precision\textgreater} wavenumber\argin)` Return the transfer function for $k =$`wavenumber` [Mpc^{-1}].

treeNode

`<class(nodeComponentAgeStatistics), pointer => component> ageStatistics(<integer> [instance]→, <logical> [autoCreate]→)` Return a `ageStatistics` component member of the node. If no `instance` is specified, return the first instance. If `autoCreate` is `true` then create a single instance of the component if none exists in the node.

`<integer> ageStatisticsCount()` Returns the number of `ageStatistics` components in the node.

`<void> ageStatisticsCreate(<class(nodeComponentAgeStatistics)> [template]→)` Create the `ageStatistics` component of `self`.

`<void> ageStatisticsDestroy()` Destroy the `ageStatistics` component of `self`

`<void> ageStatisticsMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→)` Move instances of the `ageStatistics` component, from one node to another.

`<void> ageStatisticsRemove(<integer> instance→)` Remove an instance of the `ageStatistics` component from a node.

`<void> attachEvent(<*class(nodeEvent)> newEvent↔)` Attach a `nodeEvent` object to this node.

`<class(nodeComponentBasic), pointer => component> basic(<integer> [instance]→, <logical> [autoCreate]→)` Return a `basic` component member of the node. If no `instance` is specified, return the first instance. If `autoCreate` is `true` then create a single instance of the component if none exists in the node.

`<integer> basicCount()` Returns the number of `basic` components in the node.

`<void> basicCreate(<class(nodeComponentBasic)> [template]→)` Create the `basic` component of `self`.

`<void> basicDestroy()` Destroy the `basic` component of `self`

`<void> basicMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→)` Move instances of the `basic` component, from one node to another.

`<void> basicRemove(<integer> instance→)` Remove an instance of the `basic` component from a node.

`<class(nodeComponentBlackHole), pointer => component> blackHole(<integer> [instance]→, <logical> [autoCreate]→)` Return a `blackHole` component member of the node. If no `instance` is specified, return the first instance. If `autoCreate` is `true` then create a single instance of the component if none exists in the node.

<integer> blackHoleCount() Returns the number of blackHole components in the node.

<void> blackHoleCreate(<class(nodeComponentBlackHole)> [template]→) Create the blackHole component of self.

<void> blackHoleDestroy() Destroy the blackHole component of self

<void> blackHoleMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the blackHole component, from one node to another.

<void> blackHoleRemove(<integer> instance→) Remove an instance of the blackHole component from a node.

<void> componentBuilder(<*type(node)> nodeDefinition→) Build components in a treeNode object given an XML definition.

<void> copyNodeTo(<class(treeNode)> targetNode↔, <logical> [skipFormationNode]→, <logical> [skipEvent]→) Make a copy of self in targetNode.

<class(nodeComponentDarkMatterProfile), pointer => component> darkMatterProfile(<integer> [instance]→, <logical> [autoCreate]→) Return a darkMatterProfile component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> darkMatterProfileCount() Returns the number of darkMatterProfile components in the node.

<void> darkMatterProfileCreate(<class(nodeComponentDarkMatterProfile)> [template]→) Create the darkMatterProfile component of self.

<void> darkMatterProfileDestroy() Destroy the darkMatterProfile component of self

<void> darkMatterProfileMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the darkMatterProfile component, from one node to another.

<void> darkMatterProfileRemove(<integer> instance→) Remove an instance of the darkMatterProfile component from a node.

<void> deserializeRates(<double precision[:]> array→, <integer> propertyType→) Deserialize rates of evolvable properties of a node from an array.

<void> deserializeRaw(<integer> fileHandle→) Deserialize a tree node object from a raw (binary) file.

<void> deserializeValues(<double precision[:]> array→, <integer> propertyType→) Deserialize evolvable properties of a node from an array.

<void> destroy() Destroy a treeNode object.

<void> destroyBranch() Destroy a branch of a merger tree rooted at this node.

<class(nodeComponentDisk), pointer => component> disk(<integer> [instance]→, <logical> [autoCreate]→) Return a disk component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> diskCount() Returns the number of disk components in the node.

<void> diskCreate(<class(nodeComponentDisk)> [template]→) Create the disk component of self.

<void> diskDestroy() Destroy the disk component of self

<void> diskMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the disk component, from one node to another.

<void> diskRemove(<integer> instance→) Remove an instance of the disk component from a node.

<class(nodeComponentDynamicsStatistics), pointer => component> dynamicsStatistics(<integer> [instance]→, <logical> [autoCreate]→) Return a dynamicsStatistics component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> dynamicsStatisticsCount() Returns the number of dynamicsStatistics components in the node.

<void> dynamicsStatisticsCreate(<class(nodeComponentDynamicsStatistics)> [template]→) Create the dynamicsStatistics component of self.

<void> dynamicsStatisticsDestroy() Destroy the dynamicsStatistics component of self

<void> dynamicsStatisticsMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the dynamicsStatistics component, from one node to another.

<void> dynamicsStatisticsRemove(<integer> instance→) Remove an instance of the dynamicsStatistics component from a node.

<*type(treeNode)> earliestProgenitor() Return a pointer to the earliest progenitor (along the main branch) of this node.

<class(nodeComponentFormationTime), pointer => component> formationTime(<integer> [instance]→, <logical> [autoCreate]→) Return a formationTime component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> formationTimeCount() Returns the number of formationTime components in the node.

<void> formationTimeCreate(<class(nodeComponentFormationTime)> [template]→) Create the formationTime component of self.

<void> formationTimeDestroy() Destroy the formationTime component of self

<void> formationTimeMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the formationTime component, from one node to another.

<void> formationTimeRemove(<integer> instance→) Remove an instance of the formationTime component from a node.

<class(nodeComponentHostHistory), pointer => component> hostHistory(<integer> [instance]→, <logical> [autoCreate]→) Return a hostHistory component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> hostHistoryCount() Returns the number of hostHistory components in the node.

<void> hostHistoryCreate(<class(nodeComponentHostHistory)> [template]→) Create the hostHistory component of self.

<void> hostHistoryDestroy() Destroy the hostHistory component of self

<void> hostHistoryMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the hostHistory component, from one node to another.

<void> hostHistoryRemove(<integer> instance→) Remove an instance of the hostHistory component from a node.

<class(nodeComponentHotHalo), pointer => component> hotHalo(<integer> [instance]→, <logical> [autoCreate]→) Return a hotHalo component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> hotHaloCount() Returns the number of hotHalo components in the node.

<void> hotHaloCreate(<class(nodeComponentHotHalo)> [template]→) Create the hotHalo component of self.

<void> hotHaloDestroy() Destroy the hotHalo component of self

<void> hotHaloMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the hotHalo component, from one node to another.

<void> hotHaloRemove(<integer> instance→) Remove an instance of the hotHalo component from a node.

<integer(kind_int8)> index() Return the index of this node.

<void> indexSet(<integer(kind_int8)> index→) Set the index of this node.

<class(nodeComponentIndices), pointer => component> indices(<integer> [instance]→, <logical> [autoCreate]→) Return a indices component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> indicesCount() Returns the number of indices components in the node.

<void> indicesCreate(<class(nodeComponentIndices)> [template]→) Create the indices component of self.

<void> indicesDestroy() Destroy the indices component of self

<void> indicesMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the indices component, from one node to another.

<void> indicesRemove(<integer> instance→) Remove an instance of the indices component from a node.

<void> initialize(<integer(kind=kind_int8)> [index]→, <type(mergerTree)> [hostTree]→) Initialize a treeNode object.

<class(nodeComponentInterOutput), pointer => component> interOutput(<integer> [instance]→, <logical> [autoCreate]→) Return a interOutput component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> interOutputCount() Returns the number of interOutput components in the node.

<void> interOutputCreate(<class(nodeComponentInterOutput)> [template]→) Create the interOutput component of self.

<void> interOutputDestroy() Destroy the interOutput component of self

<void> interOutputMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the interOutput component, from one node to another.

<void> interOutputRemove(<integer> instance→) Remove an instance of the interOutput component from a node.

<logical> isOnMainBranch() Return true if this node is on the main branch of its tree, false otherwise.

<logical> isPrimaryProgenitor() Return true if this node is the primary progenitor of its descendent, false otherwise.

<logical> isPrimaryProgenitorOf(<integer(kind_int8)> targetNodeIndex→|<*type(treeNode)> targetNode→) Return true is this node is the primary progenitor of the specified (by index or pointer) node, false otherwise.

<logical> isProgenitorOf(<integer(kind_int8)> targetNodeIndex→|<*type(treeNode)> targetNode→) Return true is this node is a progenitor of the specified (by index or pointer) node, false otherwise.

<logical> isSatellite() Return true if this node is a satellite, false otherwise.

<*type(treeNode)> lastSatellite() Return a pointer to the last satellite in the list of satellites beloning to this node.

<double precision> mapDouble0(<integer> reduction→, <integer> [optimizeFor]→) Map a rank-0, double function over components of the node.

<void> mapVoid() Map a void function over components of the node.

<class(nodeComponentMassFlowStatistics), pointer => component> massFlowStatistics(<integer> [instance]→, <logical> [autoCreate]→) Return a massFlowStatistics component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> massFlowStatisticsCount() Returns the number of massFlowStatistics components in the node.

<void> massFlowStatisticsCreate(<class(nodeComponentMassFlowStatistics)> [template]→) Create the massFlowStatistics component of self.

<void> massFlowStatisticsDestroy() Destroy the massFlowStatistics component of self

<void> massFlowStatisticsMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the massFlowStatistics component, from one node to another.

<void> massFlowStatisticsRemove(<integer> instance→) Remove an instance of the massFlowStatistics component from a node.

<*type(treeNode)> mergesWith() Return a pointer to the node with which this node will merge.

<class(nodeComponentMergingStatistics), pointer => component> mergingStatistics(<integer> [instance]→, <logical> [autoCreate]→) Return a mergingStatistics component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> mergingStatisticsCount() Returns the number of mergingStatistics components in the node.

<void> mergingStatisticsCreate(<class(nodeComponentMergingStatistics)> [template]→) Create the mergingStatistics component of self.

<void> mergingStatisticsDestroy() Destroy the mergingStatistics component of self

<void> mergingStatisticsMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the mergingStatistics component, from one node to another.

<void> mergingStatisticsRemove(<integer> instance→) Remove an instance of the mergingStatistics component from a node.

<void> moveComponentsTo(<type(treeNode)> targetNode↔) Move components from self to targetNode.

<type(varying_string)> nameFromIndex(<integer> index→, <integer> propertyType→) Return the name of a property given its index within an array.

<class(nodeComponentNBody), pointer => component> nBody(<integer> [instance]→, <logical> [autoCreate]→) Return a nBody component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> nBodyCount() Returns the number of nBody components in the node.

<void> nBodyCreate(<class(nodeComponentNBody)> [template]→) Create the nBody component of self.

<void> nBodyDestroy() Destroy the nBody component of self

<void> nBodyMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the nBody component, from one node to another.

<void> nBodyRemove(<integer> instance→) Remove an instance of the nBody component from a node.

<void> odeStepInactivesInitialize() Initialize the inactives in components of tree node self in preparation for an ODE solver step.

<void> odeStepRatesInitialize() Initialize the rates in components of tree node self in preparation for an ODE solver step.

<void> odeStepScalesInitialize() Initialize the scales in components of tree node self in preparation for an ODE solver step.

<void> output(<integer> integerProperty↔, <integer> integerBufferCount↔, <integer(kind=kind_int8)[:,:]> integerBuffer↔, <integer> doubleProperty↔, <integer> doubleBufferCount↔, <double precision[:,:]> doubleBuffer↔, <double precision> time→, <type(multiCounter)> outputInstance→) Populate output buffers with properties to output for a treeNode.

<void> outputCount(<integer> integerPropertyCount↔, <integer> doublePropertyCount↔, <double precision> time→) Increment the count of properties to output for a treeNode.

<void> outputNames(<integer> integerProperty↔, <character(len=*)[:]> integerPropertyNames↔, <character(len=*)[:]> integerPropertyComments↔, <double precision[:]> integerPropertyUnitsSI↔, <integer> doubleProperty↔, <character(len=*)[:]> doublePropertyNames↔, <character(len=*)[:]> doublePropertyComments↔, <double precision[:]> doublePropertyUnitsSI↔, <double precision> time→) Establish the names of properties to output for a treeNode.

<class(nodeComponentPosition), pointer => component> position(<integer> [instance]→, <logical> [autoCreate]→) Return a position component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> positionCount() Returns the number of position components in the node.

<void> positionCreate(<class(nodeComponentPosition)> [template]→) Create the position component of self.

<void> positionDestroy() Destroy the position component of self

<void> positionMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the position component, from one node to another.

<void> positionRemove(<integer> instance→) Remove an instance of the position component from a node.

<void> postOutput(<double precision> time→) Perform post-output processing of a treeNode.

<void> removeFromHost() Remove this node from the satellite population of its host halo.

<void> removeFromMergee() Remove this node from the list of mergees associated with its merge target.

<void> removePairedEvent(<class(nodeEvent)> event→) Remove a paired nodeEvent from this node.

<class(nodeComponentSatellite), pointer => component> satellite(<integer> [instance]→, <logical> [autoCreate]→) Return a satellite component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> satelliteCount() Returns the number of satellite components in the node.

<void> satelliteCreate(<class(nodeComponentSatellite)> [template]→) Create the satellite component of self.

<void> satelliteDestroy() Destroy the satellite component of self

<void> satelliteMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the satellite component, from one node to another.

<void> satelliteRemove(<integer> instance→) Remove an instance of the satellite component from a node.

<void> serializationOffsets(<integer> propertyType→) Compute offsets into serialization arrays for treeNode object.

<void> serializeASCII() Serialize node content to ASCII.

<integer> serializeCount(<integer> propertyType→) Return a count of the size of the node when serialized to an array.

<void> serializeInactives(<logical[:]> array←) Serialize inactive statuses of evolvable properties of a node into an array.

<void> serializeRates(<double precision[:]> array←, <integer> propertyType→) Serialize rates of evolvable properties of a node into an array.

<void> serializeRaw(<integer> fileHandle→) Serialize all content of a tree node to a raw (binary) file.

<void> serializeScales(<double precision[:]> array←, <integer> propertyType→) Serialize scales of evolvable properties of a node into an array.

<void> serializeValues(<double precision[:]> array←, <integer> propertyType→) Serialize evolvable properties of a node into an array.

<void> serializeXML(<integer> fileHandle→) Serialize tree node content as XML.

<integer(c_size_t)> sizeOf() Compute the size (in bytes) of the tree node.

<class(nodeComponentSpheroid), pointer => component> spheroid(<integer> [instance]→, <logical> [autoCreate]→) Return a spheroid component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> spheroidCount() Returns the number of spheroid components in the node.

<void> spheroidCreate(<class(nodeComponentSpheroid)> [template]→) Create the spheroid component of self.

<void> spheroidDestroy() Destroy the spheroid component of self

<void> spheroidMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the spheroid component, from one node to another.

<void> spheroidRemove(<integer> instance→) Remove an instance of the spheroid component from a node.

<class(nodeComponentSpin), pointer => component> spin(<integer> [instance]→, <logical> [autoCreate]→) Return a spin component member of the node. If no instance is specified, return the first instance. If autoCreate is true then create a single instance of the component if none exists in the node.

<integer> spinCount() Returns the number of spin components in the node.

<void> spinCreate(<class(nodeComponentSpin)> [template]→) Create the spin component of self.

<void> spinDestroy() Destroy the spin component of self

<void> spinMove(<type(treeNode)> targetNode↔, <logical> [overwrite]→) Move instances of the spin component, from one node to another.

<void> spinRemove(<integer> instance→) Remove an instance of the spin component from a node.

<double> timeStep() Return the time-step last used by this node.

<void> timeStepSet(<double>index→) Set the time-step used by this node.

<type(varying_string)> type() Return the type of this node.

<integer(kind_int8)> uniqueID() Return the unique identifier for this node.

<void> uniqueIDSet(<integer(kind_int8)> uniqueID→) Set the unique identifier for this node.

<void> walkBranchWithSatellites(<*type(treeNode)> startNode↔) Return a pointer to the next node when performing a walk of a single branch of the tree, including satellites.

<void> walkTreeWithSatellites() Return a pointer to the next node when performing a walk of the entire tree, including satellites.

unevolvedSubhaloMassFunctionClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((unevolvedSubhaloMassFunctionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\texto double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} massHost\argin) Return the differential unevolved subhalo mass function per halo for mass $[M_\odot]$ subhalos in massHost $[M_\odot]$ hosts at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless double precision\textgreater} massHost\argin) Return the unevolved subhalo mass function per host at time [Gyr] in hosts of mass massHost $[M_\odot]$ integrated between massLow and massHigh $[M_\odot]$.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

unevolvedSubhaloMassFunctionGiocoli2008

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((unevolvedSubhaloMassFunctionClass))\textgreater} destination\arginout) Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

double precision differential(\textcolor{red}{\textless double precision\textgreater} time\argin,\textc double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} massHost\argin) Return the differential unevolved subhalo mass function per halo for mass $[M_\odot]$ subhalos in massHost $[M_\odot]$ hosts at time [Gyr].

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

double precision integrated(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcol double precision\textgreater} massLow\argin,\textcolor{red}{\textless double precision\textgreater} massHigh\argin,\textcolor{red}{\textless double precision\textgreater} massHost\argin) Return the unevolved subhalo mass function per host at time [Gyr] in hosts of mass massHost $[M_\odot]$ integrated between massLow and massHigh $[M_\odot]$.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

universe

`<*type(universeEvent)> createEvent()` Create a `treeEvent` object in this universe.

`<*type(mergerTree)> popTree()` Pop a `mergerTree` from this universe.

`<void> pushTree(<*type(mergerTree)> thisTree→)` Pop a `mergerTree` from this universe.

`<void> removeEvent(<type(universeEvent)> event→)` Remove a `treeEvent` from this universe.

universeOperatorClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((universeOperatorClass))\textgreater} destination\arginou` Perform a deep copy of the object.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`type(varying_string) objectType()` Return the type of the object.

`void operate(\textcolor{red}{\textless type((universe))\textgreater} universe_\arginout)` Operate on the universe.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

universeOperatorIdentity

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((universeOperatorClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void operate(\textcolor{red}{\textless type((universe))\textgreater} universe_\arginout) Operate on the universe.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

universeOperatorIntergalacticMediumStateEvolve

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((universeOperatorClass))\textgreater} destination\arginou Perform a deep copy of the object.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

void operate(\textcolor{red}{\textless type((universe))\textgreater} universe_\arginout)
Operate on the universe.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateSet(<integer(c_size_t) > iNow→) Set the state of the IGM state class up to the given time index.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

vector

<type(vector)> add(<class(vector)> vector1→, <class(vector)> vector2→) Compute vector1+vector2.

<type(vector)> subtract(<class(vector)> vector1→, <class(vector)> vector2→) Compute vector1-vector2.

virialDensityContrastBryanNorman1998

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater}
destination\arginout) Perform a deep copy of the object.

double precision densityContrast(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing\argin) Returns the virial density contrast at the given epoch.

double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater}
mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text
double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater}
collapsing\argin) Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastClass

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastFixed

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastFriendsOfFriends

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastKitayamaSuto1996

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastPercolation

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`<void> tabulate(<double> mass→, <double> time→)` Tabulate the virial density contrast as a function of mass and time.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastSphericalCollapseMatterDE

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void retabulate(<double> time→)` Tabulate spherical collapse virial density contrast.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialDensityContrastSphericalCollapseMatterLambda

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialDensityContrastClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`double precision densityContrast(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the virial density contrast at the given epoch.

`double precision densityContrastRateOfChange(\textcolor{red}{\textless double precision\textgreater} mass\argin,\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\text double precision\textgreater} expansionFactor\argin,\textcolor{red}{\textless logical\textgreater} collapsing\argin)` Returns the rate of change of virial density contrast at the given epoch.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

`<logical> isDefault()` Return true if this is the default object of this class.

`logical isMassDependent()` Returns true if the virial density contrast is mass-dependent.

`type(varying_string) objectType()` Return the type of the object.

`<integer> referenceCountDecrement()` Decrement the reference count to this object and return the new reference count.

`<void> referenceCountIncrement()` Increment the reference count to this object.

`<void> referenceCountReset()` Reset the reference count to this object to 0.

`void retabulate(<double> time→)` Tabulate spherical collapse virial density contrast.

`void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Restore the state of this object from file.

`void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin)` Store the state of this object to file.

`double precision turnAroundOverVirialRadii(\textcolor{red}{\textless double precision\textgreater} time\argin,\textcolor{red}{\textless double precision\textgreater} expansionFactor\argin,\textcolor logical\textgreater} collapsing\argin)` Returns the ratio of turnaround and virial radii at the given epoch.

virialOrbitBenson2005

`void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin)` Return a list of parameter names allowed for this object.

`void autoHook()` Insert any event hooks required by this object.

`void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout)` Perform a deep copy of the object.

`class(virialDensityContrastClass) densityContrastDefinition()` Returns a `virialDensityContrast` object describing the virial density contrast used to define this orbit class.

`void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin)` Return an input parameter list descriptor which could be used to recreate this object.

`type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges` Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater} acceptUnboundOrbits\argin) Returns an orbit object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\ node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the square root of the mean of the squared total velocity averaged over all orbits.

virialOrbitClass

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this orbit class.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater} acceptUnboundOrbits\argin) Returns an orbit object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\ node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the square root of the mean of the squared total velocity averaged over all orbits.

virialOrbitFixed

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this orbit class.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater} acceptUnboundOrbits\argin) Returns an orbit object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\ node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the square root of the mean of the squared total velocity averaged over all orbits.

virialOrbitIsotropic

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this orbit class.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater} acceptUnboundOrbits\argin) Returns an orbit object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\ node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the square root of the mean of the squared total velocity averaged over all orbits.

virialOrbitJiang2014

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this orbit class.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater} acceptUnboundOrbits\argin) Returns an orbit object.

<void> parametersSelect(<double> massHost→, <double> massSatellite→, <integer> i←, <integer> j←) Select the parameter set to use for this satellite/host pairing.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_- size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\ node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout) Returns the square root of the mean of the squared total velocity averaged over all orbits.

virialOrbitSpinCorrelated

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\ character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout) Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this orbit class.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo
type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater}
acceptUnboundOrbits\argin) Returns an orbit object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater
node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout)
Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\
node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout)
Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout)
Returns the square root of the mean of the squared total velocity averaged over all orbits.

virialOrbitWetzel2010

void allowedParameters(\textcolor{red}{\textless type((varying_string))\textgreater} allowedParameters\
character((len=*))\textgreater} sourceName\argin) Return a list of parameter names allowed for this object.

void autoHook() Insert any event hooks required by this object.

void deepCopy(\textcolor{red}{\textless class((virialOrbitClass))\textgreater} destination\arginout)
Perform a deep copy of the object.

class(virialDensityContrastClass) densityContrastDefinition() Returns a virialDensityContrast object describing the virial density contrast used to define this orbit class.

void descriptor(\textcolor{red}{\textless type((inputParameters))\textgreater} descriptor\arginout,\tex
logical\textgreater} includeMethod\argin) Return an input parameter list descriptor which could be used to recreate this object.

type(varying_string) hashedDescriptor(\textcolor{red}{\textless logical\textgreater} includeSourceDiges
Return a hash of the descriptor for this object, optionally include the source code digest in the hash.

<logical> isDefault() Return true if this is the default object of this class.

type(varying_string) objectType() Return the type of the object.

type(keplerOrbit) orbit(\textcolor{red}{\textless type((treeNode))\textgreater} node\arginout,\textcolo
type((treeNode))\textgreater} host\arginout,\textcolor{red}{\textless logical\textgreater}
acceptUnboundOrbits\argin) Returns an orbit object.

<integer> referenceCountDecrement() Decrement the reference count to this object and return the new reference count.

<void> referenceCountIncrement() Increment the reference count to this object.

<void> referenceCountReset() Reset the reference count to this object to 0.

void stateRestore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textl
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Restore the state of this object from file.

void stateStore(\textcolor{red}{\textless integer\textgreater} stateFile\argin,\textcolor{red}{\textles
type((fgsl_file))\textgreater} fgslStateFile\argin,\textcolor{red}{\textless integer((c_-
size_t))\textgreater} stateOperationID\argin) Store the state of this object to file.

double precision velocityTangentialMagnitudeMean(\textcolor{red}{\textless type((treeNode))\textgreater
node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout)
Returns the mean of the magnitude of tangential velocity averaged over all orbits.

double precision, dimension(3) velocityTangentialVectorMean(\textcolor{red}{\textless type((treeNode))\
node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout)
Returns the mean vector of the vector tangential velocity averaged over all orbits.

double precision velocityTotalRootMeanSquared(\textcolor{red}{\textless type((treeNode))\textgreater}
node\arginout,\textcolor{red}{\textless type((treeNode))\textgreater} host\arginout)
Returns the square root of the mean of the squared total velocity averaged over all orbits.

window

<logical> pointIncluded(<double(3)> point→) Return true if the given point lives inside the MANGLE window.

<void> read(<character(len=*)> fileName→) Read the specified MANGLE polygon file.

16. Adding New Methods

16.1. Code Directives

Galacticus is designed to be flexible and extensible, allowing you to add new methods and functionality without having to hack the code extensively. To achieve this it makes much use of embedded code directives which, for example, explain to the build system how a particular subroutine or function connects into the Galacticus code. Such code directives are indicated by lines beginning with `!#`, and take the form of short blocks of XML. For example, a typical code directive might look like:

```
!# <accretionDisksMethod>
!#  <unitName>Accretion_Disks_Shakura_Sunyaev_Initialize</unitName>
!# </accretionDisksMethod>
```

This directive would typically appear just prior to a subroutine which initializes the Shakura-Sunyaev accretion disk module (it could appear anywhere throughout that module, but it makes sense to keep it close to the subroutine that it references). The `accretionDisksMethod` tag explains to the Galacticus build system that this module contains an implementation of black hole accretion disks. The `unitName` tag specifies the name of a program unit which (in this case) should be called to initialize this accretion disk implementation. The build system will then insert appropriate `use` and `call` statements into the Galacticus code such that this routine will be called if and when accretion disks are required by Galacticus.

16.2. Identifying Components and Mass Types

Many functions can be applied to different components or groups of components and to different types of mass within a node. In general, these functions make use of a set of label defined in the `Galactic_Structure_Options` module. Components are identified by a `componentType` label which can take on the following values:

`componentTypeAll` All components are matched;

`componentTypeDisk` Only disk components are matched;

`componentTypeSpheroid` Only spheroid components are matched.

`componentTypeBlackHole` Only black hole components are matched.

`componentTypeHotHalo` Only hot halo components are matched.

`componentTypeDarkHalo` Only dark matter halo components are matched.

Types of mass are identified by a `massType` which can take one of the following values:

`massTypeAll` All mass is included;

`massTypeDark` Only dark matter is included;

`massTypeBaryonic` Only baryonic mass is included;

`massTypeGalactic` Only galactic mass is included.

`massTypeGaseous` Only gaseous mass is included.

`massTypeStellar` Only stellar mass is included.

`massTypeBlackHole` Only black hole mass is included.

16.3. Components

This section describes the internal structure of node components, and how a component is implemented.

16.3.1. Component Structure

Each node in the merger tree consists of an arbitrary number of "components", each of which can actually be an array, allowing multiple components of a given class. Each component represents a specific class of object, which could be a dark matter halo, a galactic disk or a black hole etc. A component of each class may be of one or more differnt implementations of that component class. Component classes are extensions of the `nodeComponent` base class, while each implementation is an extension of its component class (or, sometimes, of another implementation of that same class). Each component implementation type consists of a set of data[1], representing the properties (mass, size etc.) of the component, along with the rates of change (and ODE solver tolerances) for any properties which are evolvable. Additionally, each component contains a large number of methods (functions) which can be used to access its properties, query its interfaces and which are used internally to perform ODE evolution, output etc. The `nodeComponent` base class and all classes derived from it are built automatically by `Galacticus::Build::Components` at compile time (take a look in `work/build/objects.nodes.components.Inc` if you want to see the generated code).

16.3.2. Extending Components

It is possible to create a component which extends an existing component (see the discussion of the `extends` element in §16.3.3). This capability is intended to allow new properties to be added to a component without having to create a whole new copy of the component. It is *not* intended to allow changes in the way in which the component is evolved through the halo hierarchy. (With the exception that rules to describe how the newly added properties will evolve through the halo hierarchy can be added of course.)

A simple example of this extension capability can be found in the `scaleShape` dark matter profile component (§11.13.3), which extends the `scale` dark matter profile component (§11.13.1). In this case, the `scaleShape` component adds a new property, `shape`, and specifies how it is to be initialized, evolved, output, and change by node promotion events. It *does not* affect how the `scale` property, inherited from the `scale` dark matter profile component, is evolved.

[1] Data objects in components can be real, integer, boolean or of derived type. For derived types, currently `history`, `abundances`, `chemicals`, and `keplerOrbit` are supported. Adding additional derived types is possible, providing that the type supports the required methods for output, serialization, etc. Data objects can currently be scalar or rank-1 arrays.

16.3.3. Implementing a New Component

Implementing a new component involves writing some modules and functions which contain a definition of the component and, if necessary, handle initialization, creation, evolution, and responses to any events. Frequently, the easiest way to make a new component is to copy a previously existing one and modify it as needed. Details of the various functions that component modules must perform are given below. By convention, a component's implementation is split into three or four files, although some components might not need all of these files. These files are named as follows (with `<component>` acting as a placeholder for the name of the component in question):

`objects.nodes.components.<component>.F90` The primary file which describes the component and its properties, and which contains functions that manipulate the component as it evolves through a merger tree (ODE rates, behavior during mergers, etc.);

`objects.nodes.components.<component>.bound_functions.F90` Contains functions which will be bound to the component object (i.e. the `nodeComponent<Class><Implementation>` class), and so will be available as type bound procedures. Generally, these functions will include any which get or set values of properties in the component, those which return information about its internal state (such as the density at some position in the component; see §16.4.3), and any other functions which we may want to be overridden by extensions to the component.

`objects.nodes.components.<component>.data.F90` Contains any data which may need to be shared between the above two files. This might contain parameters which control some property of the component that is the same for all instances (e.g. if spheroids are modelled as Sérsic profiles all with the same value of the Sérsic index, that value might be placed into this file).

`objects.nodes.components.<component>.structure.F90` Contains any functions which implement the structure (e.g. density, rotation curve) of the component and which cannot be placed in `objects.nodes.components.<c` `functions.Inc` due to dependencies on modules which in turn depend on the `Galacticus_Nodes` module.

In general, `objects.nodes.components.<component>.F90` is the place for the component definition and functions which process the component during tree evolution (including output), while `objects.nodes.components.<compone` `functions.Inc` is intended for functions which record or report the internal state of the component.

Component Definition

Component definition itself takes the form of an embedded XML document. The following example illustrates such a document:

```
!# <component>
!#  <class>disk</class>
!#  <name>exponential</name>
!#  <isDefault>yes</isDefault>
!#  <properties>
!#   <property>
!#     <name>isInitialized</name>
!#     <type>logical</type>
!#     <rank>0</rank>
!#     <attributes isSettable="true" isGettable="true" isEvolvable="false" />
!#   </property>
!#   <property>
!#     <name>massStellar</name>
```

```
!#     <type>real</type>
!#     <rank>0</rank>
!#     <attributes isSettable="true" isGettable="true" isEvolvable="true" />
!#     <output unitsInSI="massSolar" comment="Mass of stars in the exponential disk."/>
!#   </property>
!#   <property>
!#     <name>abundancesStellar</name>
!#     <type>abundances</type>
!#     <rank>0</rank>
!#     <attributes isSettable="true" isGettable="true" isEvolvable="true" />
!#     <output unitsInSI="massSolar" comment="Mass of metals in the stellar phase of the exponential d
!#   </property>
!#   <property>
!#     <name>massGas</name>
!#     <type>real</type>
!#     <rank>0</rank>
!#     <attributes isSettable="true" isGettable="true" isEvolvable="true" createIfNeeded="true" makeGe
!#     <output unitsInSI="massSolar" comment="Mass of gas in the exponential disk."/>
!#   </property>
!#   <property>
!#     <name>coolingMass</name>
!#     <attributes isSettable="false" isGettable="false" isEvolvable="true" isDeferred="rate" bindsTo=
!#     <type>real</type>
!#     <rank>0</rank>
!#     <isVirtual>yes</isVirtual>
!#   </property>
!#   <property>
!#     <name>halfMassRadius</name>
!#     <attributes isSettable="false" isGettable="true" isEvolvable="false" />
!#     <type>real</type>
!#     <rank>0</rank>
!#     <isVirtual>yes</isVirtual>
!#     <getFunction>Node_Component_Disk_Exponential_Half_Mass_Radius</getFunction>
!#   </property>
!#   <property>
!#     <name>luminositiesStellar</name>
!#     <type>real</type>
!#     <rank>1</rank>
!#     <attributes isSettable="true" isGettable="true" isEvolvable="true" />
!#     <classDefault modules="Stellar_Population_Properties_Luminosities" count="Stellar_Population_Lu
!#     <output labels="':'//Stellar_Population_Luminosities_Name({i})" count="Stellar_Population_Lumin
!#   </property>
!#  </properties>
!#  <bindings>
!#   <binding method="attachPipes" function="Node_Component_Disk_Exponential_Attach_Pipes" type="void'
!#  </bindings>
!#  <functions>objects.nodes.components.disk.exponential.custom_methods.inc</functions>
!# </component>
```

The elements of this document have the following meaning:

`class` *[Required]* Specifies the component class of which this is an implementation.

`name` *[Required]* Specifies the name of this specific implementation.

`extends` *[Optional]* If present, this element must contain `class` and `name` elements which specify the type of component which should be extended. The component then automatically inherits all properties and type-bound functions of the extended type.

`isDefault` *[Required]* Specifies whether or not this should be the default implementation of this class. Note that only one implementation of each class can be declared to be the default. If no implementation of a given class is declared to be the default then the (automatically generated) `null` implementation will be made the default.

`properties` *[Optional]* Contains an array of `property` elements which specify the properties of this implementation. Each member `property` has the following structure:

`name` *[Required]* The name of the property.

`type` *[Required]* The type (one of `real`, `integer`, `logical`, `history`, `abundances`, `chemicals`, or `keplerOrbit` at present) of the property.

`rank` *[Required]* The rank of this property (currently `0` for a scalar or `1` for a 1-D array).

`attributes` *[Required]* Attributes of this property:

`isSettable` If `true` then the value of this property can be set directory.

`isGettable` If `true` then the value of this property can be got directory.

`isEvolvable` If `true` this property evolves as part of the Galacticus ODE system.

`createIfNeeded` If `true` then any attempt to get, set, or adjust the rate of this property will cause the component to be created if it does not already exist. This is useful if the component should be created in response to mass transfer from some other component for example.

`makeGeneric` If `true` then any `rate` method for this property will have a version created which binds to the base `nodeComponent` class. This version is suitable for attaching to deferred rate functions of components of another class. For example, the disk gas mass rate function is made generic, and then attached to the deferred cooling rate of the hot halo using:

```
call hotHalo%hotHaloCoolingMassRateFunction(DiskExponentialMassGasRateGeneric)
```

`isDeferred` Contains a "`:`" separated list which can contain `get`, `set`, and `rate`. The methods present in this list will not have functions bound to them at compile time. Instead a function will be created which allows a function to be bound to these methods at run time. For example:

```
call myComponent%massFunction    (My_Component_Mass_Get_Function)
call myComponent%massSetFunction (My_Component_Mass_Set_Function)
call myComponent%massRateFunction(My_Component_Mass_Rate_Function)
```

Additionally, a method is created which returns true or false depending on whether the method has been attached to a function yet, e.g.

```
myComponent%massIsAttached    ()
myComponent%massSetIsAttached ()
myComponent%massRateIsAttached()
```

`bindsTo` Specifies to which level in the class hierarchy set, get and rate methods should be bound. Normally, these are bound to the component implementation itself. However, it can be useful to specify a binding of "`top`" to bind to the base `nodeComponent` class to make these methods interoperable with properties of other classes (see the discussion of the `makeGeneric` element above).

`output` *[Optional]* If present, the property will be included in the Galacticus output file. The following attributes control the details of that output:

`unitsInSI` The units of the output quantity in the SI system.

`comment` A comment to be included with the HDF5 dataset for this property.

`condition` A statement which must evaluate to `true` or `false` and which will be used to determine if the property will be output. The present output time for is available as `time`. In the case of an array property the construct "`{i}`" can be used to pass the index of the element for which the condition should be evaluated.

`modules` A comma-separated list of any modules required to perform the output (e.g. modules which contain functions or values that are used).

Additional attributes are required for array properties:

`labels` This can be an array, declared as "`[`L_1`,...,`L_N`]`", specifying the suffix to be added to the property name for each component of the array in the output, or a function which returns the suffix. In the case of a function the construct "`{i}`" can be used to pass the index of the element for which the suffix is required.

`count` A statement which evaluates the the number of elements to be output (i.e. the length of the array).

`isVirtual` *[Optional]* If present and set to "`yes`", this property is a virtual property. A virtual property has no data associated with it and must supply its own functions for getting, setting and adjusting its rate of change (if allowed by the property's attributes). Virtual properties are used for quantities which are derived from actual properties of the component implementation (for example, a star formation rate could be a virtual property if it is derived from an actual gas mass property) or for adjusting the rates of several actual properties simultaneously.

`getFunction` *[Optional]* Specifies the function to be used for getting the value of the property, overriding the default get function. The function must be included in the `Galacticus_Nodes` module by use of the `functions` element described below. Note that this function, by virtue of its priveleged access to the itnernal structure of node components, can access the value of the data associated with the propery using:

```
myComponent%<property>Data%value
```

`setFunction` *[Optional]* The same as `getFunction` but defines a function to set the value of the property.

`classDefault` *[Optional]* Specifies the default value for this property if the component class has not been created (i.e. has no specific implementation yet). The content of this element gives the default value (which can be a scalar, an array, a function, etc.). Additional, optional attributes control the use of this element:

`modules` Specifies a comma-separated list of modules which are required to set the default values (e.g. modules which contain the value or function to be used).

`count` For array properties whose size is not known at compile-time, it is possible to specify a function which will return the appropriate size of the array at run-time. The scalar default value given in the `classDefault` element will then be replicated the appropriate number of times.

`bindings` *[Optional]* Contains an array of `binding` elements which specify functions to bind to this implementation. Each member `binding` has the following structure:

- `method` The name of the bound method, such that the function can be accessed using

  ```
  myComponent%<method>(...)
  ```

- `function` The function to which the method should be bound. (This function must be included in the `Galacticus_Nodes` module by use of the `functions` element described below.
- `type` The type of function.
- `bindsTo` Specifies where this method should be bound. "`component`" specifies binding to the specific implementation of this component class, "`componentClass`" specifies binding to the component class, while "`top`" specifies binding to the base `nodeComponent` class.

`functions` *[Optional]* Contains the name of a file which will be included into the `Galacticus_Nodes` module. This file can contain functions which will be bound to this implementation. By virtue of being included in the `Galacticus_Nodes` module these functions have privelged access to the internal structure of all node component objects.

Component Initialization

Initialization of a component module (if necessary, for example, to read parameters or allocate workspace) can occur at a number of different points in the execution of Galacticus. Providing initialization occurs in advance of any calculations then any point is acceptable. One possibility is simply to call an initialization function at the head of all functions defined in the component module. This initialization function should return immediately if it has already been called (to avoid duplicate initialization). Another option is to use the `mergerTreePreTreeConstructionTask` event (see §16.4.3) to perform initialization just before merger trees are constructed (the initialization function must again return immediately if it has been previously called).

Optionally, a component may include a `mergerTreeEvolveThreadInitialize` directive, which gives the name of a subroutine in its `unitName` element. The routine specified by `mergerTreeEvolveThreadInitialize` is called by all threads prior to merger tree evolution, and can therefore be used to perform any "per thread" initialization. Note that this routine will be called many times during a given Galacticus run—it is the responsibility of the routine to ensure that it performs any initialization only once.

Component Access, Creation and Destruction

When a node is created, it initially contains no components. A component must therefore create itself on the fly as needed. Typically, a component is first created when an attempt is made to set a property value, or to adjust the rate of change of a property value or in response to some event (e.g. a satellite component may be created in response to a node merging with a larger node). Requests for property values frequently *do not* require that the component exist, as a zero value can often be returned instead[2].

To access a component from a node, use:

```
myComponent => thisNode%<class>([instance=<N>,autoCreate=<create>])
```

where `class` is the component class required, the optional `instance` argument requests a specific instance of the component (relevant if the node contains more than one of a particular component, e.g. if it contains two supermassive black holes for example; if no `instance` is specified the first instance will be returned), and the `autoCreate` option specifies whether or not the component should be automatically created (assuming it does not already exist). `autoCreate=true` should be used to create components initially.

A component of a node can be destroyed using:

[2] Or some other value if a `classDefault` has been specified (see §16.3.3).

```
call thisNode%<class>Destroy()
```

Component Methods

Component implementations optionally provide functions to get and set their properties (and to set the rate of change of evolvable properties) so that other components and functions within Galacticus to can interact with them in a way that is independent of the specific component implementation chosen. To permit this, Galacticus creates functions for each property to access it in all permitted ways. For example, the `exponential` implementation of the `disk` component class has a "`massStellar`" property defined by:

```
<method>
  <name>massStellar</name>
  <type>real</type>
  <rank>0</rank>
  <attributes isSettable="true" isGettable="true" isEvolvable="true" />
</method>
```

This causes Galacticus to define several functions bound to the `nodeComponentDisk` class:

`massStellarIsSettable` Returns `true` if this property is settable;

`massStellarIsGettable` Returns `true` if this property is gettable;

`massStellarSet` Sets the value of this property to the supplied argument;

`massStellarGet` Gets the value of this property;

`massStellarRate` Cumulates its argument to the rate of change of this property;

`massStellarScale` Sets the absolute scale for this property used in ODE error control;

along with several others used internally for output, serialization etc.

Component Evolution

All component properties which have an `isEvolvable` attribute set to `true` are included in Galacticus's ODE solver as the node is evolved forward in time. As described in §16.3.3, Galacticus will create two functions that permit the rate of change of a property adjusted and for the absolute scale used in ODE error control to be set.

A "rate compute" function should be defined to perform any calculations necessary to determine the rate of change of the property and adjust the rate appropriately. Below is an example of the rate compute subroutine for the stellar mass property of the exponential disk component, with only the basic structure shown:

```
!# <rateComputeTask>
!#  <unitName>Node_Component_Disk_Exponential_Rate_Compute</unitName>
!# </rateComputeTask>
subroutine Node_Component_Disk_Exponential_Rate_Compute(node,&
   &odeConverged,interrupt,interruptProcedure,propertyType)
  implicit none
  type     (treeNode                ), pointer , intent(inout) :: node
  logical                            , intent(in    ) :: &
     &odeConverged
```

```
    logical                                     , intent(inout) :: interrupt
    procedure(                        ), pointer, intent(inout) :: &
       &interruptProcedure
    integer                                     , intent(in    ) :: &
       &propertyType
    class     (nodeComponentDisk      ), pointer                :: disk

    ! Get the disk and check that it is of our class.
    disk => node%disk()
    select type (disk)
    class is (nodeComponentDiskExponential)
      ...
      call disk%massStellarRate(stellarMassRate)
      ...
    end select
    return
  end subroutine Node_Component_Disk_Exponential_Rate_Comput
```

Here, we get the disk component and check that it of the `exponential` variety. If it is, we compute the rates of change for one or more properties and then adjust their rates appropriately. If multiple instances of a component are used then the rate compute function should loop over all instances and adjust rates appropriately. The `propertyType` argument will be set either to `propertyTypeActive` or `propertyTypeInactive`, and indicates if rates should be computed for active or inactive variables. (Rates for active variables can be computed and set even if inactive variables are requested, and vice versa. They will simply be ignored, and so this merely wastes compute time.) The `odeConverged` variable indicates if the ODE solver has reached convergence—in some instances it is useful to trigger interrupts only once convergence is reached. If an interrupt occurs, `interrupt` should be set to `true`, and `interruptProcedure` should be set to point to the function to call on interrupt.

When evolving ODEs the ODE solver aims to keep the error on property i below

$$D_i = \epsilon_{\rm abs} s_i + \epsilon_{\rm rel} |y_i|, \tag{16.1}$$

where $epsilon_{\rm abs}$ =`[odeToleranceAbsolute]`, $epsilon_{\rm rel}$ =`[odeToleranceRelative]`, y_i is the value of property i and s_i is a scaling factor which controls the absolute tolerance for this property. By default, $s_i = 1$, but this can be changed for a component utilizing the `scaleSetTask` directive. This allows a function to be called in which the component sets suitable scale factors for each of its properties prior to any ODE evolution being carried out. This can be very useful, for example, in cases where two components are coupled. Consider a case where a disk is transferring material to a spheroid via a bar instability. If the disk is orders of magnitude more massive that the spheroid then the rate of mass transfer can be very high (i.e. $\dot{y}/y$ for the spheroid will be large). With just a relative tolerance (i.e. the $\epsilon_{\rm rel}|y_i|$ term) this would require very short timesteps for the spheroid. However, in such cases we don't care about such tiny tolerances for the spheroid (since it will grow to be substantially more massive). Therefore, it may be appropriate to set s_i to be equal to the sum of the disk and spheroid properties for example. The scale set directive and associated subroutine should follow this template:

```
!# <scaleSetTask>
!#  <unitName>Node_Component_Disk_Exponential_Scale_Set</unitName>
!# </scaleSetTask>
subroutine Node_Component_Disk_Exponential_Scale_Set(thisNode)
  implicit none
  type (treeNode         ), pointer, intent(inout) :: thisNode
```

```
    class(nodeComponentDisk), pointer                :: disk

    ! Get the disk component.
    disk => thisNode%disk()
    ! Check if an exponential disk component exists.
    select type (disk)
    class is (nodeComponentDiskExponential)
      ...
      call disk%massStellarScale(massScale)
      ...
    end select
    return
  end subroutine Node_Component_Disk_Exponential_Scale_Set
```

Sensible choices for the s_i factors can significantly speed-up execution of Galacticus.

Evolution Interrupts

It is often necessary to interrupt the smooth ODE evolution of a node in Galacticus. This can happen if, for example, a galaxy mergers with another galaxy (in which case the merger must be processed prior to further evolution) or if a component must be created before evolution can continue. The rate adjust and rate compute subroutines allow for interrupts to be flagged via their `interrupt` and `interruptProcedure` arguments. If an interrupt is required then `interrupt` should be set to true, while `interruptProcedure` should be set to point to a procedure which will handle the interrupt. Then, providing no other interrupt occurred earlier, the evolution will be stopped and the interrupt procedure called before evolution is continued.

An interrupt procedure should have the form:

```
subroutine My_Interrupt_Procedure(thisNode)
  implicit none
  type(treeNode), pointer, intent(inout) :: thisNode

  ! Do whatever needs to be done to handle the interrupt.

  return
end subroutine My_Interrupt_Procedure
```

16.4. Existing Method Types

16.4.1. Functions

Functions implement basic calculations (e.g. computing the power spectrum).

Accretion Disk Spectra

Additional implementations for accretion disk spectra are added using the `accretionDiskSpectra` class. The implementation should be placed in a file containing the directive:

```
!# <accretionDiskSpectra name="accretionDiskSpectraMyImplementation">
!# <description>A short description of the implementation.</description>
!# </accretionDiskSpectra>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `accretionDiskSpectraMyImplementation`. The file *must* define a type that extends the `accretionDiskSpectraClass` class (or extends another type which is itself an extension of the `accretionDiskSpectraClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`spectrum` Returns the spectrum (in units of $L_\odot$ Hz^{-1}) of the accretion disk at the given wavelength (in units of Å) for `node`. Must have the following interface:

```
double precision function myImplementationSpectrum(self,node,wavelength)
 class           (accretionDiskSpectraClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: wavelength
end double precision function myImplementationSpectrum
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (accretionDiskSpectraClass), intent(inout)           :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (accretionDiskSpectraClass), intent(inout)           :: self
 type   (inputParameters          ), intent(inout)           :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(accretionDiskSpectraClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionDiskSpectraClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (accretionDiskSpectraClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(accretionDiskSpectraClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(accretionDiskSpectraClass), intent(inout) :: self
 class(accretionDiskSpectraClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionDiskSpectraClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`accretionDiskSpectraHopkins2007` Accretion disk spectra using the model of Hopkins et al. [2007].

`accretionDiskSpectraFile` Accretion disk spectra are interpolated from tables read from file.

Accretion disks

Additional implementations for accretion disks are added using the `accretionDisks` class. The implementation should be placed in a file containing the directive:

```
!# <accretionDisks name="accretionDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </accretionDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all

functions required by the implementation after that line. Function names should begin with `accretionDisksMyImplementation`. The file *must* define a type that extends the `accretionDisksClass` class (or extends another type which is itself an extension of the `accretionDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (accretionDisksClass), intent(inout)           :: self
  logical                     , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (accretionDisksClass), intent(inout)           :: self
 type   (inputParameters    ), intent(inout)           :: descriptor
 logical                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(accretionDisksClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionDisksClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (accretionDisksClass)                          , intent(inout) :: self
 type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*              )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`powerJet` Returns the power of the jet launched by the accretion disk in units of $M_\odot$ $(\mathrm{km/s})^2$ Gyr^{-1}. Must have the following interface:

```
double precision function myImplementationPowerJet(self,blackHole,accretionRateMass)
 class           (accretionDisksClass   ), intent(inout) :: self
 class           (nodeComponentBlackHole), intent(inout) :: blackHole
 double precision                        , intent(in   ) :: accretionRateMass
end double precision function myImplementationPowerJet
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(accretionDisksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`efficiencyRadiative` Returns the radiative efficiency of the accretion disk. Must have the following interface:

```
double precision function myImplementationEfficiencyRadiative(self,blackHole,&
&  accretionRateMass)
 class           (accretionDisksClass   ), intent(inout) :: self
 class           (nodeComponentBlackHole), intent(inout) :: blackHole
 double precision                        , intent(in   ) :: accretionRateMass
end double precision function myImplementationEfficiencyRadiative
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(accretionDisksClass), intent(inout) :: self
 class(accretionDisksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`rateSpinUp` Returns the spin-up rate of the black hole due to accretion from the accretion disk. Must have the following interface:

```
double precision function myImplementationRateSpinUp(self,blackHole,accretionRateMass)
 class           (accretionDisksClass   ), intent(inout) :: self
 class           (nodeComponentBlackHole), intent(inout) :: blackHole
 double precision                        , intent(in   ) :: accretionRateMass
end double precision function myImplementationRateSpinUp
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionDisksClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`accretionDisksSwitched` An accretion disk class in which accretion switches between thin-disk and ADAF modes.

`accretionDisksShakuraSunyaev` A Shakura and Sunyaev [1973] accretion disk class.

`accretionDisksEddingtonLimited` An accretion disk class in which accretion is always Eddington-limited.

`accretionDisksADAF` An ADAF accretion disk class.

Accretion Onto Halos

Additional implementations for accretion onto halos are added using the `accretionHalo` class. The implementation should be placed in a file containing the directive:

```
!# <accretionHalo name="accretionHaloMyImplementation">
!# <description>A short description of the implementation.</description>
!# </accretionHalo>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `accretionHaloMyImplementation`. The file *must* define a type that extends the `accretionHaloClass` class (or extends another type which is itself an extension of the `accretionHaloClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (accretionHaloClass), intent(inout)          :: self
  logical                    , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (accretionHaloClass), intent(inout)          :: self
  type   (inputParameters   ), intent(inout)          :: descriptor
  logical                    , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(accretionHaloClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`accretionRateChemicals` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of chemicals from the IGM onto `node` in the given `accretionMode`. Must have the following interface:

```
 type(chemicalAbundances) function myImplementationAccretionRateChemicals(self,node,&
&  accretionMode)
  class  (accretionHaloClass), intent(inout) :: self
  type   (treeNode          ), intent(inout) :: node
  integer                    , intent(in   ) :: accretionMode
 end type(chemicalAbundances) function myImplementationAccretionRateChemicals
```

`accretedMassChemicals` Returns the mass of chemicals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes. Must have the following interface:

```
 type(chemicalAbundances) function myImplementationAccretedMassChemicals(self,node,&
&  accretionMode)
  class  (accretionHaloClass), intent(inout) :: self
  type   (treeNode          ), intent(inout) :: node
  integer                    , intent(in   ) :: accretionMode
 end type(chemicalAbundances) function myImplementationAccretedMassChemicals
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (accretionHaloClass), intent(inout) :: self
  integer                    , intent(in   ) :: stateFile
  type   (fgsl_file         ), intent(in   ) :: fgslStateFile
  integer(c_size_t          ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`accretionRate` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of mass from the IGM onto `node` in the given `accretionMode`. Must have the following interface:

```
 double precision function myImplementationAccretionRate(self,node,accretionMode)
  class  (accretionHaloClass), intent(inout) :: self
  type   (treeNode          ), intent(inout) :: node
  integer                    , intent(in   ) :: accretionMode
 end double precision function myImplementationAccretionRate
```

`accretedMassMetals` Returns the mass of metals (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes. Must have the following interface:

```
 type(abundances) function myImplementationAccretedMassMetals(self,node,accretionMode)
  class  (accretionHaloClass), intent(inout) :: self
  type   (treeNode          ), intent(inout) :: node
  integer                    , intent(in   ) :: accretionMode
 end type(abundances) function myImplementationAccretedMassMetals
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (accretionHaloClass)                          , intent(inout) :: self
  type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*             )                          , intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`accretionRateMetals` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of accretion of metals from the IGM onto `node` in the given `accretionMode`. Must have the following interface:

```
type(abundances) function myImplementationAccretionRateMetals(self,node,accretionMode)
 class  (accretionHaloClass), intent(inout) :: self
 type   (treeNode          ), intent(inout) :: node
 integer                    , intent(in   ) :: accretionMode
end type(abundances) function myImplementationAccretionRateMetals
```

`failedAccretedMass` Returns the mass (in units of $M_\odot$) of that failed to accrete from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes. Must have the following interface:

```
double precision function myImplementationFailedAccretedMass(self,node,accretionMode)
 class  (accretionHaloClass), intent(inout) :: self
 type   (treeNode          ), intent(inout) :: node
 integer                    , intent(in   ) :: accretionMode
end double precision function myImplementationFailedAccretedMass
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(accretionHaloClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(accretionHaloClass), intent(inout) :: self
 class(accretionHaloClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionHaloClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`failedAccretionRate` Returns the rate (in units of $M_\odot$ Gyr^{-1}) of failed accretion of mass from the IGM onto `node` in the given `accretionMode`. Must have the following interface:

```
double precision function myImplementationFailedAccretionRate(self,node,accretionMode)
 class  (accretionHaloClass), intent(inout) :: self
 type   (treeNode          ), intent(inout) :: node
 integer                    , intent(in   ) :: accretionMode
end double precision function myImplementationFailedAccretionRate
```

`accretedMass` Returns the mass (in units of $M_\odot$) of accreted from the IGM onto `node` in the given `accretionMode`. Used to initialize nodes. Must have the following interface:

```
double precision function myImplementationAccretedMass(self,node,accretionMode)
 class  (accretionHaloClass), intent(inout) :: self
 type   (treeNode          ), intent(inout) :: node
 integer                    , intent(in   ) :: accretionMode
end double precision function myImplementationAccretedMass
```

`branchHasBaryons` Returns `true` if this tree branch may accrete baryons, and `false` otherwise. Must have the following interface:

```
logical function myImplementationBranchHasBaryons(self,node)
 class(accretionHaloClass), intent(inout)         :: self
 type (treeNode          ), intent(inout), target :: node
end logical function myImplementationBranchHasBaryons
```

Existing implementations are:

`accretionHaloColdMode` Accretion onto halos using simple truncation to mimic the effects of reionization and accounting for cold mode accretion. See §12.2.3.

`accretionHaloNaozBarkana2007` Accretion onto halos using filtering mass of the IGM calculated from an equation from Naoz and Barkana [2007]. See §12.2.4.

`accretionHaloBertschinger` Accretion onto halos using simple truncation to mimic the effects of reionization, and the Bertschinger mass to define available mass.

`accretionHaloZero` Accretion onto halos assuming no accretion.

`accretionHaloSimple` Accretion onto halos using simple truncation to mimic the effects of reionization. See §12.2.1.

Halo Total Accretion Rates

Additional implementations for halo total accretion rates are added using the `accretionHaloTotal` class. The implementation should be placed in a file containing the directive:

```
!# <accretionHaloTotal name="accretionHaloTotalMyImplementation">
!# <description>A short description of the implementation.</description>
!# </accretionHaloTotal>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `accretionHaloTotalMyImplementation`. The file *must* define a type that extends the `accretionHaloTotalClass` class (or extends another type which is itself an extension of the `accretionHaloTotalClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (accretionHaloTotalClass), intent(inout)           :: self
  logical                         , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (accretionHaloTotalClass), intent(inout)           :: self
 type   (inputParameters        ), intent(inout)           :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(accretionHaloTotalClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionHaloTotalClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`accretionRate` Return the total accretion rate onto the given `node`. Must have the following interface:

```
double precision function myImplementationAccretionRate(self,node)
 class(accretionHaloTotalClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationAccretionRate
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (accretionHaloTotalClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(accretionHaloTotalClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(accretionHaloTotalClass), intent(inout) :: self
 class(accretionHaloTotalClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (accretionHaloTotalClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`accretedMass` Return the total accreted mass in the given `node`. Must have the following interface:

```
double precision function myImplementationAccretedMass(self,node)
 class(accretionHaloTotalClass), intent(inout) :: self
 type (treeNode               ), intent(inout) :: node
end double precision function myImplementationAccretedMass
```

Existing implementations are:

`accretionHaloTotalBertschinger` A halo total accretion class which assumes the accretion corresponds to the basic mass. See §12.3.2.

`accretionHaloTotalSimple` A halo total accretion class which assumes the accretion corresponds to the basic mass. See §12.3.1.

Atomic cross sections for photo-ionization.

Additional implementations for atomic cross sections for photo-ionization. are added using the `atomicCrossSectionIonizati` class. The implementation should be placed in a file containing the directive:

```
!# <atomicCrossSectionIonizationPhoto name="atomicCrossSectionIonizationPhotoMyImplementation">
!# <description>A short description of the implementation.</description>
!# </atomicCrossSectionIonizationPhoto>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `atomicCrossSectionIonizationPhotoMyImplementation`. The file *must* define a type that extends the `atomicCrossSectionIonizationPhotoClass` class (or extends another type which is itself an extension of the `atomicCrossSectionIonizationPhotoClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (atomicCrossSectionIonizationPhotoClass), intent(inout)          :: self
  logical                                        , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (atomicCrossSectionIonizationPhotoClass), intent(inout)          :: self
  type   (inputParameters                       ), intent(inout)          :: descriptor
  logical                                        , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(atomicCrossSectionIonizationPhotoClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`crossSection` Returns the cross-section for photoionization (in units of cm^2) for a given atom in a given ionization state at the specified `wavelength` (given in units of Å). Must have the following interface:

```
 double precision function myImplementationCrossSection(self,atomicNumber, &
&  ionizationState, shellNumber,wavelength)
  class           (atomicCrossSectionIonizationPhotoClass), intent(inout) :: self
  integer                                                 , intent(in   ) :: &
&  atomicNumber, ionizationState, shellNumber
  double precision                                        , intent(in   ) :: wavelength
 end double precision function myImplementationCrossSection
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (atomicCrossSectionIonizationPhotoClass), intent(inout) :: self
  integer                                        , intent(in   ) :: stateFile
  type   (fgsl_file                             ), intent(in   ) :: fgslStateFile
  integer(c_size_t                              ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (atomicCrossSectionIonizationPhotoClass)                        , intent(&
&  inout) :: self
  type     (varying_string                        ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                                 )                        , intent(&
&  in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(atomicCrossSectionIonizationPhotoClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(atomicCrossSectionIonizationPhotoClass), intent(inout) :: self
 class(atomicCrossSectionIonizationPhotoClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicCrossSectionIonizationPhotoClass), intent(inout) :: self
 integer                                        , intent(in   ) :: stateFile
 type   (fgsl_file                              ), intent(in   ) :: fgslStateFile
 integer(c_size_t                               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`atomicCrossSectionIonizationPhotoVerner` An atomic photoionization cross section class based on (`phfit2.f`) written by D. A. Verner (Version 2. March 25, 1996.

Atomic Collisional Excitation

Additional implementations for atomic collisional excitation are added using the `atomicExcitationRateCollisional` class. The implementation should be placed in a file containing the directive:

```
!# <atomicExcitationRateCollisional name="atomicExcitationRateCollisionalMyImplementation">
!# <description>A short description of the implementation.</description>
!# </atomicExcitationRateCollisional>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `atomicExcitationRateCollisionalMyImplementation`. The file *must* define a type that extends the `atomicExcitationRateCollisionalClass` class (or extends another type which is itself an extension of the `atomicExcitationRateCollisionalClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (atomicExcitationRateCollisionalClass), intent(inout)          :: self
  logical                                      , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (atomicExcitationRateCollisionalClass), intent(inout)          :: self
  type   (inputParameters                     ), intent(inout)          :: descriptor
  logical                                      , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(atomicExcitationRateCollisionalClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (atomicExcitationRateCollisionalClass), intent(inout) :: self
  integer                                      , intent(in   ) :: stateFile
  type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
  integer(c_size_t                            ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (atomicExcitationRateCollisionalClass)                          , intent(&
&  inout) :: self
  type     (varying_string                      ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                               )                          , intent(in &
&    ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`coolingRate` Return the collisional excitation cooling rate , in units of $\mathrm{J/m^3/s}$, for ion of given `atomicNumber` and `electronNumber` at temperature `T` (in Kelvin). Must have the following interface:

```
 double precision function myImplementationCoolingRate(self,atomicNumber, electronNumber&
&  ,temperature)
  class           (atomicExcitationRateCollisionalClass), intent(inout) :: self
  integer                                               , intent(in   ) :: atomicNumber,&
&   electronNumber
  double precision                                      , intent(in   ) :: temperature
 end double precision function myImplementationCoolingRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(atomicExcitationRateCollisionalClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(atomicExcitationRateCollisionalClass), intent(inout) :: self
 class(atomicExcitationRateCollisionalClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicExcitationRateCollisionalClass), intent(inout) :: self
 integer                                      , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`atomicExcitationRateCollisionalScholzWalters1991` Atomic collisional excitation using the fitting functions of Scholz and Walters [1991].

Atomic ionization potentials.

Additional implementations for atomic ionization potentials. are added using the `atomicIonizationPotential` class. The implementation should be placed in a file containing the directive:

```
!# <atomicIonizationPotential name="atomicIonizationPotentialMyImplementation">
!# <description>A short description of the implementation.</description>
!# </atomicIonizationPotential>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `atomicIonizationPotentialMyImplementation`. The file *must* define a type that extends the `atomicIonizationPotentialClass` class (or extends another type which is itself an extension of the `atomicIonizationPotentialClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (atomicIonizationPotentialClass), intent(inout)          :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (atomicIonizationPotentialClass), intent(inout)          :: self
 type   (inputParameters               ), intent(inout)          :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(atomicIonizationPotentialClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`potential` Returns the ionization potential (in units of eV) for a given atom in a given ionization state. Must have the following interface:

```
double precision function myImplementationPotential(self,atomicNumber, electronNumber)
 class  (atomicIonizationPotentialClass), intent(inout) :: self
 integer                                , intent(in   ) :: atomicNumber, electronNumber
end double precision function myImplementationPotential
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicIonizationPotentialClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (atomicIonizationPotentialClass)                          , intent(inout) ::&
&   self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) ::&
&   allowedParameters
 character(len=*                        )                          , intent(in   ) ::&
&   sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(atomicIonizationPotentialClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(atomicIonizationPotentialClass), intent(inout) :: self
 class(atomicIonizationPotentialClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicIonizationPotentialClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`atomicIonizationPotentialVerner` Implements an atomic ionization potential class, which provides potentials for all ionization stages of all atoms from H to Zn using data taken from Dima Verner's code.

Atomic Collisional Ionization

Additional implementations for atomic collisional ionization are added using the `atomicIonizationRateCollisional` class. The implementation should be placed in a file containing the directive:

```
!# <atomicIonizationRateCollisional name="atomicIonizationRateCollisionalMyImplementation">
!# <description>A short description of the implementation.</description>
!# </atomicIonizationRateCollisional>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `atomicIonizationRateCollisionalMyImplementation`. The file *must* define a type that extends the `atomicIonizationRateCollisionalClass` class (or extends another type which is itself an extension of the `atomicIonizationRateCollisionalClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (atomicIonizationRateCollisionalClass), intent(inout)          :: self
```

```
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (atomicIonizationRateCollisionalClass), intent(inout)           :: self
  type   (inputParameters                     ), intent(inout)           :: descriptor
  logical                                      , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(atomicIonizationRateCollisionalClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (atomicIonizationRateCollisionalClass), intent(inout) :: self
  integer                                      , intent(in   ) :: stateFile
  type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
  integer(c_size_t                            ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (atomicIonizationRateCollisionalClass)                          , intent(&
&  inout) :: self
  type     (varying_string                      ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                               )                          , intent(in &
&    ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`rate` Returns the radiative recombination rate. Must have the following interface:

```
 double precision function myImplementationRate(self,atomicNumber, ionizationState,&
&  temperature)
  class           (atomicIonizationRateCollisionalClass), intent(inout) :: self
  integer                                               , intent(in   ) :: atomicNumber,&
&   ionizationState
  double precision                                      , intent(in   ) :: temperature
 end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(atomicIonizationRateCollisionalClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(atomicIonizationRateCollisionalClass), intent(inout) :: self
 class(atomicIonizationRateCollisionalClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicIonizationRateCollisionalClass), intent(inout) :: self
 integer                                      , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`atomicIonizationRateCollisionalVerner1996` Atomic collisional ionization rates are computed based on the code originally written by Dima Verner.

Atomic dielectronic recombination rates.

Additional implementations for atomic dielectronic recombination rates. are added using the `atomicRecombinationRateDiele` class. The implementation should be placed in a file containing the directive:

```
!# <atomicRecombinationRateDielectronic name="atomicRecombinationRateDielectronicMyImplementation">
!# <description>A short description of the implementation.</description>
!# </atomicRecombinationRateDielectronic>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `atomicRecombinationRateDielectronicMyImplementation`. The file *must* define a type that extends the `atomicRecombinationRateDielectronicClass` class (or extends another type which is itself an extension of the `atomicRecombinationRateDielectronicClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (atomicRecombinationRateDielectronicClass), intent(inout)          :: self
  logical                                          , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (atomicRecombinationRateDielectronicClass), intent(inout)           :: self
 type   (inputParameters                         ), intent(inout)           :: &
&  descriptor
 logical                                          , intent(in   ), optional :: &
&  includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(atomicRecombinationRateDielectronicClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicRecombinationRateDielectronicClass), intent(inout) :: self
 integer                                          , intent(in   ) :: stateFile
 type   (fgsl_file                                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (atomicRecombinationRateDielectronicClass)                         , intent&
&  (inout) :: self
 type     (varying_string                          ), allocatable, dimension(:), intent&
&  (inout) :: allowedParameters
 character(len=*                                   )                         , intent&
&  (in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`rate` Return the dielectroninc recombination rate (in units of $\mathrm{cm}^3\ \mathrm{s}^{-1}$) for the ion of given `atomicNumber` and `electronNumber` at the given `temperature` (in Kelvin). Must have the following interface:

```
double precision function myImplementationRate(self,atomicNumber, electronNumber,&
&  temperature)
 class           (atomicRecombinationRateDielectronicClass), intent(inout) :: self
 integer                                                   , intent(in   ) :: &
&  atomicNumber, electronNumber
 double precision                                          , intent(in   ) :: &
&  temperature
end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(atomicRecombinationRateDielectronicClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(atomicRecombinationRateDielectronicClass), intent(inout) :: self
 class(atomicRecombinationRateDielectronicClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicRecombinationRateDielectronicClass), intent(inout) :: self
 integer                                          , intent(in   ) :: stateFile
 type   (fgsl_file                                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`atomicRecombinationRateDielectronicArnaud1985` Implements an atomic dielectronic recombination class which uses the fits from Aldrovandi and Pequignot [1973], Shull and van Steenberg [1982] and Arnaud and Rothenflug [1985].

Atomic Radiative Recombination

Additional implementations for atomic radiative recombination are added using the `atomicRecombinationRateRadiative` class. The implementation should be placed in a file containing the directive:

```
!# <atomicRecombinationRateRadiative name="atomicRecombinationRateRadiativeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </atomicRecombinationRateRadiative>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `atomicRecombinationRateRadiativeMyImplementation`. The file *must* define a type that extends the `atomicRecombinationRateRadiativeClass` class (or extends another type which is itself an extension of the `atomicRecombinationRateRadiativeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (atomicRecombinationRateRadiativeClass), intent(inout)          :: self
```

```
  logical                                        , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (atomicRecombinationRateRadiativeClass), intent(inout)           :: self
  type   (inputParameters                      ), intent(inout)           :: descriptor
  logical                                       , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(atomicRecombinationRateRadiativeClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (atomicRecombinationRateRadiativeClass), intent(inout) :: self
  integer                                       , intent(in   ) :: stateFile
  type   (fgsl_file                             ), intent(in   ) :: fgslStateFile
  integer(c_size_t                              ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (atomicRecombinationRateRadiativeClass)                          , intent(&
&  inout) :: self
  type     (varying_string                       ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                                )                          , intent(in&
&     ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`rate` Returns the radiative recombination rate. Must have the following interface:

```
 double precision function myImplementationRate(self,atomicNumber, ionizationState,&
&  temperature,level)
  class           (atomicRecombinationRateRadiativeClass), intent(inout)           :: &
&  self
  integer                                                , intent(in   )           :: &
&  atomicNumber, ionizationState
  double precision                                       , intent(in   )           :: &
&  temperature
  integer                                                , intent(in   ), optional :: &
&  level
 end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(atomicRecombinationRateRadiativeClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(atomicRecombinationRateRadiativeClass), intent(inout) :: self
 class(atomicRecombinationRateRadiativeClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (atomicRecombinationRateRadiativeClass), intent(inout) :: self
 integer                                       , intent(in   ) :: stateFile
 type   (fgsl_file                            ), intent(in   ) :: fgslStateFile
 integer(c_size_t                             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`atomicRecombinationRateRadiativeVerner1996` Atomic radiative recombination rates are computed based on the code originally written by Dima Verner.

Black Hole Binaries Initial Separation

Additional implementations for black hole binaries initial separation are added using the `blackHoleBinaryInitialSeparatio` class. The implementation should be placed in a file containing the directive:

```
!# <blackHoleBinaryInitialSeparation name="blackHoleBinaryInitialSeparationMyImplementation">
!# <description>A short description of the implementation.</description>
!# </blackHoleBinaryInitialSeparation>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `blackHoleBinaryInitialSeparationMyImplementation`. The file *must* define a type that extends the `blackHoleBinaryInitialSeparationClass` class (or extends another type which is itself an extension of the `blackHoleBinaryInitialSeparationClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`separationInitial` Computes the initial separation of a newly formed black hole binary black holes. Must have the following interface:

```
double precision function myImplementationSeparationInitial(self,node, nodeHost)
 class(blackHoleBinaryInitialSeparationClass), intent(inout)         :: self
 type (treeNode                              ), intent(inout), target :: node, nodeHost
end double precision function myImplementationSeparationInitial
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (blackHoleBinaryInitialSeparationClass), intent(inout)           :: self
  logical                                       , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (blackHoleBinaryInitialSeparationClass), intent(inout)           :: self
  type   (inputParameters                      ), intent(inout)           :: descriptor
  logical                                       , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(blackHoleBinaryInitialSeparationClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (blackHoleBinaryInitialSeparationClass), intent(inout) :: self
  integer                                       , intent(in   ) :: stateFile
  type   (fgsl_file                             ), intent(in   ) :: fgslStateFile
  integer(c_size_t                              ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (blackHoleBinaryInitialSeparationClass)                          , intent(&
&  inout) :: self
  type     (varying_string                       ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                                )                          , intent(in&
&     ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(blackHoleBinaryInitialSeparationClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(blackHoleBinaryInitialSeparationClass), intent(inout) :: self
 class(blackHoleBinaryInitialSeparationClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (blackHoleBinaryInitialSeparationClass), intent(inout) :: self
 integer                                       , intent(in   ) :: stateFile
 type   (fgsl_file                            ), intent(in   ) :: fgslStateFile
 integer(c_size_t                             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`blackHoleBinaryInitialSeparationSpheroidRadiusFraction` A black hole binary initial separation class in which the radius is a fixed fraction of the scale radius of the larger of the host and satellite spheroids.

`blackHoleBinaryInitialSeparationTidalRadius` A black hole binary initial separation class in which the radius is based on tidal disruption of the satellite galaxy.

`blackHoleBinaryInitialSeparationVolonteri2003` A black hole binary initial separation class based on the model of Volonteri et al. [2003].

Black Hole Binaries Merger

Additional implementations for black hole binaries merger are added using the `blackHoleBinaryMerger` class. The implementation should be placed in a file containing the directive:

```
!# <blackHoleBinaryMerger name="blackHoleBinaryMergerMyImplementation">
!# <description>A short description of the implementation.</description>
!# </blackHoleBinaryMerger>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `blackHoleBinary-MergerMyImplementation`. The file *must* define a type that extends the `blackHoleBinaryMergerClass` class (or extends another type which is itself an extension of the `blackHoleBinaryMergerClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (blackHoleBinaryMergerClass), intent(inout)          :: self
  logical                            , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (blackHoleBinaryMergerClass), intent(inout)          :: self
  type   (inputParameters           ), intent(inout)          :: descriptor
  logical                            , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(blackHoleBinaryMergerClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (blackHoleBinaryMergerClass), intent(inout) :: self
  integer                            , intent(in   ) :: stateFile
  type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
  integer(c_size_t                   ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (blackHoleBinaryMergerClass)                          , intent(inout) :: &
&  self
  type     (varying_string            ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                     )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`merge` The the properties of the black hole resulting from a binary merger. Must have the following interface:

```
 subroutine myImplementationMerge(self,blackHoleMassA    , blackHoleMassB, &
&  blackHoleSpinA    , blackHoleSpinB,blackHoleMassFinal               , &
&  blackHoleSpinFinal)
  class           (blackHoleBinaryMergerClass), intent(inout) :: self
  double precision                            , intent(in   ) :: blackHoleMassA, &
&  blackHoleMassB, blackHoleSpinA, blackHoleSpinB
  double precision                            , intent(  out) :: blackHoleMassFinal, &
&  blackHoleSpinFinal
 end subroutine myImplementationMerge
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(blackHoleBinaryMergerClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(blackHoleBinaryMergerClass), intent(inout) :: self
 class(blackHoleBinaryMergerClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (blackHoleBinaryMergerClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`blackHoleBinaryMergerRezzolla2008` A black hole binary merger class in which the black hole mass and spin resulting from binary mergers utilizing the approximations of Rezzolla et al. [2008].

Black Hole Binaries Recoil

Additional implementations for black hole binaries recoil are added using the `blackHoleBinaryRecoil` class. The implementation should be placed in a file containing the directive:

```
!# <blackHoleBinaryRecoil name="blackHoleBinaryRecoilMyImplementation">
!# <description>A short description of the implementation.</description>
!# </blackHoleBinaryRecoil>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `blackHoleBinaryRecoilMyImplementation`. The file *must* define a type that extends the `blackHoleBinaryRecoilClass` class (or extends another type which is itself an extension of the `blackHoleBinaryRecoilClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (blackHoleBinaryRecoilClass), intent(inout)          :: self
  logical                            , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (blackHoleBinaryRecoilClass), intent(inout)          :: self
 type   (inputParameters           ), intent(inout)          :: descriptor
 logical                            , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(blackHoleBinaryRecoilClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (blackHoleBinaryRecoilClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (blackHoleBinaryRecoilClass)                          , intent(inout) :: &
&  self
 type     (varying_string            ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                     )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`velocity` Computes the recoil velocity of the given pair of merging black holes. Must have the following interface:

```
double precision function myImplementationVelocity(self,blackHole1, blackHole2)
 class(blackHoleBinaryRecoilClass), intent(inout) :: self
 class(nodeComponentBlackHole    ), intent(inout) :: blackHole1, blackHole2
end double precision function myImplementationVelocity
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(blackHoleBinaryRecoilClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(blackHoleBinaryRecoilClass), intent(inout) :: self
 class(blackHoleBinaryRecoilClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (blackHoleBinaryRecoilClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`blackHoleBinaryRecoilCampanelli2007` A black hole binary recoil class in which the recoil velocity is always campanelli2007.

`blackHoleBinaryRecoilZero` A black hole binary recoil class in which the recoil velocity is always zero.

Black Hole Binaries Separation Growth Rate

Additional implementations for black hole binaries separation growth rate are added using the `blackHoleBinarySeparationGr` class. The implementation should be placed in a file containing the directive:

```
!# <blackHoleBinarySeparationGrowthRate name="blackHoleBinarySeparationGrowthRateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </blackHoleBinarySeparationGrowthRate>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `blackHoleBinarySeparationGrowthRateMyImplementation`. The file *must* define a type that extends the `blackHoleBinarySeparationGrowthRateClass` class (or extends another type which is itself an extension of the `blackHoleBinarySeparationGrowthRateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (blackHoleBinarySeparationGrowthRateClass), intent(inout)          :: self
  logical                                          , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (blackHoleBinarySeparationGrowthRateClass), intent(inout)          :: self
  type   (inputParameters                         ), intent(inout)          :: &
&  descriptor
  logical                                          , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(blackHoleBinarySeparationGrowthRateClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (blackHoleBinarySeparationGrowthRateClass), intent(inout) :: self
  integer                                          , intent(in   ) :: stateFile
  type   (fgsl_file                                ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                 ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (blackHoleBinarySeparationGrowthRateClass)                         , intent&
&  (inout) :: self
  type     (varying_string                          ), allocatable, dimension(:), intent&
&  (inout) :: allowedParameters
  character(len=*                                   )                         , intent&
&  (in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(blackHoleBinarySeparationGrowthRateClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`growthRate` Computes the rate of growth of the separation of the given black hole and its binary companion in units of Mpc/Gyr. Must have the following interface:

```
double precision function myImplementationGrowthRate(self,blackHole)
 class(blackHoleBinarySeparationGrowthRateClass), intent(inout) :: self
 class(nodeComponentBlackHole                  ), intent(inout) :: blackHole
end double precision function myImplementationGrowthRate
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(blackHoleBinarySeparationGrowthRateClass), intent(inout) :: self
 class(blackHoleBinarySeparationGrowthRateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (blackHoleBinarySeparationGrowthRateClass), intent(inout) :: self
 integer                                          , intent(in   ) :: stateFile
 type   (fgsl_file                                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`blackHoleBinarySeparationGrowthRateStandard` A black hole binary separation growth class which follows a modified version of Volonteri et al. [2003], including terms for dynamical friction, hardening due to scattering of stars and emission of gravitational waves.

`blackHoleBinarySeparationGrowthRateZero` A black hole binary separation growth class in which the separation does not grow.

Chemical Reaction Rates

Additional implementations for chemical reaction rates are added using the `chemicalReactionRate` class. The implementation should be placed in a file containing the directive:

```
!# <chemicalReactionRate name="chemicalReactionRateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </chemicalReactionRate>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `chemicalReaction-RateMyImplementation`. The file *must* define a type that extends the `chemicalReactionRateClass` class (or extends another type which is itself an extension of the `chemicalReactionRateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (chemicalReactionRateClass), intent(inout)           :: self
  logical                           , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (chemicalReactionRateClass), intent(inout)           :: self
  type   (inputParameters          ), intent(inout)           :: descriptor
  logical                           , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(chemicalReactionRateClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`rates` Return the collisional excitation cooling rate , in units of $\mathrm{J/m^3/s}$, for ion of given `atomicNumber` and `electronNumber` at temperature `T` (in Kelvin). Must have the following interface:

```
 subroutine myImplementationRates(self,temperature,chemicalDensity,radiation,&
&  chemicalRates,node)
  class           (chemicalReactionRateClass), intent(inout) :: self
  double precision                           , intent(in   ) :: temperature
  type            (chemicalAbundances       ), intent(in   ) :: chemicalDensity
  class           (radiationFieldClass      ), intent(inout) :: radiation
  type            (chemicalAbundances       ), intent(inout) :: chemicalRates
  type            (treeNode                 ), intent(inout) :: node
 end subroutine myImplementationRates
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (chemicalReactionRateClass), intent(inout) :: self
  integer                           , intent(in   ) :: stateFile
  type   (fgsl_file                ), intent(in   ) :: fgslStateFile
  integer(c_size_t                 ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (chemicalReactionRateClass)                          , intent(inout) :: self
```

```
  type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
& allowedParameters
  character(len=*                   )                           , intent(in   ) :: &
& sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(chemicalReactionRateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(chemicalReactionRateClass), intent(inout) :: self
 class(chemicalReactionRateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (chemicalReactionRateClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`chemicalReactionRateZero` A chemical reaction rate class in which all rates are zero.

`chemicalReactionRateHydrogenNetwork` A chemical reaction rates for hydrogen using the fits from Abel et al. [1997] and Tegmark et al. [1997].

Chemical State

Additional implementations for chemical state are added using the `chemicalState` class. The implementation should be placed in a file containing the directive:

```
!# <chemicalState name="chemicalStateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </chemicalState>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `chemicalStateMyImplementation`. The file *must* define a type that extends the `chemicalStateClass` class (or extends another type which is itself an extension of the `chemicalStateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (chemicalStateClass), intent(inout)          :: self
  logical                    , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (chemicalStateClass), intent(inout)          :: self
  type   (inputParameters   ), intent(inout)          :: descriptor
  logical                    , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(chemicalStateClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (chemicalStateClass), intent(inout) :: self
  integer                    , intent(in   ) :: stateFile
  type   (fgsl_file         ), intent(in   ) :: fgslStateFile
  integer(c_size_t          ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (chemicalStateClass)                          , intent(inout) :: self
  type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*             )                          , intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`electronDensity` Return the electron density at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm^-3. Must have the following interface:

```
 double precision function myImplementationElectronDensity(self,numberDensityHydrogen, &
&  temperature,gasAbundances,radiation)
  class           (chemicalStateClass ), intent(inout) :: self
  double precision                     , intent(in   ) :: numberDensityHydrogen, &
&  temperature
```

```
 type            (abundances         ), intent(in   ) :: gasAbundances
 class           (radiationFieldClass), intent(inout) :: radiation
end double precision function myImplementationElectronDensity
```

`electronDensityTemperatureLogSlope` Return the logarithmic gradient of electron density with temperature at the given temperature and hydrogen density for the specified set of abundances and radiation field. Must have the following interface:

```
double precision function myImplementationElectronDensityTemperatureLogSlope(self,&
&  numberDensityHydrogen, temperature,gasAbundances,radiation)
 class           (chemicalStateClass ), intent(inout) :: self
 double precision                     , intent(in   ) :: numberDensityHydrogen, &
&  temperature
 type            (abundances         ), intent(in   ) :: gasAbundances
 class           (radiationFieldClass), intent(inout) :: radiation
end double precision function myImplementationElectronDensityTemperatureLogSlope
```

`chemicalDensities` Return the densities of chemical species at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned electron density are cm^{-}3. Must have the following interface:

```
subroutine myImplementationChemicalDensities(self,chemicalDensities,&
&  numberDensityHydrogen, temperature,gasAbundances,radiation)
 class           (chemicalStateClass ), intent(inout) :: self
 type            (chemicalAbundances ), intent(inout) :: chemicalDensities
 double precision                     , intent(in   ) :: numberDensityHydrogen, &
&  temperature
 type            (abundances         ), intent(in   ) :: gasAbundances
 class           (radiationFieldClass), intent(inout) :: radiation
end subroutine myImplementationChemicalDensities
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(chemicalStateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(chemicalStateClass), intent(inout) :: self
 class(chemicalStateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (chemicalStateClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`electronDensityDensityLogSlope` Return the logarithmic gradient of electron density with respect to density at the given temperature and hydrogen density for the specified set of abundances and radiation field. Must have the following interface:

```
 double precision function myImplementationElectronDensityDensityLogSlope(self,&
&  numberDensityHydrogen, temperature,gasAbundances,radiation)
  class           (chemicalStateClass ), intent(inout) :: self
  double precision                     , intent(in   ) :: numberDensityHydrogen, &
&  temperature
  type            (abundances         ), intent(in   ) :: gasAbundances
  class           (radiationFieldClass), intent(inout) :: radiation
 end double precision function myImplementationElectronDensityDensityLogSlope
```

Existing implementations are:

`chemicalStateCIEFile` Class providing chemical state via interpolation of tabulated values read from file. The HDF5 file containing the table should have the following form:

```
HDF5 "chemicalState.hdf5" {
GROUP "/" {
ATTRIBUTE "fileFormat" {
DATATYPE  H5T_STRING {
STRSIZE 1;
STRPAD H5T_STR_NULLTERM;
CSET H5T_CSET_ASCII;
CTYPE H5T_C_S1;
}
DATASPACE  SCALAR
DATA {
(0): "1"
}
}
DATASET "electronDensity" {
DATATYPE  H5T_IEEE_F64LE
DATASPACE  SIMPLE { ( 7, 8 ) / ( 7, 8 ) }
}
DATASET "hiDensity" {
DATATYPE  H5T_IEEE_F64LE
DATASPACE  SIMPLE { ( 7, 8 ) / ( 7, 8 ) }
}
DATASET "hiiDensity" {

}
```

```
}
}
```

The `temperature` dataset should specify temperature (in Kelvin), while the `metallicity` dataset should give the logarithmic metallcity relative to Solar (a value of -999 or less is taken to imply zero metallicity). The `electronDensity` dataset should specify the number density of electrons relative to hydrogen at each temperature/metallicity pair. Optionally `hiDensity` and `hiiDensity` datasets may be added giving the number densities of HI and HII relative to hydrogen respectively The `extrapolateLow` and `extrapolateHigh` attributes of the `temperature` and `metallicity` datasets specify how the cooling rate should be extrapolated in the low and high vale limits. Allowed options for these attributes are:

`zero` The electron density is set to zero beyond the relevant limit.

`fixed` The electron density is held fixed at the value at the relevant limit.

`power law` The electron density is extrapolated assuming a power-law dependence beyond the relevant limit. This option is only allowed if the electron density is everywhere positive.

If the electron density is everywhere positive the interpolation will be done in the logarithmic of temperature, metallicity[3] and electron density. Otherwise, interpolation is linear in these quantities. The electron density is scaled assuming a linear dependence on hydrogen density.

`chemicalStateAtomicCIECloudy` Class providing chemical state by utilizing the CLOUDY code to compute state in collisional ionization equilibrium. CLOUDY will be downloaded, compiled and run automatically if necessary[4].

Infall rates in cold mode accretion.

Additional implementations for infall rates in cold mode accretion. are added using the `coldModeInfallRate` class. The implementation should be placed in a file containing the directive:

```
!# <coldModeInfallRate name="coldModeInfallRateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coldModeInfallRate>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coldModeInfallRateMyImplementation`. The file *must* define a type that extends the `coldModeInfallRateClass` class (or extends another type which is itself an extension of the `coldModeInfallRateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

[3] The exception is if the first electron density is tabulated for zero metallicity. In that case, a linear interpolation in metallicity is always used between zero and the first non-zero tabulated metallicity.

[4] CLOUDY is used to generate a file which contains a tabulation of the chemical state suitable for reading by the `CIE from file` method. Generation of the tabulation typically takes several hours, but only needs to be done once as the stored table is simply read back in on later runs.

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (coldModeInfallRateClass), intent(inout)           :: self
  logical                         , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coldModeInfallRateClass), intent(inout)           :: self
 type   (inputParameters        ), intent(inout)           :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coldModeInfallRateClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coldModeInfallRateClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`infallRate` Returns the cold mode infall rate for `thisNode` (in units of $M_\odot$ Gyr^{-1}). Must have the following interface:

```
double precision function myImplementationInfallRate(self,node)
 class(coldModeInfallRateClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationInfallRate
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coldModeInfallRateClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coldModeInfallRateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coldModeInfallRateClass), intent(inout) :: self
 class(coldModeInfallRateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coldModeInfallRateClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coldModeInfallRateDynamicalTime` A dynamicalTime cooling time calculation (based on the ratio of the thermal energy density to the volume cooling rate). See §12.7.1.

Conditional Mass Function

Additional implementations for conditional mass function are added using the `conditionalMassFunction` class. The implementation should be placed in a file containing the directive:

```
!# <conditionalMassFunction name="conditionalMassFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </conditionalMassFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `conditionalMassFunctionMyImplementation`. The file *must* define a type that extends the `conditionalMassFunctionClass` class (or extends another type which is itself an extension of the `conditionalMassFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`massFunction` Return the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$. Must have the following interface:

```
 double precision function myImplementationMassFunction(self,massHalo  , mass,galaxyType&
&  )
  class           (conditionalMassFunctionClass), intent(inout)           :: self
  double precision                              , intent(in   )           :: massHalo, &
&  mass
  integer                                       , intent(in   ), optional :: galaxyType
 end double precision function myImplementationMassFunction
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (conditionalMassFunctionClass), intent(inout)           :: self
  logical                              , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (conditionalMassFunctionClass), intent(inout)           :: self
  type   (inputParameters             ), intent(inout)           :: descriptor
  logical                              , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(conditionalMassFunctionClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (conditionalMassFunctionClass), intent(inout) :: self
  integer                              , intent(in   ) :: stateFile
  type   (fgsl_file                   ), intent(in   ) :: fgslStateFile
  integer(c_size_t                    ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (conditionalMassFunctionClass)                          , intent(inout) :: &
&  self
  type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(conditionalMassFunctionClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(conditionalMassFunctionClass), intent(inout) :: self
 class(conditionalMassFunctionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`massFunctionVariance` Return the variance in the cumulative conditional mass function, $\langle N(M_\star|M_{\rm halo})\rangle \equiv \phi(M_\star|M_{\rm halo})$. Must have the following interface:

```
double precision function myImplementationMassFunctionVariance(self,massHalo,massLow,&
&  massHigh)
 class           (conditionalMassFunctionClass), intent(inout) :: self
 double precision                              , intent(in   ) :: massHalo, massLow, &
&  massHigh
 end double precision function myImplementationMassFunctionVariance
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (conditionalMassFunctionClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`conditionalMassFunctionBehroozi2010` A class which implements the conditional mass function using the fiting functions of Behroozi et al. [2010]. See §12.8.1.

Cooling Function

Additional implementations for cooling function are added using the `coolingFunction` class. The implementation should be placed in a file containing the directive:

```
!# <coolingFunction name="coolingFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingFunctionMyImplementation`. The file *must* define a type that extends the `coolingFunctionClass` class (or extends another type which is itself an extension of the `coolingFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (coolingFunctionClass), intent(inout)          :: self
  logical                      , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (coolingFunctionClass), intent(inout)          :: self
  type   (inputParameters     ), intent(inout)          :: descriptor
  logical                      , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(coolingFunctionClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (coolingFunctionClass), intent(inout) :: self
  integer                      , intent(in   ) :: stateFile
  type   (fgsl_file           ), intent(in   ) :: fgslStateFile
  integer(c_size_t            ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (coolingFunctionClass)                          , intent(inout) :: self
  type     (varying_string      ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*               )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`coolingFunction` Return the cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Units of the returned cooling function are the traditional ergs $\mathrm{cm}^{-}3\ \mathrm{s}^{-1}$. Must have the following interface:

```
 double precision function myImplementationCoolingFunction(self,numberDensityHydrogen, &
&  temperature,gasAbundances,chemicalDensities,radiation)
  class           (coolingFunctionClass), intent(inout) :: self
  double precision                      , intent(in   ) :: numberDensityHydrogen, &
&  temperature
  type            (abundances          ), intent(in   ) :: gasAbundances
  type            (chemicalAbundances  ), intent(in   ) :: chemicalDensities
  class           (radiationFieldClass ), intent(inout) :: radiation
 end double precision function myImplementationCoolingFunction
```

`coolingFunctionDensityLogSlope` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln\rho$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Must have the following interface:

```
 double precision function myImplementationCoolingFunctionDensityLogSlope(self,&
&  numberDensityHydrogen, temperature,gasAbundances,chemicalDensities,radiation)
  class           (coolingFunctionClass), intent(inout) :: self
  double precision                      , intent(in   ) :: numberDensityHydrogen, &
&  temperature
  type            (abundances          ), intent(in   ) :: gasAbundances
  type            (chemicalAbundances  ), intent(in   ) :: chemicalDensities
  class           (radiationFieldClass ), intent(inout) :: radiation
 end double precision function myImplementationCoolingFunctionDensityLogSlope
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingFunctionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingFunctionClass), intent(inout) :: self
 class(coolingFunctionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingFunctionClass), intent(inout) :: self
 integer                      , intent(in   ) :: stateFile
 type   (fgsl_file           ), intent(in   ) :: fgslStateFile
 integer(c_size_t            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`coolingFunctionTemperatureLogSlope` Return $\mathrm{d}\ln\Lambda/\mathrm{d}\ln T$ for a cooling function at the given temperature and hydrogen density for the specified set of abundances and radiation field. Must have the following interface:

```
 double precision function myImplementationCoolingFunctionTemperatureLogSlope(self,&
&  numberDensityHydrogen, temperature,gasAbundances,chemicalDensities,radiation)
  class           (coolingFunctionClass), intent(inout) :: self
  double precision                      , intent(in   ) :: numberDensityHydrogen, &
&  temperature
  type            (abundances          ), intent(in   ) :: gasAbundances
  type            (chemicalAbundances  ), intent(in   ) :: chemicalDensities
  class           (radiationFieldClass ), intent(inout) :: radiation
 end double precision function myImplementationCoolingFunctionTemperatureLogSlope
```

Existing implementations are:

`coolingFunctionCMBCompton` Class providing a cooling function due to Compton scattering off of CMB photons.

`coolingFunctionSummation` Class providing a cooling function which sums over other cooling functions.

`coolingFunctionMolecularHydrogenGalliPalla` Cooling function class which implements cooling from molecular hydrogen using the cooling function of Galli and Palla [1998].

`coolingFunctionAtomicCIECloudy` Class providing cooling function by utilizing the Cloudy code to compute cooling in collisional ionization equilibrium. Cloudy will be downloaded, compiled and run automatically if necessary[5].

`coolingFunctionCIEFile` Class providing a cooling function interpolated from a table read from file. The HDF5 file containing the table should have the following form:

```
HDF5 "coolingFunction.hdf5" {
GROUP "/" {
ATTRIBUTE "fileFormat" {
DATATYPE  H5T_STRING {
STRSIZE 1;
STRPAD H5T_STR_NULLTERM;
CSET H5T_CSET_ASCII;
CTYPE H5T_C_S1;
}
DATASPACE  SCALAR
DATA {
(0): "1"
}
}
DATASET "coolingRate" {
DATATYPE  H5T_IEEE_F64LE
DATASPACE  SIMPLE { ( 7, 8 ) / ( 7, 8 ) }
}
DATASET "metallicity" {
DATATYPE  H5T_IEEE_F64LE
DATASPACE  SIMPLE { ( 8 ) / ( 8 ) }
ATTRIBUTE "extrapolateHigh" {
DATATYPE  H5T_STRING {
STRSIZE 3;
STRPAD H5T_STR_NULLTERM;
CSET H5T_CSET_ASCII;
CTYPE H5T_C_S1;
}
DATASPACE  SCALAR
DATA {
(0): "fix"
}
}
```

[5] Cloudy is used to generate a file which contains a tabulation of the cooling function suitable for reading by the `CIE from file` method. Generation of the tabulation typically takes several hours, but only needs to be done once as the stored table is simply read back in on later runs.

```
ATTRIBUTE "extrapolateLow" {
DATATYPE  H5T_STRING {
STRSIZE 3;
STRPAD H5T_STR_NULLTERM;
CSET H5T_CSET_ASCII;
CTYPE H5T_C_S1;
}
DATASPACE  SCALAR
DATA {
(0): "fix"
}
}
}
DATASET "temperature" {
DATATYPE  H5T_IEEE_F64LE
DATASPACE  SIMPLE { ( 7 ) / ( 7 ) }
ATTRIBUTE "extrapolateHigh" {
DATATYPE  H5T_STRING {
STRSIZE 8;
STRPAD H5T_STR_NULLTERM;
CSET H5T_CSET_ASCII;
CTYPE H5T_C_S1;
}
DATASPACE  SCALAR
DATA {
(0): "powerLaw"
}
}
ATTRIBUTE "extrapolateLow" {
DATATYPE  H5T_STRING {
STRSIZE 8;
STRPAD H5T_STR_NULLTERM;
CSET H5T_CSET_ASCII;
CTYPE H5T_C_S1;
}
DATASPACE  SCALAR
DATA {
(0): "powerLaw"
}
}
}
}
}
```

The `temperature` dataset should specify temperature (in Kelvin), while the `metallicity` dataset should give the logarithmic metallcity relative to Solar (a value of -999 or less is taken to imply zero metallicity). The `coolingRate` dataset should specify the cooling function (in ergs cm^3 s^{-1} computed for a hydrogen density of 1 cm^{-3}) respectively at each temperature/metallicity pair. The `extrapolateLow` and `extrapolateHigh` attributes of the `temperature` and `metallicity` datasets specify how the cooling rate should be extrapolated in the low and high vale limits. Allowed options

for these attributes are:

`zero` The cooling function is set to zero beyond the relevant limit.

`fixed` The cooling function is held fixed at the value at the relevant limit.

`powerLaw` The cooling function is extrapolated assuming a power-law dependence beyond the relevant limit. This option is only allowed if the cooling function is everywhere positive.

If the cooling function is everywhere positive the interpolation will be done in the logarithm of temperature, metallicity[6] and cooling function. Otherwise, interpolation is linear in these quantities. The cooling function is scaled assuming a quadratic dependence on hydrogen density.

Cooling Infall Radius

Additional implementations for cooling infall radius are added using the `coolingInfallRadius` class. The implementation should be placed in a file containing the directive:

```
!# <coolingInfallRadius name="coolingInfallRadiusMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingInfallRadius>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingInfallRadiusMyImplementation`. The file *must* define a type that extends the `coolingInfallRadiusClass` class (or extends another type which is itself an extension of the `coolingInfallRadiusClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`radiusIncreaseRate` Return the rate at which the infall radius grows for `node` (in units of Mpc/Gyr). Must have the following interface:

```
double precision function myImplementationRadiusIncreaseRate(self,node)
 class(coolingInfallRadiusClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationRadiusIncreaseRate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (coolingInfallRadiusClass), intent(inout)          :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

[6] The exception is if the first cooling function is tabulated for zero metallicity. In that case, a linear interpolation in metallicity is always used between zero and the first non-zero tabulated metallicity.

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coolingInfallRadiusClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coolingInfallRadiusClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`radius` Return the infall radius for `node` (in units of Mpc). Must have the following interface:

```
double precision function myImplementationRadius(self,node)
 class(coolingInfallRadiusClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingInfallRadiusClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coolingInfallRadiusClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingInfallRadiusClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingInfallRadiusClass), intent(inout) :: self
 class(coolingInfallRadiusClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingInfallRadiusClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coolingInfallRadiusCoolingRadius` A simple infall radius calculation, simply assuming that the infall radius equals the cooling radius.

`coolingInfallRadiusCoolingFreefall` An infall radius calculation in which the infall radius is the smaller of the cooling and freefall radii.

Cooling radii.

Additional implementations for cooling radii. are added using the `coolingRadius` class. The implementation should be placed in a file containing the directive:

```
!# <coolingRadius name="coolingRadiusMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingRadius>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingRadiusMyImplementation`. The file *must* define a type that extends the `coolingRadiusClass` class (or extends another type which is itself an extension of the `coolingRadiusClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (coolingRadiusClass), intent(inout)           :: self
  logical                    , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coolingRadiusClass), intent(inout)           :: self
 type   (inputParameters   ), intent(inout)           :: descriptor
 logical                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`radiusGrowthRate` Returns the rate of increase of the cooling radius for gas in the hot atmosphere surrounding the galaxy in `node` in units of Mpc/Gyr. Must have the following interface:

```
double precision function myImplementationRadiusGrowthRate(self,node)
 class(coolingRadiusClass), intent(inout) :: self
 type (treeNode          ), intent(inout) :: node
end double precision function myImplementationRadiusGrowthRate
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coolingRadiusClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`radius` Returns the cooling radius for gas in the hot atmosphere surrounding the galaxy in `node` in units of Mpc. Must have the following interface:

```
double precision function myImplementationRadius(self,node)
 class(coolingRadiusClass), intent(inout)         :: self
 type (treeNode          ), intent(inout), target :: node
end double precision function myImplementationRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingRadiusClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coolingRadiusClass)                            , intent(inout) :: self
 type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*             )                            , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingRadiusClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingRadiusClass), intent(inout) :: self
 class(coolingRadiusClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingRadiusClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coolingRadiusIsothermal` A cooling radius class for isothermal halos. Computes the cooling radius by assuming that the hot gas density profile is an isothermal profile ($\rho(r) \propto r^{-2}$), and that the cooling rate scales as density squared, $\dot{E} \propto \rho^2$, such that the cooling time scales as inverse density, $t_{\rm cool} \propto \rho^{-1}$. Consequently, the cooling radius grows as the square root of the time available for cooling.

`coolingRadiusBetaProfile` A cooling radius class for β-profile halos. Computes the cooling radius by assuming that the hot gas density profile is a β-profile ($\rho(r) \propto [r^2+r_{\rm c}^2]^{-1}$), and that the cooling rate scales as density squared, $\dot{E} \propto \rho^2$, such that the cooling time scales as inverse density, $t_{\rm cool} \propto \rho^{-1}$. Consequently, the cooling radius is given by

$$r_{\rm cool} = r_{\rm virial} \left(\left[\frac{t_{\rm avail}}{t_0} - 1 \right] \left[\frac{t_{\rm virial}}{t_0} - 1 \right]^{-1} \right)^{1/2}, \tag{16.2}$$

where t_0, and $t_{\rm virial}$ are the cooling times at zero radius and the virial radius respectively.

`coolingRadiusSimple` A cooling radius class computes the cooling radius by seeking the radius at which the time available for cooling equals the cooling time. The growth rate is determined consistently based on the slope of the density profile, the density dependence of the cooling function and the rate at which the time available for cooling is increasing. This method assumes that the cooling time is a monotonic function of radius.

Cooling rates.

Additional implementations for cooling rates. are added using the `coolingRate` class. The implementation should be placed in a file containing the directive:

```
!# <coolingRate name="coolingRateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingRate>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingRateMyImplementation`. The file *must* define a type that extends the `coolingRateClass` class (or

extends another type which is itself an extension of the `coolingRateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
& )
 class  (coolingRateClass), intent(inout)          :: self
 logical                  , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coolingRateClass), intent(inout)          :: self
 type   (inputParameters ), intent(inout)          :: descriptor
 logical                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coolingRateClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingRateClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coolingRateClass)                          , intent(inout) :: self
 type     (varying_string  ), allocatable, dimension(:), intent(inout) :: &
& allowedParameters
 character(len=*           )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`rate` Returns the cooling rate of gas in the hot atmosphere surrounding the galaxy in `node` in units of $M_\odot$/Gyr. Must have the following interface:

```
double precision function myImplementationRate(self,node)
 class(coolingRateClass), intent(inout) :: self
 type (treeNode        ), intent(inout) :: node
end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingRateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingRateClass), intent(inout) :: self
 class(coolingRateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingRateClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coolingRateSimpleScaling` A cooling rate class in which the cooling rate scales with the mass of the halo.

`coolingRateZero` A cooling rate class in which the cooling rate is always zero.

`coolingRateMultiplier` A cooling rate class which modifies another cooling rate by multiplying the rate by a fixed value.

`coolingRateSimple` A cooling rate class in which the cooling rate equals the mass of hot gas divided by a fixed timescale.

`coolingRateCutOff` A cooling rate class which modifies another cooling rate by cutting off cooling above some virial velocity.

`coolingRateCole2000` Computes the mass cooling rate in a hot gas halo utilizing the Cole et al. [2000] method. This is based on the properties of the halo at formation time, and gives a zero cooling rate when the cooling radius exceeds the virial radius.

`coolingRateVelocityMaximumScaling` A cooling rate class in which the cooling rate scales with the peak circular velocity in the halo.

`coolingRateWhiteFrenk1991` A cooling rate class for the White and Frenk [1991] cooling rate calculation.

`coolingRateNoCoolingSatellites` A cooling rate class which modifies another cooling rate by cutting off cooling in satellites

Specific angular momentua of cooling gas.

Additional implementations for specific angular momentua of cooling gas. are added using the `coolingSpecificAngularMomen` class. The implementation should be placed in a file containing the directive:

```
!# <coolingSpecificAngularMomentum name="coolingSpecificAngularMomentumMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingSpecificAngularMomentum>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingSpecificAngularMomentumMyImplementation`. The file *must* define a type that extends the `coolingSpecificAngularMomentumClass` class (or extends another type which is itself an extension of the `coolingSpecificAngularMomentumClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (coolingSpecificAngularMomentumClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coolingSpecificAngularMomentumClass), intent(inout)           :: self
 type   (inputParameters                    ), intent(inout)           :: descriptor
 logical                                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`angularMomentumSpecific` Return the specific angular momentum (in units of km/s Mpc) of cooling gas in `node`. Must have the following interface:

```
double precision function myImplementationAngularMomentumSpecific(self,node,radius)
 class           (coolingSpecificAngularMomentumClass), intent(inout) :: self
 type            (treeNode                           ), intent(inout) :: node
 double precision                                     , intent(in   ) :: radius
end double precision function myImplementationAngularMomentumSpecific
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coolingSpecificAngularMomentumClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingSpecificAngularMomentumClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coolingSpecificAngularMomentumClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingSpecificAngularMomentumClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingSpecificAngularMomentumClass), intent(inout) :: self
 class(coolingSpecificAngularMomentumClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingSpecificAngularMomentumClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coolingSpecificAngularMomentumMean` A specific angular momentum of cooling gas class in which all gas has the mean specific angular momentum of the hot gas halo.

`coolingSpecificAngularMomentumConstantRotation` A specific angular momentum of cooling gas class which assumes a constant rotation velocity as a function of radius.

Cooling times.

Additional implementations for cooling times. are added using the `coolingTime` class. The implementation should be placed in a file containing the directive:

```
!# <coolingTime name="coolingTimeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingTime>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingTimeMyImplementation`. The file *must* define a type that extends the `coolingTimeClass` class (or extends another type which is itself an extension of the `coolingTimeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (coolingTimeClass), intent(inout)           :: self
 logical                  , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coolingTimeClass), intent(inout)           :: self
 type   (inputParameters ), intent(inout)           :: descriptor
 logical                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coolingTimeClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`time` Returns the cooling time for gas in the hot atmosphere surrounding the galaxy in units of Gyr. Must have the following interface:

```
double precision function myImplementationTime(self,temperature      , density,&
&  gasAbundances,chemicalDensities,radiation)
 class           (coolingTimeClass   ), intent(inout) :: self
 double precision                     , intent(in   ) :: temperature, density
 type            (abundances         ), intent(in   ) :: gasAbundances
 type            (chemicalAbundances ), intent(in   ) :: chemicalDensities
 class           (radiationFieldClass), intent(inout) :: radiation
end double precision function myImplementationTime
```

`gradientTemperatureLogarithmic` Returns the logarithmic derivative of cooling time with respect to temperature for gas in the hot atmosphere surrounding the galaxy. Must have the following interface:

```
double precision function myImplementationGradientTemperatureLogarithmic(self,&
&  temperature      , density,gasAbundances,chemicalDensities,radiation)
 class           (coolingTimeClass   ), intent(inout) :: self
 double precision                     , intent(in   ) :: temperature, density
 type            (abundances         ), intent(in   ) :: gasAbundances
 type            (chemicalAbundances ), intent(in   ) :: chemicalDensities
 class           (radiationFieldClass), intent(inout) :: radiation
end double precision function myImplementationGradientTemperatureLogarithmic
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingTimeClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`gradientDensityLogarithmic` Returns the logarithmic derivative of cooling time with respect to density for gas in the hot atmosphere surrounding the galaxy. Must have the following interface:

```
double precision function myImplementationGradientDensityLogarithmic(self,temperature  &
&      , density,gasAbundances,chemicalDensities,radiation)
 class           (coolingTimeClass   ), intent(inout) :: self
 double precision                     , intent(in   ) :: temperature, density
 type            (abundances         ), intent(in   ) :: gasAbundances
 type            (chemicalAbundances ), intent(in   ) :: chemicalDensities
 class           (radiationFieldClass), intent(inout) :: radiation
end double precision function myImplementationGradientDensityLogarithmic
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coolingTimeClass)                          , intent(inout) :: self
 type     (varying_string  ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*           )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingTimeClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingTimeClass), intent(inout) :: self
 class(coolingTimeClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingTimeClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coolingTimeSimple` A simple cooling time calculation (based on the ratio of the thermal energy density to the volume cooling rate). See §12.9.8.

Time available for cooling

Additional implementations for time available for cooling are added using the `coolingTimeAvailable` class. The implementation should be placed in a file containing the directive:

```
!# <coolingTimeAvailable name="coolingTimeAvailableMyImplementation">
!# <description>A short description of the implementation.</description>
!# </coolingTimeAvailable>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `coolingTimeAvailable-MyImplementation`. The file *must* define a type that extends the `coolingTimeAvailableClass` class (or extends another type which is itself an extension of the `coolingTimeAvailableClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (coolingTimeAvailableClass), intent(inout)          :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (coolingTimeAvailableClass), intent(inout)          :: self
 type   (inputParameters          ), intent(inout)          :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(coolingTimeAvailableClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingTimeAvailableClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (coolingTimeAvailableClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`timeAvailable` Return the time available for cooling in `node` in units of Gyr. Must have the following interface:

```
double precision function myImplementationTimeAvailable(self,node)
 class(coolingTimeAvailableClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationTimeAvailable
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(coolingTimeAvailableClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(coolingTimeAvailableClass), intent(inout) :: self
 class(coolingTimeAvailableClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`timeAvailableIncreaseRate` Return the rate at which the time available for cooling increases in `node` (dimensionless). Must have the following interface:

```
double precision function myImplementationTimeAvailableIncreaseRate(self,node)
 class(coolingTimeAvailableClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationTimeAvailableIncreaseRate
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (coolingTimeAvailableClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`coolingTimeAvailableFormationTime` A time available for cooling class which implements the algorithm of Cole et al. [2000], that is, the time available is the time since the halo "formed".

`coolingTimeAvailableWhiteFrenk1991` A time available for cooling class which implements the algorithm of White and Frenk [1991]. The time available is set to a value between the age of the Universe and the dynamical time of the halo, depending on the interpolating parameter `[ageFactor]`.

Mass Variance of Cosmological Density Field

Additional implementations for mass variance of cosmological density field are added using the `cosmologicalMassVariance` class. The implementation should be placed in a file containing the directive:

```
!# <cosmologicalMassVariance name="cosmologicalMassVarianceMyImplementation">
!# <description>A short description of the implementation.</description>
!# </cosmologicalMassVariance>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `cosmologicalMassVarianceMyImplementation`. The file *must* define a type that extends the `cosmologicalMassVarianceClass` class (or extends another type which is itself an extension of the `cosmologicalMassVarianceClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`powerNormalization` Return the normalization of the power spectrum. Must have the following interface:

```
double precision function myImplementationPowerNormalization(self)
 class(cosmologicalMassVarianceClass), intent(inout) :: self
end double precision function myImplementationPowerNormalization
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (cosmologicalMassVarianceClass), intent(inout)          :: self
  logical                               , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (cosmologicalMassVarianceClass), intent(inout)          :: self
  type   (inputParameters              ), intent(inout)          :: descriptor
  logical                               , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`rootVarianceAndLogarithmicGradient` Return the value and logarithmic gradient with respect to mass of the root-variance of the cosmological density field. Must have the following interface:

```
 subroutine myImplementationRootVarianceAndLogarithmicGradient(self,mass,rootVariance, &
&  rootVarianceLogarithmicGradient)
  class           (cosmologicalMassVarianceClass), intent(inout) :: self
  double precision                               , intent(in   ) :: mass
  double precision                               , intent(  out) :: rootVariance, &
&  rootVarianceLogarithmicGradient
 end subroutine myImplementationRootVarianceAndLogarithmicGradient
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(cosmologicalMassVarianceClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (cosmologicalMassVarianceClass), intent(inout) :: self
  integer                               , intent(in   ) :: stateFile
  type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
  integer(c_size_t                     ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`sigma8` Return the value of σ_8. Must have the following interface:

```
 double precision function myImplementationSigma8(self)
  class(cosmologicalMassVarianceClass), intent(inout) :: self
 end double precision function myImplementationSigma8
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (cosmologicalMassVarianceClass)                          , intent(inout) :: &
&  self
  type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(cosmologicalMassVarianceClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`rootVarianceLogarithmicGradient` Return the logarithmic gradient of the root-variance of the cosmological density field with respect to mass. Must have the following interface:

```
double precision function myImplementationRootVarianceLogarithmicGradient(self,mass)
 class           (cosmologicalMassVarianceClass), intent(inout) :: self
 double precision                               , intent(in   ) :: mass
end double precision function myImplementationRootVarianceLogarithmicGradient
```

`mass` Return the mass corresponding to the given `rootVariance` of the cosmological density field. Must have the following interface:

```
double precision function myImplementationMass(self,rootVariance)
 class           (cosmologicalMassVarianceClass), intent(inout) :: self
 double precision                               , intent(in   ) :: rootVariance
end double precision function myImplementationMass
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(cosmologicalMassVarianceClass), intent(inout) :: self
 class(cosmologicalMassVarianceClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`rootVariance` Return the root-variance of the cosmological density field. Must have the following interface:

```
double precision function myImplementationRootVariance(self,mass)
 class           (cosmologicalMassVarianceClass), intent(inout) :: self
 double precision                               , intent(in   ) :: mass
end double precision function myImplementationRootVariance
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (cosmologicalMassVarianceClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`cosmologicalMassVarianceFilteredPower` Mass variance of cosmological density fields computed from a filtered power spectrum. The normalization of the mass variance is specified via the `[sigma_8]` parameter, which defines the linear theory root-variance of the density field in spheres of radii $8h^{-1}$Mpc. The mass variance, $\sigma(M)$, is found by integration over the linear theory power spectrum, with the specified power spectrum window function. The fractional tolerance for this integration can be set via the `[tolerance]` parameter. (The normalization of $\sigma(M)$ to give the desired σ_8 always uses a top-hat window function. For this integration the tolerance can be set via the `[toleranceTopHat]` parameter.) This is tabulated across the required range. Cubic spline interpolation is then used to interpolate in this table to give $\sigma(M)$ at any required value of M. The tabulation is always forced to be monotonically decreasing with M. However, the interpolation is not necessarily monotonic—for example in cases where $\sigma(M)$ becomes constant or close to constant as a function of M the interpolation can become non-monotonic over some ranges of M. If strict monotonicity is required set `[monotonicInterpolation]`=`true`. This causes a monotonic spline interpolator to be used instead which gaurantees monotonicity.

`cosmologicalMassVariancePeakBackgroundSplit` The cosmological mass variance is computed by taking the variance from some other mass variance class, $\sigma^2(M)$, and offsetting it by the variance of the background in the peak-background split model, $\sigma^2(M_\mathrm{e})$, where M_e is the mass contained within the region defined as the background.

Cosmology Functions

Additional implementations for cosmology functions are added using the `cosmologyFunctions` class. The implementation should be placed in a file containing the directive:

```
!# <cosmologyFunctions name="cosmologyFunctionsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </cosmologyFunctions>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `cosmologyFunctionsMyImplementation`. The file *must* define a type that extends the `cosmologyFunctionsClass` class (or extends another type which is itself an extension of the `cosmologyFunctionsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hubbleParameterEpochal` Returns the Hubble parameter at the requested cosmological time, `time`, or expansion factor, `expansionFactor`. Must have the following interface:

```
 double precision function myImplementationHubbleParameterEpochal(self,time,&
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationHubbleParameterEpochal
```

`omegaDarkEnergyEpochal` Return the dark energy density parameter at expansion factor `expansionFactor`. Must have the following interface:

```
 double precision function myImplementationOmegaDarkEnergyEpochal(self,time  , &
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationOmegaDarkEnergyEpochal
```

`equationOfStateDarkEnergy` HASH(0x1fe6c28) Must have the following interface:

```
 double precision function myImplementationEquationOfStateDarkEnergy(self,time, &
&  expansionFactor)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
 end double precision function myImplementationEquationOfStateDarkEnergy
```

`expansionFactor` Returns the expansion factor at cosmological time `time`. Must have the following interface:

```
 double precision function myImplementationExpansionFactor(self,time)
  class           (cosmologyFunctionsClass), intent(inout) :: self
  double precision                         , intent(in   ) :: time
 end double precision function myImplementationExpansionFactor
```

`equalityEpochMatterRadiation` Return the epoch of matter-radiation magnitude equality (either expansion factor or cosmic time). Must have the following interface:

```
 double precision function myImplementationEqualityEpochMatterRadiation(self,requestType&
&  )
  class  (cosmologyFunctionsClass), intent(inout)           :: self
  integer                         , intent(in   ), optional :: requestType
 end double precision function myImplementationEqualityEpochMatterRadiation
```

`cosmicTime` Return the cosmological age at the given expansion factor. Must have the following interface:

```
 double precision function myImplementationCosmicTime(self,expansionFactor,&
&  collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   )           :: expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationCosmicTime
```

`equalityEpochMatterDarkEnergy` Return the epoch of matter-dark energy magnitude equality (either expansion factor or cosmic time). Must have the following interface:

```
 double precision function myImplementationEqualityEpochMatterDarkEnergy(self,&
&  requestType)
  class  (cosmologyFunctionsClass), intent(inout)           :: self
  integer                         , intent(in   ), optional :: requestType
 end double precision function myImplementationEqualityEpochMatterDarkEnergy
```

`distanceComovingConvert` Convert between different measures of comoving distance. Must have the following interface:

```
 double precision function myImplementationDistanceComovingConvert(self,output,&
&  distanceLuminosity, distanceModulus, distanceModulusKCorrected, redshift)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  integer                                  , intent(in   )           :: output
  double precision                         , intent(in   ), optional :: &
&  distanceLuminosity, distanceModulus, distanceModulusKCorrected, redshift
 end double precision function myImplementationDistanceComovingConvert
```

`temperatureCMBEpochal` Return the temperature of the cosmic microwave background at `expansionFactor`. Must have the following interface:

```
 double precision function myImplementationTemperatureCMBEpochal(self,time  , &
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationTemperatureCMBEpochal
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (cosmologyFunctionsClass), intent(inout)           :: self
  type   (inputParameters        ), intent(inout)           :: descriptor
  logical                         , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (cosmologyFunctionsClass), intent(inout) :: self
  integer                         , intent(in   ) :: stateFile
  type   (fgsl_file               ), intent(in   ) :: fgslStateFile
  integer(c_size_t                ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`matterDensityEpochal` Convenience function that returns the matter density at the specified epoch. Must have the following interface:

```
 double precision function myImplementationMatterDensityEpochal(self,time           , &
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationMatterDensityEpochal
```

`hubbleParameterRateOfChange` Returns the rate of change of the Hubble parameter at the requested cosmological time, `time`, or expansion factor, `expansionFactor`. Must have the following interface:

```
 double precision function myImplementationHubbleParameterRateOfChange(self,time,&
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationHubbleParameterRateOfChange
```

`distanceLuminosity` Return the luminosity distance to the given cosmic `time`. Must have the following interface:

```
 double precision function myImplementationDistanceLuminosity(self,time)
  class           (cosmologyFunctionsClass), intent(inout) :: self
  double precision                         , intent(in   ) :: time
 end double precision function myImplementationDistanceLuminosity
```

`dominationEpochMatter` Compute the epoch at which matter dominates over other forms of energy by a given factor. Must have the following interface:

```
 double precision function myImplementationDominationEpochMatter(self,dominateFactor)
  class           (cosmologyFunctionsClass), intent(inout) :: self
  double precision                         , intent(in   ) :: dominateFactor
 end double precision function myImplementationDominationEpochMatter
```

`distanceComoving` Return the comoving distance to the given cosmic `time`. Must have the following interface:

```
 double precision function myImplementationDistanceComoving(self,time)
  class           (cosmologyFunctionsClass), intent(inout) :: self
  double precision                         , intent(in   ) :: time
 end double precision function myImplementationDistanceComoving
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(cosmologyFunctionsClass), intent(inout) :: self
  class(cosmologyFunctionsClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`epochTime` Convenience function that returns the time corresponding to an epoch specified by time or expansion factor. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationEpochTime(self,time           , &
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                  , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationEpochTime
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (cosmologyFunctionsClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`timeAtDistanceComoving` Return the cosmic time corresponding to the given `comovingDistance`. Must have the following interface:

```
double precision function myImplementationTimeAtDistanceComoving(self,comovingDistance)
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: comovingDistance
end double precision function myImplementationTimeAtDistanceComoving
```

`equalityEpochMatterCurvature` Return the epoch of matter-curvature magnitude equality (either expansion factor or cosmic time). Must have the following interface:

```
double precision function myImplementationEqualityEpochMatterCurvature(self,requestType&
&  )
 class  (cosmologyFunctionsClass), intent(inout)           :: self
 integer                         , intent(in   ), optional :: requestType
end double precision function myImplementationEqualityEpochMatterCurvature
```

`expansionRate` Returns the cosmological expansion rate, $\dot{a}/a$ at expansion factor `expansionFactor`. Must have the following interface:

```
double precision function myImplementationExpansionRate(self,expansionFactor)
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: expansionFactor
end double precision function myImplementationExpansionRate
```

`expansionFactorFromRedshift` Returns expansion factor given a redshift. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationExpansionFactorFromRedshift(self,redshift)
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: redshift
end double precision function myImplementationExpansionFactorFromRedshift
```

`timeBigCrunch` Return the cosmological age at Big Crunch (or a negative value if no Big Crunch occurs). Must have the following interface:

```
double precision function myImplementationTimeBigCrunch(self)
 class(cosmologyFunctionsClass), intent(inout) :: self
end double precision function myImplementationTimeBigCrunch
```

`distanceAngular` Return the angular diameter distance to the given cosmic `time`. Must have the following interface:

```
double precision function myImplementationDistanceAngular(self,time)
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: time
end double precision function myImplementationDistanceAngular
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(cosmologyFunctionsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`densityScalingEarlyTime` Compute the scaling of density with expansion factor at early times in the universe. Must have the following interface:

```
subroutine myImplementationDensityScalingEarlyTime(self,dominateFactor,densityPower  , &
&  expansionFactorDominant,OmegaDominant)
 class           (cosmologyFunctionsClass), intent(inout)           :: self
 double precision                         , intent(in   )           :: dominateFactor
 double precision                         , intent(  out)           :: densityPower, &
&  expansionFactorDominant
 double precision                         , intent(  out), optional :: OmegaDominant
end subroutine myImplementationDensityScalingEarlyTime
```

`omegaMatterEpochal` Return the matter density parameter at expansion factor `expansionFactor`. Must have the following interface:

```
double precision function myImplementationOmegaMatterEpochal(self,time  , &
&  expansionFactor,collapsingPhase)
 class           (cosmologyFunctionsClass), intent(inout)           :: self
 double precision                         , intent(in   ), optional :: time, &
&  expansionFactor
 logical                                  , intent(in   ), optional :: collapsingPhase
end double precision function myImplementationOmegaMatterEpochal
```

`comovingVolumeElementRedshift` Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}z = r_\mathrm{c}^2(t)\mathrm{c}H^{-1}(t)$ (where r_c is the comoving distance to time t and $H(t)$ is the Hubble parameter at that time) for unit solid angle at the specified `time`. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationComovingVolumeElementRedshift(self,time)
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: time
end double precision function myImplementationComovingVolumeElementRedshift
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (cosmologyFunctionsClass), intent(inout)           :: self
 logical                         , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`exponentDarkEnergy` HASH(0x1fea6a0) Must have the following interface:

```
double precision function myImplementationExponentDarkEnergy(self,time, expansionFactor&
&  )
 class           (cosmologyFunctionsClass), intent(inout)           :: self
```

```
  double precision                          , intent(in   ), optional :: time, &
&  expansionFactor
 end double precision function myImplementationExponentDarkEnergy
```

`omegaMatterRateOfChange` Return the rate of change of the matter density parameter at expansion factor `expansionFactor`. Must have the following interface:

```
 double precision function myImplementationOmegaMatterRateOfChange(self,time  , &
&  expansionFactor,collapsingPhase)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                          , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                   , intent(in   ), optional :: collapsingPhase
 end double precision function myImplementationOmegaMatterRateOfChange
```

`epochValidate` Check the given cosmic epoch is valid (aborting otherwise) and, optionally, return time or expansion factor associated with the epoch. Must have the following interface:

```
 subroutine myImplementationEpochValidate(self,timeIn,expansionFactorIn,collapsingIn,&
&  timeOut,expansionFactorOut,collapsingOut)
  class           (cosmologyFunctionsClass), intent(inout)           :: self
  double precision                          , intent(in   ), optional :: timeIn
  double precision                          , intent(in   ), optional :: &
&  expansionFactorIn
  logical                                   , intent(in   ), optional :: collapsingIn
  double precision                          , intent(  out), optional :: timeOut
  double precision                          , intent(  out), optional :: &
&  expansionFactorOut
  logical                                   , intent(  out), optional :: collapsingOut
 end subroutine myImplementationEpochValidate
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(cosmologyFunctionsClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (cosmologyFunctionsClass)                          , intent(inout) :: self
  type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`redshiftFromExpansionFactor` Returns redshift for a given expansion factor. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationRedshiftFromExpansionFactor(self,&
&  expansionFactor)
```

```
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: expansionFactor
end double precision function myImplementationRedshiftFromExpansionFactor
```

`comovingVolumeElementTime` Returns the differential comoving volume element $\mathrm{d}V/\mathrm{d}t = r_\mathrm{c}^2(t)ca(t)$ (where r_c is the comoving distance to time t and $a(t)$ is the expansion at that time) for unit solid angle at the specified `time`. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationComovingVolumeElementTime(self,time)
 class           (cosmologyFunctionsClass), intent(inout) :: self
 double precision                         , intent(in   ) :: time
end double precision function myImplementationComovingVolumeElementTime
```

Existing implementations are:

`cosmologyFunctionsMatterLambda` Cosmological relations are computed assuming a universe that contains only matter and a cosmological constant. See §12.4.1.

`cosmologyFunctionsMatterDarkEnergy` Cosmological relations are computed assuming a universe that contains only matter and dark energy with an equation of state $w(a) = w_0 + w_1 a(1-a)$. See §12.4.2.

`cosmologyFunctionsStaticUniverse` A cosmology functions class for static universes. Intended for testing purposes. Time is arbitrary (as there is no Big Bang), and expansion factor is fixed at 1. Attempts to compute time from expansion factor will cause fatal errors. Expansion rates and the Hubble constant are set to zero.

Cosmological Parameters

Additional implementations for cosmological parameters are added using the `cosmologyParameters` class. The implementation should be placed in a file containing the directive:

```
!# <cosmologyParameters name="cosmologyParametersMyImplementation">
!# <description>A short description of the implementation.</description>
!# </cosmologyParameters>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `cosmologyParameters-MyImplementation`. The file *must* define a type that extends the `cosmologyParametersClass` class (or extends another type which is itself an extension of the `cosmologyParametersClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`HubbleConstant` Return the Hubble constant at the present day. The optional `units` argument specifies if the return value should be in units of km/s/Mpc (hubbleUnitsStandard), Gyr^{-1} (hubbleUnitsTime), or 100 km/s/Mpc (hubbleUnitsLittleH). Must have the following interface:

```
double precision function myImplementationHubbleConstant(self,units)
 class  (cosmologyParametersClass), intent(inout)           :: self
 integer                          , intent(in   ), optional :: units
end double precision function myImplementationHubbleConstant
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(cosmologyParametersClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`temperatureCMB` Return the temperature of the cosmic microwave background radiation (in units of Kelvin) at the present day. Must have the following interface:

```
double precision function myImplementationTemperatureCMB(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationTemperatureCMB
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (cosmologyParametersClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (cosmologyParametersClass), intent(inout)           :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`OmegaCurvature` Return the cosmological curvature density in units of the critical density at the present day. Must have the following interface:

```
double precision function myImplementationOmegaCurvature(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationOmegaCurvature
```

`OmegaBaryon` Return the cosmological baryon density in units of the critical density at the present day. Must have the following interface:

```
double precision function myImplementationOmegaBaryon(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationOmegaBaryon
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(cosmologyParametersClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`densityCritical` Return the critical density at the present day in units of $M_\odot/\mathrm{Mpc}^3$. Must have the following interface:

```
double precision function myImplementationDensityCritical(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationDensityCritical
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (cosmologyParametersClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`OmegaDarkEnergy` Return the cosmological dark energy density in units of the critical density at the present day. Must have the following interface:

```
double precision function myImplementationOmegaDarkEnergy(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationOmegaDarkEnergy
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (cosmologyParametersClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`OmegaRadiation` Return the cosmological radiation density in units of the critical density at the present day. Must have the following interface:

```
double precision function myImplementationOmegaRadiation(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationOmegaRadiation
```

`OmegaMatter` Return the cosmological matter density in units of the critical density at the present day. Must have the following interface:

```
double precision function myImplementationOmegaMatter(self)
 class(cosmologyParametersClass), intent(inout) :: self
end double precision function myImplementationOmegaMatter
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(cosmologyParametersClass), intent(inout) :: self
 class(cosmologyParametersClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (cosmologyParametersClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`cosmologyParametersSimple` Provides basic cosmological parameters: $(H_0, \Omega_\mathrm{M}, \Omega_\Lambda, \Omega_\mathrm{b}, T_\mathrm{CMB})$. Also provides derived quantities $(\Omega_\mathrm{K}, \Omega_\mathrm{r}, \rho_\mathrm{crit})$.

Critical Overdensity

Additional implementations for critical overdensity are added using the `criticalOverdensity` class. The implementation should be placed in a file containing the directive:

```
!# <criticalOverdensity name="criticalOverdensityMyImplementation">
!# <description>A short description of the implementation.</description>
!# </criticalOverdensity>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `criticalOverdensity-MyImplementation`. The file *must* define a type that extends the `criticalOverdensityClass` class (or extends another type which is itself an extension of the `criticalOverdensityClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`timeOfCollapse` Returns the time of collapse for a perturbation of linear theory overdensity `criticalOverdensity`. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationTimeOfCollapse(self,criticalOverdensity,mass,&
&  node)
  class           (criticalOverdensityClass), intent(inout)                  :: self
  double precision                          , intent(in   )                  :: &
&  criticalOverdensity
  double precision                          , intent(in   ), optional        :: mass
  type            (treeNode                ), intent(inout), optional, target :: node
 end double precision function myImplementationTimeOfCollapse
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (criticalOverdensityClass), intent(inout)          :: self
  logical                          , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (criticalOverdensityClass), intent(inout)          :: self
 type   (inputParameters         ), intent(inout)          :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(criticalOverdensityClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`value` Return the critical overdensity at the given time and mass. Must have the following interface:

```
 double precision function myImplementationValue(self,time      , expansionFactor,&
&  collapsing,mass,node)
  class           (criticalOverdensityClass), intent(inout)           :: self
  double precision                          , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                   , intent(in   ), optional :: collapsing
  double precision                          , intent(in   ), optional :: mass
  type            (treeNode                ), intent(inout), optional :: node
 end double precision function myImplementationValue
```

`isMassDependent` Return true if the critical overdensity is dependent on the mass of the halo. Must have the following interface:

```
logical function myImplementationIsMassDependent(self)
 class(criticalOverdensityClass), intent(inout) :: self
end logical function myImplementationIsMassDependent
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (criticalOverdensityClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`collapsingMass` Return the mass scale just collapsing at the given cosmic time. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationCollapsingMass(self,time      , &
&  expansionFactor,collapsing,node)
  class           (criticalOverdensityClass), intent(inout)                  :: self
  double precision                          , intent(in   ), optional        :: time, &
&  expansionFactor
  logical                                   , intent(in   ), optional        :: &
&  collapsing
  type            (treeNode                ), intent(inout), optional, target :: node
 end double precision function myImplementationCollapsingMass
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (criticalOverdensityClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`gradientTime` Return the derivative with respect to time of the linear theory critical overdensity for collapse at the given cosmic time. Must have the following interface:

```
double precision function myImplementationGradientTime(self,time      , expansionFactor&
&  ,collapsing,mass,node)
 class           (criticalOverdensityClass), intent(inout)           :: self
 double precision                          , intent(in   ), optional :: time, &
&  expansionFactor
 logical                                   , intent(in   ), optional :: collapsing
 double precision                          , intent(in   ), optional :: mass
 type            (treeNode                ), intent(inout), optional :: node
end double precision function myImplementationGradientTime
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(criticalOverdensityClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(criticalOverdensityClass), intent(inout) :: self
 class(criticalOverdensityClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (criticalOverdensityClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`gradientMass` Return the derivative with respect to mass of the linear theory critical overdensity for collapse at the given cosmic time. Must have the following interface:

```
double precision function myImplementationGradientMass(self,time      , expansionFactor&
&  ,collapsing,mass,node)
 class           (criticalOverdensityClass), intent(inout)           :: self
```

```
      double precision                            , intent(in   ), optional :: time, &
     &  expansionFactor
      logical                                     , intent(in   ), optional :: collapsing
      double precision                            , intent(in   ), optional :: mass
      type            (treeNode                  ), intent(inout), optional :: node
     end double precision function myImplementationGradientMass
```

Existing implementations are:

`criticalOverdensityEnvironmental` The critical overdensity is given by some other critical overdensity class multiplied some environment-dependent factor.

`criticalOverdensitySphericalCollapseMatterLambda` Critical overdensity for collapse based on the spherical collapse in a matter plus cosmological constant universe (see, for example, Percival 2005).

`criticalOverdensitySphericalCollapseMatterDE` Critical overdensity for collapse based on the spherical collapse in a matter plus dark energy universe.

`criticalOverdensityKitayamaSuto1996` Provides a critical overdensity class based on the fitting functions of Kitayama and Suto [1996], and is therefore valid only for flat cosmological models.

`criticalOverdensityBarkana2001WDM` Provides a critical overdensity for collapse based on the warm dark matter (WDM) modifier of Barkana et al. [2001] applied to some other critical overdensity class.

`criticalOverdensityFixed` The critical overdensity is set to a fixed number divided by the linear growth factor.

`criticalOverdensityPeakBackgroundSplit` The ciritical overdensity is given by some other critical overdensity class offset by the halo envinronmental overdensity.

Dark matter halo biases.

Additional implementations for dark matter halo biases. are added using the `darkMatterHaloBias` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterHaloBias name="darkMatterHaloBiasMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterHaloBias>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterHaloBiasMyImplementation`. The file *must* define a type that extends the `darkMatterHaloBiasClass` class (or extends another type which is itself an extension of the `darkMatterHaloBiasClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterHaloBiasClass), intent(inout)           :: self
  logical                         , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterHaloBiasClass), intent(inout)           :: self
 type   (inputParameters        ), intent(inout)           :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterHaloBiasClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloBiasClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterHaloBiasClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`biasByMass` Returns the bias of a halo specified by a mass (in $M_\odot$) and time (in Gyr). Must have the following interface:

```
double precision function myImplementationBiasByMass(self,mass, time)
 class           (darkMatterHaloBiasClass), intent(inout) :: self
 double precision                         , intent(in   ) :: mass, time
end double precision function myImplementationBiasByMass
```

`biasByNode` Returns the bias of the halo in the supplied node. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationBiasByNode(self,node)
 class(darkMatterHaloBiasClass), intent(inout) :: self
 type (treeNode               ), intent(inout) :: node
end double precision function myImplementationBiasByNode
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterHaloBiasClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterHaloBiasClass), intent(inout) :: self
 class(darkMatterHaloBiasClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloBiasClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`darkMatterHaloBiasPressSchechter` A dark matter halo mass bias class utilizing the Press-Schechter algorithm [Mo and White, 1996].

`darkMatterHaloBiasSheth2001` A dark matter halo mass bias class utilizing the algorithm of Sheth et al. [2001].

`darkMatterHaloBiasTinker2010` A dark matter halo mass bias class utilizing the algorithm of Tinker et al. [2010].

Dark Matter Halo Mass Accretion Histories

Additional implementations for dark matter halo mass accretion histories are added using the `darkMatterHaloMassAccretionH` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterHaloMassAccretionHistory name="darkMatterHaloMassAccretionHistoryMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterHaloMassAccretionHistory>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain

all functions required by the implementation after that line. Function names should begin with `darkMatterHaloMassAccretionHistoryMyImplementation`. The file *must* define a type that extends the `darkMatterHaloMassAccretionHistoryClass` class (or extends another type which is itself an extension of the `darkMatterHaloMassAccretionHistoryClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterHaloMassAccretionHistoryClass), intent(inout)           :: self
  logical                                         , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (darkMatterHaloMassAccretionHistoryClass), intent(inout)           :: self
  type   (inputParameters                         ), intent(inout)           :: &
&  descriptor
  logical                                          , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(darkMatterHaloMassAccretionHistoryClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`time` Returns the time at which the given halo mass was reached. Must have the following interface:

```
 double precision function myImplementationTime(self,node,mass)
  class           (darkMatterHaloMassAccretionHistoryClass), intent(inout) :: self
  type            (treeNode                               ), intent(inout) :: node
  double precision                                         , intent(in   ) :: mass
 end double precision function myImplementationTime
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (darkMatterHaloMassAccretionHistoryClass), intent(inout) :: self
  integer                                         , intent(in   ) :: stateFile
  type   (fgsl_file                               ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterHaloMassAccretionHistoryClass)                          , intent(&
&  inout) :: self
 type     (varying_string                        ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                                 )                          , intent(&
&  in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterHaloMassAccretionHistoryClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterHaloMassAccretionHistoryClass), intent(inout) :: self
 class(darkMatterHaloMassAccretionHistoryClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloMassAccretionHistoryClass), intent(inout) :: self
 integer                                         , intent(in   ) :: stateFile
 type   (fgsl_file                               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`darkMatterHaloMassAccretionHistoryWechsler2002` Dark matter halo mass accretion histories using the Wechsler et al. [2002] algorithm.

`darkMatterHaloMassAccretionHistoryCorrea2015` Dark matter halo mass accretion histories using the Correa et al. [2015] algorithm.

`darkMatterHaloMassAccretionHistoryZhao2009` Dark matter halo mass accretion histories using the Zhao et al. [2009] algorithm.

Dark matter halo mass loss rates.

Additional implementations for dark matter halo mass loss rates. are added using the `darkMatterHaloMassLossRate` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterHaloMassLossRate name="darkMatterHaloMassLossRateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterHaloMassLossRate>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterHaloMassLossRateMyImplementation`. The file *must* define a type that extends the `darkMatterHaloMassLossRateClass` class (or extends another type which is itself an extension of the `darkMatterHaloMassLossRateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterHaloMassLossRateClass), intent(inout)           :: self
  logical                                 , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterHaloMassLossRateClass), intent(inout)           :: self
 type   (inputParameters                ), intent(inout)           :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterHaloMassLossRateClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloMassLossRateClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (darkMatterHaloMassLossRateClass)                          , intent(inout) &
&  :: self
  type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
```

```
 character(len=*                          )                          , intent(in    ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`rate` Returns the rate of mass loss (in $M_\odot$/Gyr) from `node`. Must have the following interface:

```
double precision function myImplementationRate(self,node)
 class(darkMatterHaloMassLossRateClass), intent(inout) :: self
 type (treeNode                       ), intent(inout) :: node
end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterHaloMassLossRateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterHaloMassLossRateClass), intent(inout) :: self
 class(darkMatterHaloMassLossRateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloMassLossRateClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`darkMatterHaloMassLossRateZero` A dark matter halo mass loss rate class which assumes a zero rate of mass loss.

`darkMatterHaloMassLossRateVanDenBosch` A dark matter halo mass loss rate class which uses the prescription of van den Bosch et al. [2005].

Dark Matter Halo Scales

Additional implementations for dark matter halo scales are added using the `darkMatterHaloScale` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterHaloScale name="darkMatterHaloScaleMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterHaloScale>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterHaloScaleMyImplementation`. The file *must* define a type that extends the `darkMatterHaloScaleClass` class (or extends another type which is itself an extension of the `darkMatterHaloScaleClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`virialVelocity` The virial velocity of a dark matter halo Must have the following interface:

```
double precision function myImplementationVirialVelocity(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationVirialVelocity
```

`meanDensityGrowthRate` The growth rate of the mean density of a dark matter halo. Must have the following interface:

```
double precision function myImplementationMeanDensityGrowthRate(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationMeanDensityGrowthRate
```

`virialTemperature` The virial temperature of a dark matter halo Must have the following interface:

```
double precision function myImplementationVirialTemperature(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationVirialTemperature
```

`dynamicalTimescale` The characteristic dynamical timescale of a dark matter halo. Must have the following interface:

```
double precision function myImplementationDynamicalTimescale(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationDynamicalTimescale
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterHaloScaleClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`meanDensity` The mean density of a dark matter halo. Must have the following interface:

```
double precision function myImplementationMeanDensity(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationMeanDensity
```

`virialRadiusGrowthRate` The growth rate of the virial radius of a dark matter halo. Must have the following interface:

```
double precision function myImplementationVirialRadiusGrowthRate(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationVirialRadiusGrowthRate
```

`virialVelocityGrowthRate` The growth rate of the virial velocity of a dark matter halo. Must have the following interface:

```
double precision function myImplementationVirialVelocityGrowthRate(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationVirialVelocityGrowthRate
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterHaloScaleClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (darkMatterHaloScaleClass), intent(inout)           :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterHaloScaleClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`virialRadius` The virial radius of a dark matter halo. Must have the following interface:

```
double precision function myImplementationVirialRadius(self,node)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationVirialRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloScaleClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterHaloScaleClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterHaloScaleClass), intent(inout) :: self
 class(darkMatterHaloScaleClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterHaloScaleClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`virialRadiusGradientLogarithmicMass` The logarithmic gradient of virial radius of a dark matter halo with halo mass at fixed epoch. Must have the following interface:

```
double precision function myImplementationVirialRadiusGradientLogarithmicMass(self,node&
&  )
 class(darkMatterHaloScaleClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationVirialRadiusGradientLogarithmicMass
```

Existing implementations are:

`darkMatterHaloScaleVirialDensityContrastDefinition` Dark matter halo scales derived from virial density contrasts.

Dark Matter Particle

Additional implementations for dark matter particle are added using the `darkMatterParticle` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterParticle name="darkMatterParticleMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterParticle>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterParticleMyImplementation`. The file *must* define a type that extends the `darkMatterParticleClass` class (or extends another type which is itself an extension of the `darkMatterParticleClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (darkMatterParticleClass), intent(inout)          :: self
 logical                         , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterParticleClass), intent(inout)          :: self
 type   (inputParameters        ), intent(inout)          :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterParticleClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterParticleClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterParticleClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterParticleClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterParticleClass), intent(inout) :: self
 class(darkMatterParticleClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterParticleClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`darkMatterParticleCDM` Provides a cold dark matter particle.

`darkMatterParticleWDMThermal` Provides a thermal warm dark matter particle.

Dark Matter Halo Profiles

Additional implementations for dark matter halo profiles are added using the `darkMatterProfile` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterProfile name="darkMatterProfileMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterProfile>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterProfileMyImplementation`. The file *must* define a type that extends the `darkMatterProfileClass` class (or extends another type which is itself an extension of the `darkMatterProfileClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`energy` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}. Must have the following interface:

```
double precision function myImplementationEnergy(self,node)
 class(darkMatterProfileClass), intent(inout) :: self
 type (treeNode              ), intent(inout) :: node
end double precision function myImplementationEnergy
```

`circularVelocity` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationCircularVelocity(self,node,radius)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                        , intent(in   ) :: radius
end double precision function myImplementationCircularVelocity
```

`potential` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationPotential(self,node,radius,status)
 class           (darkMatterProfileClass), intent(inout)           :: self
 type            (treeNode              ), intent(inout), pointer  :: node
 double precision                        , intent(in   )           :: radius
 integer                                 , intent(  out), optional :: status
end double precision function myImplementationPotential
```

`enclosedMass` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationEnclosedMass(self,node,radius)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                        , intent(in   ) :: radius
end double precision function myImplementationEnclosedMass
```

`radiusEnclosingDensity` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot$Mpc^{-3}) in the dark matter profile of `node`. Must have the following interface:

```
double precision function myImplementationRadiusEnclosingDensity(self,node,density)
 class           (darkMatterProfileClass), intent(inout)         :: self
 type            (treeNode              ), intent(inout), target :: node
 double precision                        , intent(in   )         :: density
end double precision function myImplementationRadiusEnclosingDensity
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterProfileClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`radiusFromSpecificAngularMomentum` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc. Must have the following interface:

```
 double precision function myImplementationRadiusFromSpecificAngularMomentum(self,node,&
&  specificAngularMomentum)
  class           (darkMatterProfileClass), intent(inout)          :: self
  type            (treeNode              ), intent(inout), pointer :: node
  double precision                         , intent(in   )          :: &
&  specificAngularMomentum
 end double precision function myImplementationRadiusFromSpecificAngularMomentum
```

`freefallRadius` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`. Must have the following interface:

```
double precision function myImplementationFreefallRadius(self,node,time)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                         , intent(in   ) :: time
end double precision function myImplementationFreefallRadius
```

`freeFallRadiusIncreaseRate` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`. Must have the following interface:

```
double precision function myImplementationFreeFallRadiusIncreaseRate(self,node,time)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                         , intent(in   ) :: time
end double precision function myImplementationFreeFallRadiusIncreaseRate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterProfileClass), intent(inout)           :: self
  logical                        , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterProfileClass), intent(inout)           :: self
 type   (inputParameters       ), intent(inout)           :: descriptor
 logical                        , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterProfileClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterProfileClass)                          , intent(inout) :: self
 type     (varying_string        ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`energyGrowthRate` Return the rate of change of total energy for the given `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}. Must have the following interface:

```
double precision function myImplementationEnergyGrowthRate(self,node)
 class(darkMatterProfileClass), intent(inout) :: self
 type (treeNode              ), intent(inout) :: node
end double precision function myImplementationEnergyGrowthRate
```

`circularVelocityMaximum` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`. Must have the following interface:

```
double precision function myImplementationCircularVelocityMaximum(self,node)
 class(darkMatterProfileClass), intent(inout) :: self
 type (treeNode              ), intent(inout) :: node
end double precision function myImplementationCircularVelocityMaximum
```

`density` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationDensity(self,node,radius)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                        , intent(in   ) :: radius
end double precision function myImplementationDensity
```

`rotationNormalization` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$ Must have the following interface:

```
double precision function myImplementationRotationNormalization(self,node)
 class(darkMatterProfileClass), intent(inout) :: self
 type (treeNode              ), intent(inout) :: node
end double precision function myImplementationRotationNormalization
```

`radiusEnclosingMass` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationRadiusEnclosingMass(self,node,mass)
 class           (darkMatterProfileClass), intent(inout)         :: self
 type            (treeNode              ), intent(inout), target :: node
 double precision                         , intent(in   )         :: mass
end double precision function myImplementationRadiusEnclosingMass
```

`radialVelocityDispersion` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationRadialVelocityDispersion(self,node,radius)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                         , intent(in   ) :: radius
end double precision function myImplementationRadialVelocityDispersion
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterProfileClass), intent(inout) :: self
 class(darkMatterProfileClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`densityLogSlope` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationDensityLogSlope(self,node,radius)
 class           (darkMatterProfileClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                         , intent(in   ) :: radius
end double precision function myImplementationDensityLogSlope
```

`kSpace` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}). Must have the following interface:

```
double precision function myImplementationKSpace(self,node,wavenumber)
 class           (darkMatterProfileClass), intent(inout)         :: self
 type            (treeNode              ), intent(inout), target :: node
 double precision                         , intent(in   )         :: wavenumber
end double precision function myImplementationKSpace
```

`radialMoment` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc). Must have the following interface:

```
 double precision function myImplementationRadialMoment(self,node,moment,radiusMinimum, &
&  radiusMaximum)
  class           (darkMatterProfileClass), intent(inout)          :: self
  type            (treeNode              ), intent(inout)          :: node
  double precision                         , intent(in   )          :: moment
  double precision                         , intent(in   ), optional :: radiusMinimum, &
&  radiusMaximum
 end double precision function myImplementationRadialMoment
```

Existing implementations are:

`darkMatterProfileDarkMatterOnly` An implementation of non-dark-matter-only dark matter halo profiles which are unchanged from their dark-matter-only counterpart.

`darkMatterProfileAdiabaticGnedin2004` AdiabaticGnedin2004 dark matter halo profiles.

Dark Matter Profile Concentrations

Additional implementations for dark matter profile concentrations are added using the `darkMatterProfileConcentration` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterProfileConcentration name="darkMatterProfileConcentrationMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterProfileConcentration>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterProfileConcentrationMyImplementation`. The file *must* define a type that extends the `darkMatterProfileConcentrationClass` class (or extends another type which is itself an extension of the `darkMatterProfileConcentrationClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`concentration` Returns the concentration parameter for the given `node`. Must have the following interface:

```
double precision function myImplementationConcentration(self,node)
 class(darkMatterProfileConcentrationClass), intent(inout)         :: self
 type (treeNode                           ), intent(inout), target :: node
end double precision function myImplementationConcentration
```

`concentrationMean` Returns the mean concentration parameter for a `node` of the given mass. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationConcentrationMean(self,node)
 class(darkMatterProfileConcentrationClass), intent(inout)         :: self
 type (treeNode                           ), intent(inout), target :: node
end double precision function myImplementationConcentrationMean
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterProfileConcentrationClass), intent(inout)          :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterProfileConcentrationClass), intent(inout)          :: self
 type   (inputParameters                    ), intent(inout)          :: descriptor
 logical                                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterProfileConcentrationClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileConcentrationClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterProfileConcentrationClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterProfileConcentrationClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterProfileConcentrationClass), intent(inout) :: self
 class(darkMatterProfileConcentrationClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`densityContrastDefinition` Returns a `virialDensityContrast` object describing the virial density contrast used to define this concentration. Must have the following interface:

```
class(virialDensityContrastClass) function myImplementationDensityContrastDefinition(&
&  self)
 class(darkMatterProfileConcentrationClass), intent(inout) :: self
end class(virialDensityContrastClass) function &
&  myImplementationDensityContrastDefinition
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileConcentrationClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`darkMatterProfileDMODefinition` Returns a `darkMatterProfileDMO` object describing the dark matter density profile used to define this concentration. Must have the following interface:

```
class(darkMatterProfileDMOClass) function &
&  myImplementationDarkMatterProfileDMODefinition(self)
 class(darkMatterProfileConcentrationClass), intent(inout) :: self
end class(darkMatterProfileDMOClass) function &
&  myImplementationDarkMatterProfileDMODefinition
```

Existing implementations are:

`darkMatterProfileConcentrationDuttonMaccio2014` Dark matter halo concentrations are computed using the algorithm of Dutton and Macciò [2014]. See §12.11.3.

`darkMatterProfileConcentrationWDM` Dark matter halo concentrations are computed using the modifier of Schneider et al. [2012].

`darkMatterProfileConcentrationCorrea2015` Dark matter halo concentrations are computed using the algorithm of Correa et al. [2015].

`darkMatterProfileConcentrationKlypin2015` Dark matter halo concentrations are computed using the algorithm of Klypin et al. [2014].

`darkMatterProfileConcentrationMunozCuartas2011` Dark matter halo concentrations are computed using the algorithm of Muñoz-Cuartas et al. [2011]. See §12.11.3.

`darkMatterProfileConcentrationDiemerKravtsov2014` Dark matter halo concentrations are computed using the algorithm of Diemer and Kravtsov [2014]. See §12.11.3.

`darkMatterProfileConcentrationSchneider2015` Dark matter halo concentrations are computed using the algorithm of Schneider [2015]. See §12.11.3.

`darkMatterProfileConcentrationPrada2011` Dark matter halo concentrations are computed using the algorithm of Prada et al. [2011]. See §12.11.3.

`darkMatterProfileConcentrationBullock2001` Dark matter halo concentrations are computed using the algorithm of Bullock et al. [2001].

`darkMatterProfileConcentrationNFW1996` Dark matter halo concentrations are computed using the algorithm of Navarro et al. [1996]. See §12.11.3.

`darkMatterProfileConcentrationZhao2009` Dark matter halo concentrations are computed using the algorithm of Zhao et al. [2009]. See §12.11.3.

`darkMatterProfileConcentrationGao2008` Dark matter halo concentrations are computed using the algorithm of Gao et al. [2008]. See §12.11.3.

`darkMatterProfileConcentrationLudlow2016Fit` Dark matter halo concentrations are computed using the fitting function of Ludlow et al. [2016].

Dark Matter Halo Profiles

Additional implementations for dark matter halo profiles are added using the `darkMatterProfileDMO` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterProfileDMO name="darkMatterProfileDMOMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterProfileDMO>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterProfileDMOMyImplementation`. The file *must* define a type that extends the `darkMatterProfileDMOClass` class (or extends another type which is itself an extension of the `darkMatterProfileDMOClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`energy` Return the total energy for the given `node` in units of $M_\odot$ km^2 s^{-2}. Must have the following interface:

```
double precision function myImplementationEnergy(self,node)
 class(darkMatterProfileDMOClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationEnergy
```

`circularVelocity` Returns the circular velocity (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationCircularVelocity(self,node,radius)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                            , intent(in   ) :: radius
end double precision function myImplementationCircularVelocity
```

`potential` Returns the gravitational potential (in (km/s)^2) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationPotential(self,node,radius,status)
 class           (darkMatterProfileDMOClass), intent(inout)           :: self
 type            (treeNode                 ), intent(inout), pointer  :: node
 double precision                           , intent(in   )           :: radius
 integer                                    , intent(  out), optional :: status
end double precision function myImplementationPotential
```

`enclosedMass` Returns the enclosed mass (in $M_\odot$) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationEnclosedMass(self,node,radius)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: radius
end double precision function myImplementationEnclosedMass
```

`radiusEnclosingDensity` Returns the radius (in Mpc) enclosing a given density threshold (in $M_\odot \mathrm{Mpc}^{-3}$) in the dark matter profile of `node`. Must have the following interface:

```
double precision function myImplementationRadiusEnclosingDensity(self,node,density)
 class           (darkMatterProfileDMOClass), intent(inout)         :: self
 type            (treeNode                 ), intent(inout), target :: node
 double precision                           , intent(in   )         :: density
end double precision function myImplementationRadiusEnclosingDensity
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterProfileDMOClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`radiusFromSpecificAngularMomentum` Returns the radius (in Mpc) in the dark matter profile of `node` at which the specific angular momentum of a circular orbit equals `specificAngularMomentum` (specified in units of km s^{-1} Mpc. Must have the following interface:

```
double precision function myImplementationRadiusFromSpecificAngularMomentum(self,node,&
&  specificAngularMomentum)
 class           (darkMatterProfileDMOClass), intent(inout)          :: self
 type            (treeNode                 ), intent(inout), pointer :: node
 double precision                           , intent(in   )          :: &
&  specificAngularMomentum
 end double precision function myImplementationRadiusFromSpecificAngularMomentum
```

`freefallRadius` Returns the freefall radius (in Mpc) corresponding to the given `time` (in Gyr) in `node`. Must have the following interface:

```
double precision function myImplementationFreefallRadius(self,node,time)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: time
end double precision function myImplementationFreefallRadius
```

`freeFallRadiusIncreaseRate` Returns the rate of increase of the freefall radius (in Mpc/Gyr) corresponding to the given `time` (in Gyr) in `node`. Must have the following interface:

```
double precision function myImplementationFreeFallRadiusIncreaseRate(self,node,time)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: time
end double precision function myImplementationFreeFallRadiusIncreaseRate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (darkMatterProfileDMOClass), intent(inout)           :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterProfileDMOClass), intent(inout)           :: self
 type   (inputParameters          ), intent(inout)           :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterProfileDMOClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileDMOClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterProfileDMOClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`energyGrowthRate` Returns the rate of chance of the total energy of `node` in units of $M_\odot$ km^2 s^{-2} Gyr^{-1}. Must have the following interface:

```
double precision function myImplementationEnergyGrowthRate(self,node)
 class(darkMatterProfileDMOClass), intent(inout)         :: self
 type (treeNode                 ), intent(inout), target :: node
end double precision function myImplementationEnergyGrowthRate
```

`circularVelocityMaximum` Returns the maximum circular velocity (in km/s) in the dark matter profile of `node`. Must have the following interface:

```
double precision function myImplementationCircularVelocityMaximum(self,node)
 class(darkMatterProfileDMOClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationCircularVelocityMaximum
```

`density` Returns the density (in $M_\odot$ Mpc^{-3}) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationDensity(self,node,radius)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: radius
end double precision function myImplementationDensity
```

`rotationNormalization` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for the given `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$ Must have the following interface:

```
double precision function myImplementationRotationNormalization(self,node)
 class(darkMatterProfileDMOClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationRotationNormalization
```

`radiusEnclosingMass` Returns the radius (in Mpc) enclosing a given mass (in $M_\odot$) in the dark matter profile of `node`. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationRadiusEnclosingMass(self,node,mass)
 class           (darkMatterProfileDMOClass), intent(inout)         :: self
 type            (treeNode                 ), intent(inout), target :: node
 double precision                           , intent(in   )         :: mass
end double precision function myImplementationRadiusEnclosingMass
```

`radialVelocityDispersion` Returns the radial velocity dispersion (in km/s) in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationRadialVelocityDispersion(self,node,radius)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: radius
end double precision function myImplementationRadialVelocityDispersion
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterProfileDMOClass), intent(inout) :: self
 class(darkMatterProfileDMOClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileDMOClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`densityLogSlope` Returns the logarithmic slope of the density profile in the dark matter profile of `node` at the given `radius` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationDensityLogSlope(self,node,radius)
 class           (darkMatterProfileDMOClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 double precision                           , intent(in   ) :: radius
end double precision function myImplementationDensityLogSlope
```

`kSpace` Returns the normalized Fourier space density profile of the dark matter profile of `node` at the given `waveNumber` (given in units of Mpc^{-1}). Must have the following interface:

```
double precision function myImplementationKSpace(self,node,wavenumber)
 class           (darkMatterProfileDMOClass), intent(inout)         :: self
 type            (treeNode                 ), intent(inout), target :: node
 double precision                           , intent(in   )         :: wavenumber
end double precision function myImplementationKSpace
```

`radialMoment` Returns the $\mathtt{m}^{\mathrm{th}}$ radial moment of the dark matter profile of `node` optionally between the given `radiusMinimum` and `radiusMaximum` (given in units of Mpc). Must have the following interface:

```
double precision function myImplementationRadialMoment(self,node,moment,radiusMinimum, &
&  radiusMaximum)
 class           (darkMatterProfileDMOClass), intent(inout)           :: self
 type            (treeNode                 ), intent(inout)           :: node
 double precision                           , intent(in   )           :: moment
 double precision                           , intent(in   ), optional :: radiusMinimum,&
&   radiusMaximum
end double precision function myImplementationRadialMoment
```

Existing implementations are:

`darkMatterProfileDMONFW` Navarro et al. [1997] dark matter halo profiles

`darkMatterProfileDMOTruncated` truncated dark matter halo profiles.

`darkMatterProfileDMOBurkert` Burkert [1995] dark matter halo profiles

`darkMatterProfileDMOTruncatedExponential` exponentially truncated dark matter halo profiles Kazantzidis et al. [2006].

`darkMatterProfileDMOHeated` Heated dark matter halo profiles.

`darkMatterProfileDMOEinasto` "Einasto" dark matter halo profiles

`darkMatterProfileDMOIsothermal` Isothermal dark matter halo profiles

Dark Matter Profile Heating

Additional implementations for dark matter profile heating are added using the `darkMatterProfileHeating` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterProfileHeating name="darkMatterProfileHeatingMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterProfileHeating>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterProfileHeatingMyImplementation`. The file *must* define a type that extends the `darkMatterProfileHeatingClass` class (or extends another type which is itself an extension of the `darkMatterProfileHeatingClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterProfileHeatingClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`specificEnergyGradient` The gradient of the specific energy of heating at the given `radius` in the given `node`. Must have the following interface:

```
double precision function myImplementationSpecificEnergyGradient(self,node,&
&  darkMatterProfileDMO_,radius)
  class           (darkMatterProfileHeatingClass), intent(inout) :: self
  type            (treeNode                     ), intent(inout) :: node
  class           (darkMatterProfileDMOClass    ), intent(inout) :: &
&  darkMatterProfileDMO_
  double precision                                 , intent(in   ) :: radius
end double precision function myImplementationSpecificEnergyGradient
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterProfileHeatingClass), intent(inout)          :: self
  logical                               , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterProfileHeatingClass), intent(inout)           :: self
 type   (inputParameters              ), intent(inout)           :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterProfileHeatingClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileHeatingClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`specificEnergy` The specific energy of heating at the given `radius` in the given `node`. Must have the following interface:

```
 double precision function myImplementationSpecificEnergy(self,node,&
&  darkMatterProfileDMO_,radius)
  class           (darkMatterProfileHeatingClass), intent(inout) :: self
  type            (treeNode                     ), intent(inout) :: node
  class           (darkMatterProfileDMOClass    ), intent(inout) :: &
&  darkMatterProfileDMO_
  double precision                                 , intent(in   ) :: radius
 end double precision function myImplementationSpecificEnergy
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (darkMatterProfileHeatingClass)                          , intent(inout) :: &
&  self
  type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterProfileHeatingClass), intent(inout) :: self
 class(darkMatterProfileHeatingClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileHeatingClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`specificEnergyIsEverywhereZero` Returns true if the specific energy is zero everywhere in the given `node`. Must have the following interface:

```
logical function myImplementationSpecificEnergyIsEverywhereZero(self,node,&
&  darkMatterProfileDMO_)
 class(darkMatterProfileHeatingClass), intent(inout) :: self
 type (treeNode                     ), intent(inout) :: node
 class(darkMatterProfileDMOClass    ), intent(inout) :: darkMatterProfileDMO_
end logical function myImplementationSpecificEnergyIsEverywhereZero
```

Existing implementations are:

`darkMatterProfileHeatingSummation` A dark matter profile heating model which sums over other heat sources.

`darkMatterProfileHeatingTwoBodyRelaxation` A dark matter profile heating model which computes heating due to two-body relaxation.

`darkMatterProfileHeatingNull` A dark matter profile heating model in which the heating is always zero.

`darkMatterProfileHeatingTidal` A dark matter profile heating model which accounts for heating due to tidal shocking.

Dark Matter Profile Scale Radii

Additional implementations for dark matter profile scale radii are added using the `darkMatterProfileScaleRadius` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterProfileScaleRadius name="darkMatterProfileScaleRadiusMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterProfileScaleRadius>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterProfile-ScaleRadiusMyImplementation`. The file *must* define a type that extends the `darkMatterProfileScaleRadiusClass` class (or extends another type which is itself an extension of the `darkMatterProfileScaleRadiusClass`

class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterProfileScaleRadiusClass), intent(inout)          :: self
  logical                                   , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (darkMatterProfileScaleRadiusClass), intent(inout)          :: self
 type   (inputParameters                  ), intent(inout)          :: descriptor
 logical                                   , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(darkMatterProfileScaleRadiusClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`radius` Returns the scale radius for the given `node`. Must have the following interface:

```
double precision function myImplementationRadius(self,node)
 class(darkMatterProfileScaleRadiusClass), intent(inout)         :: self
 type (treeNode                          ), intent(inout), target :: node
end double precision function myImplementationRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileScaleRadiusClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterProfileScaleRadiusClass)                          , intent(inout)&
&   :: self
```

```
  type     (varying_string                  ), allocatable, dimension(:), intent(inout)&
&   :: allowedParameters
  character(len=*                           )                           , intent(in   )&
&   :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterProfileScaleRadiusClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterProfileScaleRadiusClass), intent(inout) :: self
 class(darkMatterProfileScaleRadiusClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileScaleRadiusClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`darkMatterProfileScaleRadiusZero` Dark matter halo scale radii class in which are assumed to be zero.

`darkMatterProfileScaleRadiusBinary` A dark matter halo profile scale radii class which switches between two methods based on a filter.

`darkMatterProfileScaleRadiusLudlow2014` Dark matter halo scale radii are computed using the algorithm of Ludlow et al. [2014].

`darkMatterProfileScaleRadiusConcentration` Dark matter halo scale radii are computed from the concentration.

`darkMatterProfileScaleRadiusLudlow2016` Dark matter halo scale radii are computed using the algorithm of Ludlow et al. [2016]. While Ludlow et al. [2016] used $\Delta = 200\rho_{\rm crit}$ to define halos, their model actually predicts the scale radius, r_{-2}, rather than the concentration. Therefore, here we report that the Ludlow et al. [2016] concentrations are defined using the model's own virial density contrast definition — this ensures that the predicted scale radii are applied directly to model halos.

Dark Matter Profile Shapes

Additional implementations for dark matter profile shapes are added using the `darkMatterProfileShape` class. The implementation should be placed in a file containing the directive:

```
!# <darkMatterProfileShape name="darkMatterProfileShapeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </darkMatterProfileShape>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `darkMatterProfileShapeMyImplementation`. The file *must* define a type that extends the `darkMatterProfileShapeClass` class (or extends another type which is itself an extension of the `darkMatterProfileShapeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (darkMatterProfileShapeClass), intent(inout)           :: self
  logical                             , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (darkMatterProfileShapeClass), intent(inout)           :: self
  type   (inputParameters            ), intent(inout)           :: descriptor
  logical                             , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(darkMatterProfileShapeClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (darkMatterProfileShapeClass), intent(inout) :: self
  integer                             , intent(in   ) :: stateFile
  type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
  integer(c_size_t                   ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (darkMatterProfileShapeClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(darkMatterProfileShapeClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(darkMatterProfileShapeClass), intent(inout) :: self
 class(darkMatterProfileShapeClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`shape` Returns the shape parameter for the given `node`. Must have the following interface:

```
double precision function myImplementationShape(self,node)
 class(darkMatterProfileShapeClass), intent(inout)          :: self
 type (treeNode                   ), intent(inout), pointer :: node
end double precision function myImplementationShape
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (darkMatterProfileShapeClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                   ), intent(in   ) :: fgslStateFile
 integer(c_size_t                    ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`darkMatterProfileShapeGao2008` Dark matter halo shape parameters are computed using the algorithm of Gao et al. [2008].

`darkMatterProfileShapeKlypin2015` Dark matter halo shape parameters are computed using the algorithm of Klypin et al. [2014].

One-dimensional Distribution Functions

Additional implementations for one-dimensional distribution functions are added using the `distributionFunction1D` class. The implementation should be placed in a file containing the directive:

```
!# <distributionFunction1D name="distributionFunction1DMyImplementation">
!# <description>A short description of the implementation.</description>
!# </distributionFunction1D>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `distributionFunction1DMyImplementation`. The file *must* define a type that extends the `distributionFunction1DClass` class (or extends another type which is itself an extension of the `distributionFunction1DClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`minimum` Returns the minimum possible value in the distribution. Must have the following interface:

```
double precision function myImplementationMinimum(self)
 class(distributionFunction1DClass), intent(inout) :: self
end double precision function myImplementationMinimum
```

`maximum` Returns the maximum possible value in the distribution. Must have the following interface:

```
double precision function myImplementationMaximum(self)
 class(distributionFunction1DClass), intent(inout) :: self
end double precision function myImplementationMaximum
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (distributionFunction1DClass), intent(inout)           :: self
 logical                             , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (distributionFunction1DClass), intent(inout)           :: self
 type   (inputParameters            ), intent(inout)           :: descriptor
 logical                             , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(distributionFunction1DClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (distributionFunction1DClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (distributionFunction1DClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`samplerReset` Reset the sampler for the distribution. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationSamplerReset(self)
 class(distributionFunction1DClass), intent(inout) :: self
end subroutine myImplementationSamplerReset
```

`density` Return the probability density at `x`. Must have the following interface:

```
double precision function myImplementationDensity(self,x)
 class           (distributionFunction1DClass), intent(inout) :: self
 double precision                             , intent(in   ) :: x
end double precision function myImplementationDensity
```

`inverse` Return the value of the independent variable corresponding to cumulative probability `p`. Must have the following interface:

```
double precision function myImplementationInverse(self,p)
 class           (distributionFunction1DClass), intent(inout) :: self
 double precision                             , intent(in   ) :: p
end double precision function myImplementationInverse
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(distributionFunction1DClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(distributionFunction1DClass), intent(inout) :: self
 class(distributionFunction1DClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`sample` Return a random deviate from the distribution. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationSample(self,incrementSeed,ompThreadOffset, &
&  mpiRankOffset,randomNumberGenerator)
 class  (distributionFunction1DClass), intent(inout)           :: self
 integer                             , intent(in   ), optional :: incrementSeed
 logical                             , intent(in   ), optional :: ompThreadOffset, &
&  mpiRankOffset
 type   (pseudoRandom               ), intent(inout), optional :: randomNumberGenerator
end double precision function myImplementationSample
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (distributionFunction1DClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`cumulative` Return the cumulative probability at `x`. Must have the following interface:

```
double precision function myImplementationCumulative(self,x)
 class           (distributionFunction1DClass), intent(inout) :: self
 double precision                             , intent(in   ) :: x
end double precision function myImplementationCumulative
```

Existing implementations are:

`distributionFunction1DUniform` A uniform 1D distribution function class.

`distributionFunction1DBeta` A beta 1D distribution function class.

`distributionFunction1DVoight` A 1D distribution function class for Voight profiles.

`distributionFunction1DStudentT` A 1D Student-t distibution function.

`distributionFunction1DPeakBackground` A peakBackground 1D distribution function class.

`distributionFunction1DLogUniform` A 1D distibution function which is uniform in the logarithm of the variable.

`distributionFunction1DNormal` A normal 1D distribution function class.

`distributionFunction1DNegativeExponential` A negative exponential 1D distribution function class.

`distributionFunction1DCauchy` A 1D Cauchy distibution function.

`distributionFunction1DLogNormal` A normal 1D distribution function class.

`distributionFunction1DGamma` A 1D gamma distribution function class.

One-dimensional Discrete Distribution Functions

Additional implementations for one-dimensional discrete distribution functions are added using the `distributionFunctionDis` class. The implementation should be placed in a file containing the directive:

```
!# <distributionFunctionDiscrete1D name="distributionFunctionDiscrete1DMyImplementation">
!# <description>A short description of the implementation.</description>
!# </distributionFunctionDiscrete1D>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `distributionFunctionDiscrete1DMyImplementation`. The file *must* define a type that extends the `distributionFunctionDiscrete1DClass` class (or extends another type which is itself an extension of the `distributionFunctionDiscrete1DClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`minimum` Returns the minimum possible value in the distribution. Must have the following interface:

```
integer function myImplementationMinimum(self)
 class(distributionFunctionDiscrete1DClass), intent(inout) :: self
end integer function myImplementationMinimum
```

`maximum` Returns the maximum possible value in the distribution. Must have the following interface:

```
integer function myImplementationMaximum(self)
 class(distributionFunctionDiscrete1DClass), intent(inout) :: self
end integer function myImplementationMaximum
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (distributionFunctionDiscrete1DClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
& includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (distributionFunctionDiscrete1DClass), intent(inout)           :: self
 type   (inputParameters                    ), intent(inout)           :: descriptor
 logical                                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`massLogarithmic` Return the logarithm of the probability mass at `x`. Must have the following interface:

```
double precision function myImplementationMassLogarithmic(self,x)
 class  (distributionFunctionDiscrete1DClass), intent(inout) :: self
 integer                                     , intent(in   ) :: x
end double precision function myImplementationMassLogarithmic
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(distributionFunctionDiscrete1DClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (distributionFunctionDiscrete1DClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (distributionFunctionDiscrete1DClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`samplerReset` Reset the sampler for the distribution. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationSamplerReset(self)
 class(distributionFunctionDiscrete1DClass), intent(inout) :: self
end subroutine myImplementationSamplerReset
```

`inverse` Return the value of the independent variable corresponding to cumulative probability `p`. Must have the following interface:

```
integer function myImplementationInverse(self,p)
 class           (distributionFunctionDiscrete1DClass), intent(inout) :: self
 double precision                                     , intent(in   ) :: p
end integer function myImplementationInverse
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(distributionFunctionDiscrete1DClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`mass` Return the probability mass at `x`. Must have the following interface:

```
double precision function myImplementationMass(self,x)
 class  (distributionFunctionDiscrete1DClass), intent(inout) :: self
 integer                                     , intent(in   ) :: x
end double precision function myImplementationMass
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(distributionFunctionDiscrete1DClass), intent(inout) :: self
 class(distributionFunctionDiscrete1DClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`sample` Return a random deviate from the distribution. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationSample(self,incrementSeed,ompThreadOffset, &
&  mpiRankOffset,randomNumberGenerator)
 class  (distributionFunctionDiscrete1DClass), intent(inout)           :: self
 integer                                     , intent(in   ), optional :: incrementSeed
 logical                                     , intent(in   ), optional :: &
&  ompThreadOffset, mpiRankOffset
 type   (pseudoRandom                       ), intent(inout), optional :: &
&  randomNumberGenerator
end integer function myImplementationSample
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (distributionFunctionDiscrete1DClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`cumulative` Return the cumulative probability at `x`. Must have the following interface:

```
double precision function myImplementationCumulative(self,x)
 class  (distributionFunctionDiscrete1DClass), intent(inout) :: self
 integer                                     , intent(in   ) :: x
end double precision function myImplementationCumulative
```

Existing implementations are:

`distributionFunctionDiscrete1DNegativeBinomial` A negative binomial 1D discrete distribution function class.

`distributionFunctionDiscrete1DBinomial` A binomial 1D discrete distribution function class.

Evolve Forests Work Share

Additional implementations for evolve forests work share are added using the `evolveForestsWorkShare` class. The implementation should be placed in a file containing the directive:

```
!# <evolveForestsWorkShare name="evolveForestsWorkShareMyImplementation">
!# <description>A short description of the implementation.</description>
!# </evolveForestsWorkShare>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `evolveForestsWorkShareMyImplementation`. The file *must* define a type that extends the `evolveForestsWorkShareClass` class (or extends another type which is itself an extension of the `evolveForestsWorkShareClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`forestNumber` Return the number of the forest to process. Must have the following interface:

```
integer(c_size_t) function myImplementationForestNumber(self,utilizeOpenMPThreads)
 class  (evolveForestsWorkShareClass), intent(inout) :: self
 logical                             , intent(in   ) :: utilizeOpenMPThreads
end integer(c_size_t) function myImplementationForestNumber
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (evolveForestsWorkShareClass), intent(inout)           :: self
 logical                             , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (evolveForestsWorkShareClass), intent(inout)           :: self
 type   (inputParameters            ), intent(inout)           :: descriptor
 logical                             , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(evolveForestsWorkShareClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (evolveForestsWorkShareClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (evolveForestsWorkShareClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`workerID` Return a unique worker ID. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationWorkerID(self,utilizeOpenMPThreads)
 class  (evolveForestsWorkShareClass), intent(inout) :: self
 logical                             , intent(in   ) :: utilizeOpenMPThreads
end integer function myImplementationWorkerID
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(evolveForestsWorkShareClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(evolveForestsWorkShareClass), intent(inout) :: self
 class(evolveForestsWorkShareClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (evolveForestsWorkShareClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`workerCount` Return the count of workers. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationWorkerCount(self,utilizeOpenMPThreads)
 class  (evolveForestsWorkShareClass), intent(inout) :: self
 logical                             , intent(in   ) :: utilizeOpenMPThreads
end integer function myImplementationWorkerCount
```

Existing implementations are:

`evolveForestsWorkShareCyclic` A forest evolution work sharing class in which forests are assigned by cycling through processes.

`evolveForestsWorkShareFCFS` A forest evolution work sharing class in which forests are assigned on a first-come-first-served basis.

`evolveForestsWorkShareStride` A forest evolution work sharing class in which forests are assigned by another work sharing class, but then strided over in steps of a specified size.

Excursion Set Barrier

Additional implementations for excursion set barrier are added using the `excursionSetBarrier` class. The implementation should be placed in a file containing the directive:

```
!# <excursionSetBarrier name="excursionSetBarrierMyImplementation">
!# <description>A short description of the implementation.</description>
!# </excursionSetBarrier>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `excursionSetBarrierMyImplementation`. The file *must* define a type that extends the `excursionSetBarrierClass` class (or extends another type which is itself an extension of the `excursionSetBarrierClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (excursionSetBarrierClass), intent(inout)           :: self
  logical                          , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (excursionSetBarrierClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`barrier` Return the barrier height at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise. Must have the following interface:

```
double precision function myImplementationBarrier(self,variance   , time,node,&
&  rateCompute)
 class           (excursionSetBarrierClass), intent(inout) :: self
 double precision                          , intent(in   ) :: variance, time
 type            (treeNode                ), intent(inout) :: node
 logical                                   , intent(in   ) :: rateCompute
end double precision function myImplementationBarrier
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(excursionSetBarrierClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (excursionSetBarrierClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (excursionSetBarrierClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(excursionSetBarrierClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(excursionSetBarrierClass), intent(inout) :: self
 class(excursionSetBarrierClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`barrierGradient` Return the gradient of the barrier with respect to variance at the given variance and time. The `rateCompute` should be set to `true` if the barrier is being used in a calculation of barrier crossing rates, and to `false` otherwise. Must have the following interface:

```
double precision function myImplementationBarrierGradient(self,variance   , time,node,&
&  rateCompute)
 class           (excursionSetBarrierClass), intent(inout) :: self
 double precision                          , intent(in   ) :: variance, time
 type            (treeNode                ), intent(inout) :: node
 logical                                   , intent(in   ) :: rateCompute
end double precision function myImplementationBarrierGradient
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (excursionSetBarrierClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`excursionSetBarrierLinear` A linear excursion set barrier class.

`excursionSetBarrierCriticalOverdensity` A critical overdensity excursion set barrier class.

`excursionSetBarrierQuadratic` A quadratic excursion set barrier class.

`excursionSetBarrierRemapScale` An excursion set barrier class which remaps another class by multiplying by a constant.

`excursionSetBarrierRemapShethMoTormen` An excursion set barrier class which remaps another class using the Sheth et al. [2001] ellipsoidal collapse parameterization.

Excursion Set First Crossing Statistics

Additional implementations for excursion set first crossing statistics are added using the `excursionSetFirstCrossing` class. The implementation should be placed in a file containing the directive:

```
!# <excursionSetFirstCrossing name="excursionSetFirstCrossingMyImplementation">
!# <description>A short description of the implementation.</description>
!# </excursionSetFirstCrossing>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `excursionSetFirstCrossingMyImplementation`. The file *must* define a type that extends the `excursionSetFirstCrossingClass` class (or extends another type which is itself an extension of the `excursionSetFirstCrossingClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (excursionSetFirstCrossingClass), intent(inout)           :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (excursionSetFirstCrossingClass), intent(inout)           :: self
 type   (inputParameters               ), intent(inout)           :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(excursionSetFirstCrossingClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (excursionSetFirstCrossingClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`probability` Return the probability for a trajectory to make its first crossing of the barrier at the given `variance` and `time`. Must have the following interface:

```
double precision function myImplementationProbability(self,variance, time,node)
 class           (excursionSetFirstCrossingClass), intent(inout) :: self
 double precision                                , intent(in   ) :: variance, time
 type            (treeNode                      ), intent(inout) :: node
end double precision function myImplementationProbability
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (excursionSetFirstCrossingClass)                          , intent(inout) ::&
&   self
 type     (varying_string                ), allocatable, dimension(:), intent(inout) ::&
&   allowedParameters
 character(len=*                         )                          , intent(in   ) ::&
&   sourceName
 end subroutine myImplementationAllowedParameters
```

`coordinatedMPI` Sets the state of coordination under MPI. If set to true then the object can assume that any calculations it performs are being performed identically by all other MPI processes. This permits, for example, coordinated tabulation of results across MPI processes. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationCoordinatedMPI(self,state)
 class  (excursionSetFirstCrossingClass), intent(inout) :: self
 logical                                , intent(in   ) :: state
end subroutine myImplementationCoordinatedMPI
```

`rate` Return the rate of first crossing for excursion sets beginning at the given `variance` and `time` to transition to a first crossing at the given `varianceProgenitor`. Must have the following interface:

```
 double precision function myImplementationRate(self,variance, varianceProgenitor, time,&
&  node)
  class           (excursionSetFirstCrossingClass), intent(inout) :: self
  double precision                                , intent(in   ) :: variance, &
&  varianceProgenitor, time
  type            (treeNode                      ), intent(inout) :: node
 end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(excursionSetFirstCrossingClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(excursionSetFirstCrossingClass), intent(inout) :: self
 class(excursionSetFirstCrossingClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`rateNonCrossing` Return the rate of non-crossing for excursion sets beginning at the given `variance` and `time`. Must have the following interface:

```
double precision function myImplementationRateNonCrossing(self,variance, time,node)
 class           (excursionSetFirstCrossingClass), intent(inout) :: self
 double precision                                , intent(in   ) :: variance, time
 type            (treeNode                      ), intent(inout) :: node
end double precision function myImplementationRateNonCrossing
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (excursionSetFirstCrossingClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`excursionSetFirstCrossingLinearBarrier` An excursion set first crossing statistics class for linear barriers.

`excursionSetFirstCrossingFarahiMidpoint` An excursion set first crossing statistics class using the algorithm of Benson et al. [2012], but using a midpoint method to perform the integrations [Du et al., 2017].

`excursionSetFirstCrossingZhangHui` An excursion set first crossing statistics class utilizing the algorithm of Zhang and Hui [2006].

`excursionSetFirstCrossingFarahi` An excursion set first crossing statistics class using the algorithm of Benson et al. [2012].

`excursionSetFirstCrossingZhangHuiHighOrder` An excursion set first crossing statistics class utilizing a higher order generalization of the algorithm of Zhang and Hui [2006].

Freefall radii.

Additional implementations for freefall radii. are added using the `freefallRadius` class. The implementation should be placed in a file containing the directive:

```
!# <freefallRadius name="freefallRadiusMyImplementation">
!# <description>A short description of the implementation.</description>
!# </freefallRadius>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `freefallRadiusMyImplementation`. The file *must* define a type that extends the `freefallRadiusClass` class (or extends another type which is itself an extension of the `freefallRadiusClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (freefallRadiusClass), intent(inout)           :: self
  logical                     , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (freefallRadiusClass), intent(inout)           :: self
 type   (inputParameters    ), intent(inout)           :: descriptor
 logical                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`radiusGrowthRate` Returns the rate of increase of the freefall radius for gas in the hot atmosphere surrounding the galaxy in `node` in units of Mpc/Gyr. Must have the following interface:

```
double precision function myImplementationRadiusGrowthRate(self,node)
 class(freefallRadiusClass), intent(inout) :: self
 type (treeNode           ), intent(inout) :: node
end double precision function myImplementationRadiusGrowthRate
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(freefallRadiusClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`radius` Returns the freefall radius for gas in the hot atmosphere surrounding the galaxy in `node` in units of Mpc. Must have the following interface:

```
double precision function myImplementationRadius(self,node)
 class(freefallRadiusClass), intent(inout) :: self
 type (treeNode           ), intent(inout) :: node
end double precision function myImplementationRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (freefallRadiusClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (freefallRadiusClass)                            , intent(inout) :: self
 type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*              )                            , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(freefallRadiusClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(freefallRadiusClass), intent(inout) :: self
 class(freefallRadiusClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (freefallRadiusClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`freefallRadiusDarkMatterHalo` A freefall radius class which computes the freefall radius based on the freefall time in the dark matter halo.

Freefall time available.

Additional implementations for freefall time available. are added using the `freefallTimeAvailable` class. The implementation should be placed in a file containing the directive:

```
!# <freefallTimeAvailable name="freefallTimeAvailableMyImplementation">
!# <description>A short description of the implementation.</description>
!# </freefallTimeAvailable>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `freefallTimeAvailableMyImplementation`. The file *must* define a type that extends the `freefallTimeAvailableClass` class (or extends another type which is itself an extension of the `freefallTimeAvailableClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (freefallTimeAvailableClass), intent(inout)          :: self
 logical                            , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (freefallTimeAvailableClass), intent(inout)          :: self
 type   (inputParameters           ), intent(inout)          :: descriptor
 logical                            , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(freefallTimeAvailableClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (freefallTimeAvailableClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (freefallTimeAvailableClass)                          , intent(inout) :: &
&  self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`timeAvailable` Returns the time available for freefall in cooling calculations in `node`. Must have the following interface:

```
double precision function myImplementationTimeAvailable(self,node)
 class(freefallTimeAvailableClass), intent(inout) :: self
 type (treeNode                  ), intent(inout) :: node
end double precision function myImplementationTimeAvailable
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(freefallTimeAvailableClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(freefallTimeAvailableClass), intent(inout) :: self
 class(freefallTimeAvailableClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`timeAvailableIncreaseRate` Returns the rate at which the time available for freefall in cooling calculations increases in `node`. Must have the following interface:

```
double precision function myImplementationTimeAvailableIncreaseRate(self,node)
 class(freefallTimeAvailableClass), intent(inout) :: self
 type (treeNode                  ), intent(inout) :: node
end double precision function myImplementationTimeAvailableIncreaseRate
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (freefallTimeAvailableClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`freefallTimeAvailableHaloFormation` A freefall time available class which computes the freefall time available based on the freefall time in the dark matter halo.

Bar instabilities in galactic disks

Additional implementations for bar instabilities in galactic disks are added using the `galacticDynamicsBarInstability` class. The implementation should be placed in a file containing the directive:

```
!# <galacticDynamicsBarInstability name="galacticDynamicsBarInstabilityMyImplementation">
!# <description>A short description of the implementation.</description>
!# </galacticDynamicsBarInstability>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `galacticDynamicsBarInstabilityMyImplementation`. The file *must* define a type that extends the `galacticDynamicsBarInstabilityClass` class (or extends another type which is itself an extension of the `galacticDynamicsBarInstabilityClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (galacticDynamicsBarInstabilityClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (galacticDynamicsBarInstabilityClass), intent(inout)           :: self
 type   (inputParameters                   ), intent(inout)           :: descriptor
 logical                                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(galacticDynamicsBarInstabilityClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (galacticDynamicsBarInstabilityClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (galacticDynamicsBarInstabilityClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`timescale` Returns a timescale on which the bar instability depletes material from a disk into a pseudo-bulge. A negative value indicates no instability. Also returns the net torque due to any external force causing this instability. Must have the following interface:

```
subroutine myImplementationTimescale(self,node,timescale, externalDrivingSpecificTorque&
&  )
 class           (galacticDynamicsBarInstabilityClass), intent(inout) :: self
 type            (treeNode                           ), intent(inout) :: node
 double precision                                     , intent(  out) :: timescale, &
&  externalDrivingSpecificTorque
 end subroutine myImplementationTimescale
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(galacticDynamicsBarInstabilityClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(galacticDynamicsBarInstabilityClass), intent(inout) :: self
 class(galacticDynamicsBarInstabilityClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (galacticDynamicsBarInstabilityClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`galacticDynamicsBarInstabilityStable` A perfect stability model for galactic disk bar instability.

`galacticDynamicsBarInstabilityEfstathiou1982Tidal` The Efstathiou et al. [1982] model for galactic disk bar instability, but include the effects of tidal forces.

`galacticDynamicsBarInstabilityFixedTimescale` A simple model for galactic disk bar instability in which the timescale is fixed.

`galacticDynamicsBarInstabilityEfstathiou1982` The Efstathiou et al. [1982] model for galactic disk bar instability.

Galactic Filter

Additional implementations for galactic filter are added using the `galacticFilter` class. The implementation should be placed in a file containing the directive:

```
!# <galacticFilter name="galacticFilterMyImplementation">
!# <description>A short description of the implementation.</description>
!# </galacticFilter>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `galacticFilterMyImplementation`. The file *must* define a type that extends the `galacticFilterClass` class (or extends another type which is itself an extension of the `galacticFilterClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`passes` Return true if the given `node` passes the filter. Must have the following interface:

```
logical function myImplementationPasses(self,node)
 class(galacticFilterClass), intent(inout) :: self
 type (treeNode           ), intent(inout) :: node
end logical function myImplementationPasses
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (galacticFilterClass), intent(inout)           :: self
  logical                     , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (galacticFilterClass), intent(inout)           :: self
  type   (inputParameters    ), intent(inout)           :: descriptor
  logical                     , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(galacticFilterClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (galacticFilterClass), intent(inout) :: self
  integer                     , intent(in   ) :: stateFile
  type   (fgsl_file          ), intent(in   ) :: fgslStateFile
  integer(c_size_t           ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (galacticFilterClass)                          , intent(inout) :: self
  type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*              )                          , intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(galacticFilterClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(galacticFilterClass), intent(inout) :: self
 class(galacticFilterClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (galacticFilterClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`galacticFilterSpheroidStellarMass` A galactic high-pass filter for stellar mass. Galaxies with a spheroid stellar mass greater than or equal to a fixed threshold, $M_{\star,0} =$ `[massThreshold]`.

`galacticFilterBasicMass` A high-pass filter for basic mass. Halos with a basic mass mass greater than or equal to a fixed threshold, $M_0 =$ `[massThreshold]`.

`galacticFilterAlways` A galactic filter which always passes. (Used mostly for testing purposes.)

`galacticFilterStarFormationRate` A galactic high-pass filter for star formation rate. Galaxies with a combined disk plus spheroid star formation rate greater than or equal to a mass-dependent threshold. The threshold is given by

$$\log_{10}\left(\frac{\dot{\phi}_\mathrm{t}}{M_\odot\,\mathrm{Gyr}^{-1}}\right) = \alpha_0 + \alpha_1\left(\log_{10} M_\star - \log_{10} M_0\right), \tag{16.3}$$

where $M_0 =$ `[starFormationRateThresholdLogM0]`, $\alpha_0 =$ `[starFormationRateThresholdLogSFR0]`, and $\alpha_1 =$ `[starFormationRateThresholdLogSFR1]`.

`galacticFilterTreeHosted` A filter which passes only nodes that are hosted in a merger tree.

`galacticFilterStellarMassMorphology` A galactic high-pass filter for stellar mass-weighted morphology (i.e. spheroid-to-total ratio). Galaxies with a spheroid-to-total ratio (by stellar mass) greater than or equal to a fixed threshold, $R_{\star,0} =$ `[spheroidToTotalThreshold]`.

`galacticFilterNot` A filter which simply inverts the result of another filter.

`galacticFilterHaloIsolated` A filter which passes only isolated halos.

`galacticFilterAny` A galactic filter class which is the "any" combination of a set of other filters.

`galacticFilterLightcone` A galactic filter on lightcone geometry.

`galacticFilterStellarMass` A galactic high-pass filter for stellar mass. Galaxies with a combined disk plus spheroid stellar mass greater than or equal to a fixed threshold, $M_{\star,0} =$ `[massThreshold]`.

`galacticFilterRootNode` A filter which passes only nodes which are roots of their merger tree.

`galacticFilterNodeMajorMergerRecent` A low-pass filter for time since the last major node merger. Halos with a time of the last major node merger greater than or equal to the current time minus $\Delta t =$ `[timeRecent]` are passed.

`galacticFilterAll` A galactic filter class which is the "all" combination of a set of other filters.

`galacticFilterMainBranch` A filter which passes only main branch halos.

`galacticFilterHaloMass` A high-pass filter for basic mass. Halos with a halo mass greater than or equal to a fixed threshold, $M_0 =$ `[massThreshold]`.

`galacticFilterISMMass` A galactic high-pass filter for ISM mass. Galaxies with a combined disk plus spheroid ISM mass greater than or equal to a fixed threshold, $M_{\rm ISM,0} =$ `[massThreshold]`.

`galacticFilterSurveyGeometry` A filter which passes only nodes that lie within a survey geometry.

`galacticFilterStellarApparentMagnitudes` A galactic low-pass (i.e. bright-pass) filter for stellar apparent magnitudes. Galaxies with apparent magnitude in each band, i, less than or equal to a fixed threshold, $m_{0,i} =$ `[apparentMagnitudeThreshold]`.

`galacticFilterFormationTime` A filter which removes recently-formed halos. Halos with a formation time greater than the current time minus $\Delta t =$ `[timeRecent]` are removed.

`galacticFilterHostMassRange` Passes nodes with host halo basic mass, $M_{\rm host}$, in the range `[massMinimum]` $\leq M_{\rm host} <$ `[massMaximum]`.

`galacticFilterStellarAbsoluteMagnitudes` A galactic low-pass (i.e. bright-pass) filter for stellar absolute magnitudes. Galaxies with absolute magnitude in each band, i, less than or equal to a fixed threshold, $M_{0,i} =$ `[absoluteMagnitudeThreshold]`.

`galacticFilterHaloNotIsolated` A filter which passes only non-isolated halos.

Solvers for galactic structure

Additional implementations for solvers for galactic structure are added using the `galacticStructureSolver` class. The implementation should be placed in a file containing the directive:

```
!# <galacticStructureSolver name="galacticStructureSolverMyImplementation">
!# <description>A short description of the implementation.</description>
!# </galacticStructureSolver>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `galacticStructureSolverMyImplementation`. The file *must* define a type that extends the `galacticStructureSolverClass` class (or extends another type which is itself an extension of the `galacticStructureSolverClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (galacticStructureSolverClass), intent(inout)           :: self
  logical                              , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (galacticStructureSolverClass), intent(inout)           :: self
 type   (inputParameters             ), intent(inout)           :: descriptor
 logical                              , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`solve` Solves for the structure of components in the given `node`. Must have the following interface:

```
subroutine myImplementationSolve(self,node)
 class(galacticStructureSolverClass), intent(inout)         :: self
 type (treeNode                    ), intent(inout), target :: node
end subroutine myImplementationSolve
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(galacticStructureSolverClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (galacticStructureSolverClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                   ), intent(in   ) :: fgslStateFile
 integer(c_size_t                    ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (galacticStructureSolverClass)                          , intent(inout) :: &
&  self
 type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(galacticStructureSolverClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(galacticStructureSolverClass), intent(inout) :: self
 class(galacticStructureSolverClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`revert` Revert the structure of components in the given `node` (if necessary to ensure that the structure solver will give the same result when called consecutively). Must have the following interface:

```
subroutine myImplementationRevert(self,node)
 class(galacticStructureSolverClass), intent(inout) :: self
 type (treeNode                    ), intent(inout) :: node
end subroutine myImplementationRevert
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (galacticStructureSolverClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`galacticStructureSolverLinear` A "linear" solver for galactic structure (no self-gravity of baryons, and size simply scales in proportion to specific angular momentum).

`galacticStructureSolverEquilibrium` An "equilibrium" solver for galactic structure.

`galacticStructureSolverFixed` A "fixed" solver for galactic structure (no self-gravity of baryons, and size simply scales in proportion to specific angular momentum).

`galacticStructureSolverSimple` A simple solver for galactic structure (self-gravity of baryons is ignored).

Gaunt Factors

Additional implementations for gaunt factors are added using the `gauntFactor` class. The implementation should be placed in a file containing the directive:

```
!# <gauntFactor name="gauntFactorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </gauntFactor>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `gauntFactorMyImplementation`. The file *must* define a type that extends the `gauntFactorClass` class (or extends another type which is itself an extension of the `gauntFactorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (gauntFactorClass), intent(inout)          :: self
 logical                  , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (gauntFactorClass), intent(inout)          :: self
 type   (inputParameters ), intent(inout)          :: descriptor
 logical                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(gauntFactorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (gauntFactorClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (gauntFactorClass)                          , intent(inout) :: self
 type     (varying_string  ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*           )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`total` Returns the thermally averaged, total Gaunt factor. Must have the following interface:

```
 double precision function myImplementationTotal(self,atomicNumber, electronNumber,&
&  temperature)
  class           (gauntFactorClass), intent(inout) :: self
  integer                           , intent(in   ) :: atomicNumber, electronNumber
  double precision                  , intent(in   ) :: temperature
 end double precision function myImplementationTotal
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(gauntFactorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(gauntFactorClass), intent(inout) :: self
 class(gauntFactorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (gauntFactorClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`gauntFactorSutherland1998` Gaunt factors are computed using the fitting function of Sutherland [1998].

`gauntFactorVanHoof2014` Gaunt factors are computed using the fitting function of van Hoof et al. [2014].

Lightcone Geometries

Additional implementations for lightcone geometries are added using the `geometryLightcone` class. The implementation should be placed in a file containing the directive:

```
!# <geometryLightcone name="geometryLightconeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </geometryLightcone>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `geometryLightcone-MyImplementation`. The file *must* define a type that extends the `geometryLightconeClass` class (or extends another type which is itself an extension of the `geometryLightconeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (geometryLightconeClass), intent(inout)           :: self
 logical                        , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (geometryLightconeClass), intent(inout)           :: self
 type   (inputParameters       ), intent(inout)           :: descriptor
 logical                        , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(geometryLightconeClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (geometryLightconeClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`isInLightcone` Returns true if the provided node lies within the lightcone. Must have the following interface:

```
logical function myImplementationIsInLightcone(self,node,atPresentEpoch,radiusBuffer)
 class           (geometryLightconeClass), intent(inout)           :: self
 type            (treeNode              ), intent(inout)           :: node
 logical                                 , intent(in   ), optional :: atPresentEpoch
 double precision                        , intent(in   ), optional :: radiusBuffer
end logical function myImplementationIsInLightcone
```

`position` Returns the position vector of a `node` (in units of Mpc) in the lightcone coordinate system. Must have the following interface:

```
double precision, dimension(3) function myImplementationPosition(self,node,instance)
 class  (geometryLightconeClass), intent(inout) :: self
 type   (treeNode               ), intent(inout) :: node
 integer(c_size_t               ), intent(in   ) :: instance
end double precision, dimension(3) function myImplementationPosition
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (geometryLightconeClass)                          , intent(inout) :: self
 type     (varying_string        ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`solidAngle` Returns the solid angle subtended by the lightcone (in units of steradians). Must have the following interface:

```
double precision function myImplementationSolidAngle(self)
 class(geometryLightconeClass), intent(inout) :: self
end double precision function myImplementationSolidAngle
```

`velocity` Returns the velocity vector of a `node` (in units of km/s) in the lightcone coordinate system. Must have the following interface:

```
double precision, dimension(3) function myImplementationVelocity(self,node,instance)
 class  (geometryLightconeClass), intent(inout) :: self
 type   (treeNode              ), intent(inout) :: node
 integer(c_size_t              ), intent(in   ) :: instance
end double precision, dimension(3) function myImplementationVelocity
```

`replicationCount` Returns the number of times the given nodes appears in the lightone . Must have the following interface:

```
integer(c_size_t) function myImplementationReplicationCount(self,node)
 class(geometryLightconeClass), intent(inout) :: self
 type (treeNode              ), intent(inout) :: node
end integer(c_size_t) function myImplementationReplicationCount
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(geometryLightconeClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(geometryLightconeClass), intent(inout) :: self
 class(geometryLightconeClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (geometryLightconeClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`geometryLightconeSquare` A lightcone geometry class which assumes a square field of view., i.e. defined such that a point (x, y, z) is in the survey angular mask if $|\mathrm{atan2}(y, x)| < \psi/2$ and $|\mathrm{atan2}(z, x)| < \psi/2$ where atan2() is the quadrant-aware inverse tangent function, and ψ is the angular size of the field, we compute the solid angle of the lightcone as follows. Define a spherical coodinate system (θ, ϕ) with the pole ($\theta = 0$) aligned with the x-axis. The solid angle of the field is then

$$\Omega = 2\pi \int_0^{\psi/2} \sin\theta \mathrm{d}\theta + 8 \int_{\psi/2}^{\tan^{-1}(\sqrt{2}\tan(\psi/2))} \mathrm{d}\theta \sin\theta \int_{\cos^{-1}(\tan(\psi/2)/\tan\theta)}^{\pi/4} \mathrm{d}\phi, \tag{16.4}$$

which is

$$\Omega = 2\pi[1 - \cos(\psi/2)] + 8 \int_{\psi/2}^{\tan^{-1}(\sqrt{2}\tan(\psi/2))} \mathrm{d}\theta \sin\theta \left[\frac{\pi}{4} - \cos^{-1}\left(\frac{\tan(\psi/2)}{\tan\theta}\right)\right], \tag{16.5}$$

or

$$\Omega = 2\pi[1 - \cos(\tan^{-1}(\sqrt{2}\tan(\psi/2)))] - 8 \int_{\psi/2}^{\tan^{-1}(\sqrt{2}\tan(\psi/2))} \mathrm{d}\theta \sin\theta \cos^{-1}\left(\frac{\tan(\psi/2)}{\tan\theta}\right), \tag{16.6}$$

The final integral can be evaluated (using Mathematica for example) to give

$$\begin{aligned}\Omega \;=\; & 2\pi[3 - \cos(\tan^{-1}(\sqrt{2}\tan(\psi/2)))] - 8\sin(x)\Big(\sqrt{(a^2+1)\cos(2x)+a^2-1}(\log(a(\sqrt{2}\sqrt{2a^2\cos^2(x)+\cos(2x)-1} \\ & +2a)) - \log(\sqrt{\cos(2x)-1}))\sqrt{\csc^2(x)(-((a^2+1)\cos(2x)+a^2-1))} - \cot(x)((a^2+1)\cos(2x)+a^2-1) \\ & \cos^{-1}(a\cot(x))\Big)/[(a^2+1)\cos(2x)+a^2-1],\end{aligned} \tag{16.7}$$

where $a = \tan(\psi/2)$ and $x = \tan^{-1}[\sqrt{2}\tan(\psi/2)]$. Various sub-parameters specify the details of the light geometry. The `lengthReplication` parameter should give the length of the simulation box (the box will be replicated to span the volume covered by the lightcone), with the `lengthUnitsInSI` parameter giving the length unit in SI units and `lengthHubbleExponent` giving the exponent of h that appears in the length unit. The `angularSize` parameter of `fieldOfView` should gives the length of the side of the square field of view in degrees. The `origin` element must contain the x, y, z coordinates of the origin of the lightcone within the simulation box, while the `unitVectorX` parameters must give unit vectors which point along the lightcone (for `X`= 1), and in the two directions perpendicular to the lightcone (for `X`= 2 and 3). The `redshift` parameters must list the redshifts of available outputs.

Gravitational Lensing

Additional implementations for gravitational lensing are added using the `gravitationalLensing` class. The implementation should be placed in a file containing the directive:

```
!# <gravitationalLensing name="gravitationalLensingMyImplementation">
!# <description>A short description of the implementation.</description>
!# </gravitationalLensing>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `gravitationalLensingMyImplementation`. The file *must* define a type that extends the `gravitationalLensingClass` class (or extends another type which is itself an extension of the `gravitationalLensingClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (gravitationalLensingClass), intent(inout)          :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (gravitationalLensingClass), intent(inout)          :: self
 type   (inputParameters          ), intent(inout)          :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(gravitationalLensingClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (gravitationalLensingClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`magnificationCDF` Returns the cumulative probability function for magnification. Must have the following interface:

```
double precision function myImplementationMagnificationCDF(self,magnification, redshift&
&  , scaleSource)
 class           (gravitationalLensingClass), intent(inout) :: self
 double precision                           , intent(in   ) :: magnification, redshift,&
&   scaleSource
end double precision function myImplementationMagnificationCDF
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (gravitationalLensingClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`magnificationPDF` Returns the differential probability function for magnification. Must have the following interface:

```
 double precision function myImplementationMagnificationPDF(self,magnification, redshift&
&  , scaleSource)
  class           (gravitationalLensingClass), intent(inout) :: self
  double precision                           , intent(in   ) :: magnification, redshift,&
&   scaleSource
 end double precision function myImplementationMagnificationPDF
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(gravitationalLensingClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(gravitationalLensingClass), intent(inout) :: self
 class(gravitationalLensingClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (gravitationalLensingClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`gravitationalLensingBaryonicModifier` Implements the gravitational lensing distribution by modifying another distribution for the effects of baryons.

`gravitationalLensingTakahashi2011` Implements the gravitational lensing distributions of Takahashi et al. [2011]. See §12.19.1.

Halo Environment

Additional implementations for halo environment are added using the `haloEnvironment` class. The implementation should be placed in a file containing the directive:

```
!# <haloEnvironment name="haloEnvironmentMyImplementation">
!# <description>A short description of the implementation.</description>
!# </haloEnvironment>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `haloEnvironmentMyImplementation`. The file *must* define a type that extends the `haloEnvironmentClass` class (or extends another type which is itself an extension of the `haloEnvironmentClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`overdensityLinear` Return the environmental linear overdensity for the given `node`. Must have the following interface:

```
double precision function myImplementationOverdensityLinear(self,node,presentDay)
 class  (haloEnvironmentClass), intent(inout)           :: self
 type   (treeNode            ), intent(inout)           :: node
 logical                      , intent(in   ), optional :: presentDay
end double precision function myImplementationOverdensityLinear
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (haloEnvironmentClass), intent(inout)           :: self
 logical                      , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (haloEnvironmentClass), intent(inout)           :: self
 type   (inputParameters     ), intent(inout)           :: descriptor
 logical                      , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`overdensityNonLinear` Return the environmental non-linear overdensity for the given `node`. Must have the following interface:

```
double precision function myImplementationOverdensityNonLinear(self,node)
 class(haloEnvironmentClass), intent(inout) :: self
 type (treeNode            ), intent(inout) :: node
end double precision function myImplementationOverdensityNonLinear
```

`overdensityLinearMinimum` Return the minimum linear overdensity for which the environmental overdensity PDF is non-zero. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationOverdensityLinearMinimum(self)
 class(haloEnvironmentClass), intent(inout) :: self
end double precision function myImplementationOverdensityLinearMinimum
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(haloEnvironmentClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`overdensityLinearMaximum` Return the maximum linear overdensity for which the environmental overdensity PDF is non-zero. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationOverdensityLinearMaximum(self)
 class(haloEnvironmentClass), intent(inout) :: self
end double precision function myImplementationOverdensityLinearMaximum
```

`pdf` Return the PDF of the environmental overdensity for the given overdensity. Must have the following interface:

```
double precision function myImplementationPdf(self,overdensity)
 class           (haloEnvironmentClass), intent(inout) :: self
 double precision                      , intent(in   ) :: overdensity
end double precision function myImplementationPdf
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloEnvironmentClass), intent(inout) :: self
 integer                      , intent(in   ) :: stateFile
 type   (fgsl_file           ), intent(in   ) :: fgslStateFile
 integer(c_size_t            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`environmentRadius` Return the radius of the region used to defined the environmental. Must have the following interface:

```
double precision function myImplementationEnvironmentRadius(self)
 class(haloEnvironmentClass), intent(inout) :: self
end double precision function myImplementationEnvironmentRadius
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (haloEnvironmentClass)                          , intent(inout) :: self
 type     (varying_string      ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
```

```
 character(len=*               )                              , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`environmentMass` Return the mean mass contained in the region used to defined the environmental. Must have the following interface:

```
double precision function myImplementationEnvironmentMass(self)
 class(haloEnvironmentClass), intent(inout) :: self
end double precision function myImplementationEnvironmentMass
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(haloEnvironmentClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(haloEnvironmentClass), intent(inout) :: self
 class(haloEnvironmentClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloEnvironmentClass), intent(inout) :: self
 integer                      , intent(in   ) :: stateFile
 type   (fgsl_file           ), intent(in   ) :: fgslStateFile
 integer(c_size_t            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`overdensityLinearSet` Set the environmental overdensity for the give node. Must have the following interface:

```
subroutine myImplementationOverdensityLinearSet(self,node,overdensity)
 class           (haloEnvironmentClass), intent(inout) :: self
 type            (treeNode            ), intent(inout) :: node
 double precision                      , intent(in   ) :: overdensity
end subroutine myImplementationOverdensityLinearSet
```

`cdf` Return the CDF of the environmental overdensity for the given overdensity. Must have the following interface:

```
double precision function myImplementationCdf(self,overdensity)
 class           (haloEnvironmentClass), intent(inout) :: self
 double precision                      , intent(in   ) :: overdensity
end double precision function myImplementationCdf
```

Existing implementations are:

`haloEnvironmentUniform` Implements a uniform halo environment.

`haloEnvironmentNormal` Implements a normally-distributed halo environment.

`haloEnvironmentLogNormal` Implements a log-normal halo environment.

Halo Mass Function

Additional implementations for halo mass function are added using the `haloMassFunction` class. The implementation should be placed in a file containing the directive:

```
!# <haloMassFunction name="haloMassFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </haloMassFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `haloMassFunctionMyImplementation`. The file *must* define a type that extends the `haloMassFunctionClass` class (or extends another type which is itself an extension of the `haloMassFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`massFraction` Return the halo mass fraction at `time` [Gyr] integrated between `massLow` and `massHigh` [$M_\odot$]. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationMassFraction(self,time, massLow, massHigh,&
&  node)
  class           (haloMassFunctionClass), intent(inout)                  :: self
  double precision                       , intent(in   )                  :: time, &
&  massLow, massHigh
  type            (treeNode             ), intent(inout), optional, target :: node
 end double precision function myImplementationMassFraction
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (haloMassFunctionClass), intent(inout)           :: self
  logical                       , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (haloMassFunctionClass), intent(inout)           :: self
  type   (inputParameters      ), intent(inout)           :: descriptor
  logical                       , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(haloMassFunctionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloMassFunctionClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`integrated` Return the halo mass function at `time` [Gyr] integrated between `massLow` and `massHigh` [$M_\odot$]. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationIntegrated(self,time, massLow, massHigh,node)
 class           (haloMassFunctionClass), intent(inout)                  :: self
 double precision                       , intent(in   )                  :: time, &
&  massLow, massHigh
 type            (treeNode             ), intent(inout), optional, target :: node
end double precision function myImplementationIntegrated
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (haloMassFunctionClass)                          , intent(inout) :: self
 type     (varying_string       ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(haloMassFunctionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(haloMassFunctionClass), intent(inout) :: self
 class(haloMassFunctionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloMassFunctionClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`differential` Return the differential halo mass function for `mass` [$M_\odot$] at `time` [Gyr]. Must have the following interface:

```
double precision function myImplementationDifferential(self,time, mass,node)
 class           (haloMassFunctionClass), intent(inout)           :: self
 double precision                       , intent(in   )           :: time, mass
 type            (treeNode             ), intent(inout), optional :: node
end double precision function myImplementationDifferential
```

Existing implementations are:

`haloMassFunctionRodriguezPuebla2016` The halo mass function is computed from the function given by Tinker et al. [2008], and using the fits of Rodríguez-Puebla et al. [2016] for the parameter values.

`haloMassFunctionEnvironmental` The halo mass function is computed by handling the transition though the environment mass scale.

`haloMassFunctionErrorConvolved` The halo mass function is computed by convolving another halo mass function with a mass dependent error. Specifically, the mass function is convolved with a Gaussian random error distribution with width computed using the given `nbodyHaloMassError` object.

`haloMassFunctionFofBias` The halo mass function is computed by modifying another halo mass function to mimic systematic errors arising in the friends-of-friends halo finding algorithm. Specifically, a systematic shift in mass motivated by the results of percolation theory [More et al., 2011, their eqn. B11] is applied. In particular, $M_{\rm particle} =$`[massParticle]` is the mass of the particle in the simulation to which the friends-of-friends algorithm was applied.

`haloMassFunctionBhattacharya2011` The halo mass function is computed from the function given by Bhattacharya et al. [2011].

`haloMassFunctionTinker2008` The halo mass function is computed from the function given by Tinker et al. [2008], and using their fits for the parameter values. See §12.6.11.

`haloMassFunctionDespali2015` The halo mass function is computed from the function given by Despali et al. [2015]. See §12.6.11.

`haloMassFunctionPressSchechter` The halo mass function is computed from the function given by Press and Schechter [1974]. See §12.6.11.

`haloMassFunctionShethTormen` The halo mass function is computed from the function given by Sheth et al. [2001]. See §12.6.11.

`haloMassFunctionSimpleSystematic` The halo mass function is computed by modifying another halo mass function using a simple model for systematic errors. See §12.6.11.

`haloMassFunctionEnvironmentAveraged` The halo mass function is computed averaging another (presumably environment-dependent) mass function over environment.

`haloMassFunctionTinker2008Form` The halo mass function is computed from the function given by Tinker et al. [2008].

`haloMassFunctionTinker2008Generic` The halo mass function is computed from the function given by Tinker et al. [2008] with user-specified parameters.

Halo Model Power Spectrum Modifier

Additional implementations for halo model power spectrum modifier are added using the `haloModelPowerSpectrumModifier` class. The implementation should be placed in a file containing the directive:

```
!# <haloModelPowerSpectrumModifier name="haloModelPowerSpectrumModifierMyImplementation">
!# <description>A short description of the implementation.</description>
!# </haloModelPowerSpectrumModifier>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `haloModelPowerSpectrumModifierMyImplementation`. The file *must* define a type that extends the `haloModelPowerSpectrumModifierClass` class (or extends another type which is itself an extension of the `haloModelPowerSpectrumModifierClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (haloModelPowerSpectrumModifierClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (haloModelPowerSpectrumModifierClass), intent(inout)           :: self
 type   (inputParameters                    ), intent(inout)           :: descriptor
 logical                                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(haloModelPowerSpectrumModifierClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloModelPowerSpectrumModifierClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (haloModelPowerSpectrumModifierClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(haloModelPowerSpectrumModifierClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(haloModelPowerSpectrumModifierClass), intent(inout) :: self
 class(haloModelPowerSpectrumModifierClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`modify` Modify the power spectra in the halo model of clustering. Must have the following interface:

```
subroutine myImplementationModify(self,wavenumber,term,powerSpectrum,&
&  powerSpectrumCovariance,mass)
 class           (haloModelPowerSpectrumModifierClass)               , intent(inout)  &
&           :: self
 double precision                                     , dimension(:)  , intent(in   )  &
&           :: wavenumber
 integer                                                             , intent(in   )  &
&           :: term
 double precision                                     , dimension(:)  , intent(inout)  &
&           :: powerSpectrum
 double precision                                     , dimension(:,:), intent(inout), &
&  optional :: powerSpectrumCovariance
 double precision                                                    , intent(in   ), &
&  optional :: mass
 end subroutine myImplementationModify
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloModelPowerSpectrumModifierClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`haloModelPowerSpectrumModifierIdentity` A identity modifier for power spectra in the halo model of clustering.

`haloModelPowerSpectrumModifierTriaxiality` A triaxiality modifier for power spectra in the halo model of clustering based on the results of Smith and Watts [2005]. See §12.20.2.

Dark Matter Halo Spin Parameter Distributions

Additional implementations for dark matter halo spin parameter distributions are added using the `haloSpinDistribution` class. The implementation should be placed in a file containing the directive:

```
!# <haloSpinDistribution name="haloSpinDistributionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </haloSpinDistribution>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `haloSpinDistribution-MyImplementation`. The file *must* define a type that extends the `haloSpinDistributionClass` class (or extends another type which is itself an extension of the `haloSpinDistributionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (haloSpinDistributionClass), intent(inout)          :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (haloSpinDistributionClass), intent(inout)          :: self
 type   (inputParameters          ), intent(inout)          :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(haloSpinDistributionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloSpinDistributionClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (haloSpinDistributionClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`distribution` Return the spin distribution function, $p(\lambda)$, for the given `node`. It is assumed that `node` provides the value of the spin at which the distribution function should be evaluated. Must have the following interface:

```
double precision function myImplementationDistribution(self,node)
 class(haloSpinDistributionClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationDistribution
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(haloSpinDistributionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(haloSpinDistributionClass), intent(inout) :: self
 class(haloSpinDistributionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`sample` Samples a spin parameter from the distribution for the given `node`. Must have the following interface:

```
double precision function myImplementationSample(self,node)
 class(haloSpinDistributionClass), intent(inout) :: self
 type (treeNode                 ), intent(inout) :: node
end double precision function myImplementationSample
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (haloSpinDistributionClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`haloSpinDistributionBett2007` A halo spin distribution using the fitting formula of Bett et al. [2007]. See §12.11.7.

`haloSpinDistributionNbodyErrors` A halo spin distribution which modifies another spin distribution to account for the effects of particle noise errors in spins measured in N-body simulations.

`haloSpinDistributionLogNormal` A log-normal halo spin distribution. See §12.11.7.

`haloSpinDistributionDeltaFunction` A δ-function halo spin distribution. See §12.11.7.

Cold Mode Hot Halo Mass Distributions Core Radii

Additional implementations for cold mode hot halo mass distributions core radii are added using the `hotHaloColdModeCoreRadii` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloColdModeCoreRadii name="hotHaloColdModeCoreRadiiMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloColdModeCoreRadii>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloColdModeCoreRadiiMyImplementation`. The file *must* define a type that extends the `hotHaloColdModeCoreRadiiClass` class (or extends another type which is itself an extension of the `hotHaloColdModeCoreRadiiClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (hotHaloColdModeCoreRadiiClass), intent(inout)           :: self
 logical                               , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (hotHaloColdModeCoreRadiiClass), intent(inout)           :: self
 type   (inputParameters              ), intent(inout)           :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(hotHaloColdModeCoreRadiiClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`radius` Return the core radius of the hot halo mass distribution. Must have the following interface:

```
double precision function myImplementationRadius(self,node)
 class(hotHaloColdModeCoreRadiiClass), intent(inout) :: self
 type (treeNode                     ), intent(inout) :: node
end double precision function myImplementationRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloColdModeCoreRadiiClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloColdModeCoreRadiiClass)                          , intent(inout) :: &
&  self
 type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloColdModeCoreRadiiClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloColdModeCoreRadiiClass), intent(inout) :: self
 class(hotHaloColdModeCoreRadiiClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloColdModeCoreRadiiClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`hotHaloColdModeCoreRadiiVirialFraction` Provides an implementation of the cold mode hot halo mass distribution core radius class which sets the core radius to a fraction of the virial radius.

Hot Halo Mass Distributions

Additional implementations for hot halo mass distributions are added using the `hotHaloMassDistribution` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloMassDistribution name="hotHaloMassDistributionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloMassDistribution>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloMassDistributionMyImplementation`. The file *must* define a type that extends the `hotHaloMassDistributionClass` class (or extends another type which is itself an extension of the `hotHaloMassDistributionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (hotHaloMassDistributionClass), intent(inout)           :: self
 logical                              , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (hotHaloMassDistributionClass), intent(inout)           :: self
 type   (inputParameters             ), intent(inout)           :: descriptor
 logical                              , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(hotHaloMassDistributionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`enclosedMass` Return the mass enclosed in the hot halo at the given `radius`. Must have the following interface:

```
double precision function myImplementationEnclosedMass(self,node,radius)
 class           (hotHaloMassDistributionClass), intent(inout)         :: self
 type            (treeNode                   ), intent(inout), target :: node
 double precision                             , intent(in   )         :: radius
end double precision function myImplementationEnclosedMass
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloMassDistributionClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloMassDistributionClass)                          , intent(inout) :: &
&  self
 type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                       )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`density` Return the density of the hot halo at the given `radius`. Must have the following interface:

```
double precision function myImplementationDensity(self,node,radius)
 class           (hotHaloMassDistributionClass), intent(inout) :: self
 type            (treeNode                   ), intent(inout) :: node
 double precision                             , intent(in   ) :: radius
end double precision function myImplementationDensity
```

`rotationNormalization` Returns the relation between specific angular momentum and rotation velocity (assuming a rotation velocity that is constant in radius) for `node`. Specifically, the normalization, A, returned is such that $V_{\rm rot} = AJ/M$. Must have the following interface:

```
double precision function myImplementationRotationNormalization(self,node)
 class(hotHaloMassDistributionClass), intent(inout) :: self
 type (treeNode                   ), intent(inout) :: node
end double precision function myImplementationRotationNormalization
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloMassDistributionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloMassDistributionClass), intent(inout) :: self
 class(hotHaloMassDistributionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloMassDistributionClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`densityLogSlope` Return the logarithmic slope of the density of the hot halo at the given `radius`. Must have the following interface:

```
double precision function myImplementationDensityLogSlope(self,node,radius)
 class           (hotHaloMassDistributionClass), intent(inout) :: self
 type            (treeNode                    ), intent(inout) :: node
 double precision                              , intent(in   ) :: radius
end double precision function myImplementationDensityLogSlope
```

`radialMoment` Return the density of the hot halo at the given `radius`. Must have the following interface:

```
double precision function myImplementationRadialMoment(self,node,moment, radius)
 class           (hotHaloMassDistributionClass), intent(inout) :: self
 type            (treeNode                    ), intent(inout) :: node
 double precision                              , intent(in   ) :: moment, radius
end double precision function myImplementationRadialMoment
```

Existing implementations are:

`hotHaloMassDistributionBetaProfile` Provides a β-profile implementation of the hot halo mass distribution class. See §12.21.1.

`hotHaloMassDistributionRicotti2000` Provides an implementation of the hot halo mass distribution class which uses the model of Ricotti and Shull [2000]. See §12.21.2.

`hotHaloMassDistributionEnzoHydrostatic` Provides an implementation of the hot halo mass distribution class which uses the "hydrostatic" profile used by the Enzo simulation code. See §12.21.4.

`hotHaloMassDistributionNull` Provides a null implementation of the hot halo mass distribution class. See §12.21.3.

`hotHaloMassDistributionPatejLoeb2015` Provides an implementation of the hot halo mass distribution class which uses the model of Patej and Loeb [2015].

Hot Halo Mass Distributions Core Radii

Additional implementations for hot halo mass distributions core radii are added using the `hotHaloMassDistributionCoreRadi` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloMassDistributionCoreRadius name="hotHaloMassDistributionCoreRadiusMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloMassDistributionCoreRadius>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloMassDistributionCoreRadiusMyImplementation`. The file *must* define a type that extends the `hotHaloMassDistributionCoreRadiusClass` class (or extends another type which is itself an extension of the `hotHaloMassDistributionCoreRadiusClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (hotHaloMassDistributionCoreRadiusClass), intent(inout)           :: self
  logical                                        , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (hotHaloMassDistributionCoreRadiusClass), intent(inout)           :: self
  type   (inputParameters                       ), intent(inout)           :: descriptor
  logical                                        , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(hotHaloMassDistributionCoreRadiusClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`radius` Return the core radius of the hot halo mass distribution. Must have the following interface:

```
 double precision function myImplementationRadius(self,node)
  class(hotHaloMassDistributionCoreRadiusClass), intent(inout) :: self
  type (treeNode                               ), intent(inout) :: node
 end double precision function myImplementationRadius
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloMassDistributionCoreRadiusClass), intent(inout) :: self
 integer                                        , intent(in   ) :: stateFile
 type   (fgsl_file                              ), intent(in   ) :: fgslStateFile
 integer(c_size_t                               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloMassDistributionCoreRadiusClass)                          , intent(&
&  inout) :: self
 type     (varying_string                        ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                                 )                          , intent(&
&  in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloMassDistributionCoreRadiusClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloMassDistributionCoreRadiusClass), intent(inout) :: self
 class(hotHaloMassDistributionCoreRadiusClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloMassDistributionCoreRadiusClass), intent(inout) :: self
 integer                                        , intent(in   ) :: stateFile
 type   (fgsl_file                              ), intent(in   ) :: fgslStateFile
 integer(c_size_t                               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`hotHaloMassDistributionCoreRadiusVirialFraction` Provides an implementation of the hot halo mass distribution core radius class which sets the core radius to a fraction of the virial radius. See §12.22.2.

`hotHaloMassDistributionCoreRadiusGrowing` Provides an implementation of the hot halo mass distribution core radius class in which the core grows as the hot halo content is depleted. See §12.22.1.

Hot Halo Outflow Reincorporation

Additional implementations for hot halo outflow reincorporation are added using the `hotHaloOutflowReincorporation` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloOutflowReincorporation name="hotHaloOutflowReincorporationMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloOutflowReincorporation>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloOutflowReincorporationMyImplementation`. The file *must* define a type that extends the `hotHaloOutflowReincorporationClass` class (or extends another type which is itself an extension of the `hotHaloOutflowReincorporationClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (hotHaloOutflowReincorporationClass), intent(inout)          :: self
  logical                                    , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (hotHaloOutflowReincorporationClass), intent(inout)          :: self
 type   (inputParameters                   ), intent(inout)          :: descriptor
 logical                                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(hotHaloOutflowReincorporationClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloOutflowReincorporationClass), intent(inout) :: self
 integer                                    , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloOutflowReincorporationClass)                          , intent(inout&
&  ) :: self
 type     (varying_string                    ), allocatable, dimension(:), intent(inout&
&  ) :: allowedParameters
 character(len=*                             )                          , intent(in   &
&  ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`rate` Return the rate at which outflowed mass is being reincorporated into the hot halo. Must have the following interface:

```
double precision function myImplementationRate(self,node)
 class(hotHaloOutflowReincorporationClass), intent(inout) :: self
 type (treeNode                          ), intent(inout) :: node
end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloOutflowReincorporationClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloOutflowReincorporationClass), intent(inout) :: self
 class(hotHaloOutflowReincorporationClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloOutflowReincorporationClass), intent(inout) :: self
 integer                                    , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`hotHaloOutflowReincorporationHaloDynamicalTime` An implementation of the hot halo outflow reincorporation class in which reincorporation occurs on a multiple of the halo dynamical timescale.

`hotHaloOutflowReincorporationZero` An implementation of the hot halo outflow reincorporation class which gives zero reincorporation rate.

`hotHaloOutflowReincorporationVelocityMaximumScaling` An implementation of the hot halo outflow reincorporation class which uses simple scalings based on the halo maximum circular velocity. See §12.26.1.

`hotHaloOutflowReincorporationHenriques2013` An implementation of the hot halo outflow reincorporation class which implements the model of Henriques et al. [2013]. Specifically, outflowed gas is returned at a rate:

$$\dot{M}_{\rm return} = \gamma(1+z)^{-\delta_1}\left(\frac{V_{\rm vir}}{200{\rm km/s}}\right)^{\delta_2}\frac{M_{\rm outflowed}}{\tau_{\rm dyn}} \tag{16.8}$$

Models of ram pressure force from the hot halo.

Additional implementations for models of ram pressure force from the hot halo. are added using the `hotHaloRamPressureForce` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloRamPressureForce name="hotHaloRamPressureForceMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloRamPressureForce>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloRamPressureForceMyImplementation`. The file *must* define a type that extends the `hotHaloRamPressureForceClass` class (or extends another type which is itself an extension of the `hotHaloRamPressureForceClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (hotHaloRamPressureForceClass), intent(inout)           :: self
  logical                              , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (hotHaloRamPressureForceClass), intent(inout)           :: self
  type   (inputParameters             ), intent(inout)           :: descriptor
  logical                              , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(hotHaloRamPressureForceClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloRamPressureForceClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloRamPressureForceClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`force` Return the ram pressure force acting on `node` (in units of $(\mathrm{km/s})^2 M_\odot/\mathrm{Mpc}^3$). Must have the following interface:

```
double precision function myImplementationForce(self,node)
 class(hotHaloRamPressureForceClass), intent(inout) :: self
 type (treeNode                    ), intent(inout) :: node
end double precision function myImplementationForce
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloRamPressureForceClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloRamPressureForceClass), intent(inout) :: self
 class(hotHaloRamPressureForceClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloRamPressureForceClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`hotHaloRamPressureForceZero` A hot halo ram pressure force class which follows the model of Font et al. [2008].

`hotHaloRamPressureForceFont2008` A hot halo ram pressure force class which follows the model of Font et al. [2008].

Models of ram pressure stripping due to the hot halo.

Additional implementations for models of ram pressure stripping due to the hot halo. are added using the `hotHaloRamPressureStripping` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloRamPressureStripping name="hotHaloRamPressureStrippingMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloRamPressureStripping>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloRamPressureStrippingMyImplementation`. The file *must* define a type that extends the `hotHaloRamPressureStrippingClass` class (or extends another type which is itself an extension of the `hotHaloRamPressureStrippingClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (hotHaloRamPressureStrippingClass), intent(inout)          :: self
  logical                                  , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (hotHaloRamPressureStrippingClass), intent(inout)          :: self
 type   (inputParameters                 ), intent(inout)          :: descriptor
 logical                                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(hotHaloRamPressureStrippingClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloRamPressureStrippingClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloRamPressureStrippingClass)                          , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`radiusStripped` Return the radius to which `node` is stripped due to ram pressure from its host halo (in units of Mpc). Must have the following interface:

```
double precision function myImplementationRadiusStripped(self,node)
 class(hotHaloRamPressureStrippingClass), intent(inout)         :: self
 type (treeNode                        ), intent(inout), target :: node
end double precision function myImplementationRadiusStripped
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloRamPressureStrippingClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloRamPressureStrippingClass), intent(inout) :: self
 class(hotHaloRamPressureStrippingClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloRamPressureStrippingClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`hotHaloRamPressureStrippingVirialRadius` A hot halo ram pressure stripping class which simply returns the virial radius.

`hotHaloRamPressureStrippingFont2008` A hot halo ram pressure stripping class based on the methods of Font et al. [2008].

Models of ram pressure stripping timescales due to the hot halo.

Additional implementations for models of ram pressure stripping timescales due to the hot halo. are added using the `hotHaloRamPressureTimescale` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloRamPressureTimescale name="hotHaloRamPressureTimescaleMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloRamPressureTimescale>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloRamPressure-TimescaleMyImplementation`. The file *must* define a type that extends the `hotHaloRamPressureTimescaleClass` class (or extends another type which is itself an extension of the `hotHaloRamPressureTimescaleClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (hotHaloRamPressureTimescaleClass), intent(inout)           :: self
  logical                                  , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (hotHaloRamPressureTimescaleClass), intent(inout)           :: self
 type   (inputParameters                 ), intent(inout)           :: descriptor
 logical                                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(hotHaloRamPressureTimescaleClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloRamPressureTimescaleClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloRamPressureTimescaleClass)                          , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`timescale` Return the ram pressure stripping timescale for `node` (in units of Gyr). Must have the following interface:

```
double precision function myImplementationTimescale(self,node)
 class(hotHaloRamPressureTimescaleClass), intent(inout) :: self
 type (treeNode                        ), intent(inout) :: node
end double precision function myImplementationTimescale
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloRamPressureTimescaleClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloRamPressureTimescaleClass), intent(inout) :: self
 class(hotHaloRamPressureTimescaleClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloRamPressureTimescaleClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`hotHaloRamPressureTimescaleHaloDynamicalTime` A hot halo ram pressure timescale class in which the timescale is equal to the halo dynamical time.

`hotHaloRamPressureTimescaleRamPressureAcceleration` A hot halo ram pressure timescale class in which the timescale is estimated from the ram pressure acceleration.

Hot halo temperature profiles

Additional implementations for hot halo temperature profiles are added using the `hotHaloTemperatureProfile` class. The implementation should be placed in a file containing the directive:

```
!# <hotHaloTemperatureProfile name="hotHaloTemperatureProfileMyImplementation">
!# <description>A short description of the implementation.</description>
!# </hotHaloTemperatureProfile>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `hotHaloTemperatureProfileMyImplementation`. The file *must* define a type that extends the `hotHaloTemperatureProfileClass` class (or extends another type which is itself an extension of the `hotHaloTemperatureProfileClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`temperatureLogSlope` Return the logarithmic slope of the temperature of the hot halo at the given `radius`. Must have the following interface:

```
double precision function myImplementationTemperatureLogSlope(self,node,radius)
 class           (hotHaloTemperatureProfileClass), intent(inout) :: self
 type            (treeNode                      ), intent(inout) :: node
 double precision                                , intent(in   ) :: radius
end double precision function myImplementationTemperatureLogSlope
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (hotHaloTemperatureProfileClass), intent(inout)           :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (hotHaloTemperatureProfileClass), intent(inout)           :: self
 type   (inputParameters               ), intent(inout)           :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(hotHaloTemperatureProfileClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloTemperatureProfileClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (hotHaloTemperatureProfileClass)                          , intent(inout) ::&
&  self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) ::&
&  allowedParameters
 character(len=*                         )                          , intent(in   ) ::&
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(hotHaloTemperatureProfileClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(hotHaloTemperatureProfileClass), intent(inout) :: self
 class(hotHaloTemperatureProfileClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (hotHaloTemperatureProfileClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`temperature` Return the temperature of the hot halo at the given `radius`. Must have the following interface:

```
double precision function myImplementationTemperature(self,node,radius)
 class           (hotHaloTemperatureProfileClass), intent(inout) :: self
 type            (treeNode                      ), intent(inout) :: node
 double precision                                , intent(in   ) :: radius
end double precision function myImplementationTemperature
```

Existing implementations are:

`hotHaloTemperatureProfileVirial` Provides an implementation of the hot halo temperature profile class which uses an isothermal virial temperature. See §12.27.1.

`hotHaloTemperatureProfileEnzoHydrostatic` Provides an implementation of the hot halo temperature profile class which uses the "hydrostatic" solution from the Enzo code. See §12.27.2.

Initial Mass Functions

Additional implementations for initial mass functions are added using the `initialMassFunction` class. The implementation should be placed in a file containing the directive:

```
!# <initialMassFunction name="initialMassFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </initialMassFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `initialMassFunction-MyImplementation`. The file *must* define a type that extends the `initialMassFunctionClass` class (or extends another type which is itself an extension of the `initialMassFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (initialMassFunctionClass), intent(inout)          :: self
  logical                          , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (initialMassFunctionClass), intent(inout)          :: self
  type   (inputParameters         ), intent(inout)          :: descriptor
  logical                          , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(initialMassFunctionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (initialMassFunctionClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`tabulate` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`initialMass`. Must have the following interface:

```
subroutine myImplementationTabulate(self,imfTable)
 class(initialMassFunctionClass)             , intent(inout) :: self
 class(table1D                 ), allocatable, intent(inout) :: imfTable
end subroutine myImplementationTabulate
```

`massMinimum` Return the minimum mass in the initial mass function. Must have the following interface:

```
double precision function myImplementationMassMinimum(self)
 class(initialMassFunctionClass), intent(inout) :: self
end double precision function myImplementationMassMinimum
```

`massMaximum` Return the maximum mass in the initial mass function. Must have the following interface:

```
double precision function myImplementationMassMaximum(self)
 class(initialMassFunctionClass), intent(inout) :: self
end double precision function myImplementationMassMaximum
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (initialMassFunctionClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(initialMassFunctionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`phi` Return the initial mass function, $\phi(M) = \mathrm{d}N/\mathrm{d}M$, at the given mass $M =$`massInitial`. Must have the following interface:

```
double precision function myImplementationPhi(self,massInitial)
 class           (initialMassFunctionClass), intent(inout) :: self
 double precision                          , intent(in   ) :: massInitial
end double precision function myImplementationPhi
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(initialMassFunctionClass), intent(inout) :: self
 class(initialMassFunctionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`label` Return the label for this IMF. Must have the following interface:

```
type(varying_string) function myImplementationLabel(self)
 class(initialMassFunctionClass), intent(inout) :: self
end type(varying_string) function myImplementationLabel
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (initialMassFunctionClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`initialMassFunctionPiecewisePowerLaw` A stellar initial mass function class for piecewise power-law IMFs.

`initialMassFunctionChabrier2001` A stellar initial mass function class based on Chabrier [2001].

`initialMassFunctionSalpeter1955` A stellar initial mass function class for the Salpeter [1955] IMF.

`initialMassFunctionKennicutt1983` A stellar initial mass function class for the Kennicutt [1983] IMF.

`initialMassFunctionScalo1986` A stellar initial mass function class for the Scalo [1986] IMF.

`initialMassFunctionBPASS` A stellar initial mass function class used by the BPASS library.

`initialMassFunctionBaugh2005TopHeavy` A stellar initial mass function class for the top-heavy stellar initial mass function from Baugh et al. [2005].

`initialMassFunctionMillerScalo1979` A stellar initial mass function class for the Miller and Scalo [1979] IMF.

`initialMassFunctionKroupa2001` A stellar initial mass function class for the Kroupa [2001] IMF.

Intergalactic Medium Filtering Mass

Additional implementations for intergalactic medium filtering mass are added using the `intergalacticMediumFilteringMass` class. The implementation should be placed in a file containing the directive:

```
!# <intergalacticMediumFilteringMass name="intergalacticMediumFilteringMassMyImplementation">
!# <description>A short description of the implementation.</description>
!# </intergalacticMediumFilteringMass>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `intergalacticMediumFilteringMassMyImplementation`. The file *must* define a type that extends the `intergalacticMediumFilteringMassClass` class (or extends another type which is itself an extension of the `intergalacticMediumFilteringMassClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (intergalacticMediumFilteringMassClass), intent(inout)           :: self
  logical                                       , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (intergalacticMediumFilteringMassClass), intent(inout)           :: self
  type   (inputParameters                      ), intent(inout)           :: descriptor
  logical                                       , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(intergalacticMediumFilteringMassClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (intergalacticMediumFilteringMassClass), intent(inout) :: self
  integer                                       , intent(in   ) :: stateFile
  type   (fgsl_file                             ), intent(in   ) :: fgslStateFile
  integer(c_size_t                              ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (intergalacticMediumFilteringMassClass)                          , intent(&
&  inout) :: self
 type     (varying_string                      ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                                )                          , intent(in&
&     ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`massFiltering` Return the filtering mass at the given `time`. Must have the following interface:

```
double precision function myImplementationMassFiltering(self,time)
 class           (intergalacticMediumFilteringMassClass), intent(inout) :: self
 double precision                                       , intent(in   ) :: time
end double precision function myImplementationMassFiltering
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(intergalacticMediumFilteringMassClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(intergalacticMediumFilteringMassClass), intent(inout) :: self
 class(intergalacticMediumFilteringMassClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (intergalacticMediumFilteringMassClass), intent(inout) :: self
 integer                                       , intent(in   ) :: stateFile
 type   (fgsl_file                             ), intent(in   ) :: fgslStateFile
 integer(c_size_t                              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`intergalacticMediumFilteringMassGnedin2000` An implementation of the Gnedin [2000] filtering mass calculation.

Intergalactic Medium State

Additional implementations for intergalactic medium state are added using the `intergalacticMediumState` class. The implementation should be placed in a file containing the directive:

```
!# <intergalacticMediumState name="intergalacticMediumStateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </intergalacticMediumState>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `intergalacticMediumStateMyImplementation`. The file *must* define a type that extends the `intergalacticMediumStateClass` class (or extends another type which is itself an extension of the `intergalacticMediumStateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`singlyIonizedHeliumFraction` Return the singly-ionized fraction of helium in the IGM at the given time. Must have the following interface:

```
double precision function myImplementationSinglyIonizedHeliumFraction(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationSinglyIonizedHeliumFraction
```

`massJeans` Return the instantaneus Jeans mass (in $M_\odot$) at the given time. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationMassJeans(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationMassJeans
```

`electronScatteringTime` Return the cosmological time at which the given electron scattering `opticalDepth` is reached (integrating from the present day) in the IGM. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationElectronScatteringTime(self,opticalDepth,&
&  assumeFullyIonized)
  class           (intergalacticMediumStateClass), intent(inout)           :: self
  double precision                               , intent(in   )           :: &
&  opticalDepth
  logical                                        , intent(in   ), optional :: &
&  assumeFullyIonized
 end double precision function myImplementationElectronScatteringTime
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(intergalacticMediumStateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`electronScatteringOpticalDepth` Return the electron scattering optical depth from the present day back to the given `time` in the IGM. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationElectronScatteringOpticalDepth(self,time,&
&  assumeFullyIonized)
  class           (intergalacticMediumStateClass), intent(inout)           :: self
  double precision                               , intent(in   )           :: time
  logical                                        , intent(in   ), optional :: &
&  assumeFullyIonized
 end double precision function myImplementationElectronScatteringOpticalDepth
```

`neutralHydrogenFraction` Return the neutral fraction of hydrogen in the IGM at the given time. Must have the following interface:

```
double precision function myImplementationNeutralHydrogenFraction(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationNeutralHydrogenFraction
```

`temperature` Return the temperature (in Kelvin) of the IGM at the given time. Must have the following interface:

```
double precision function myImplementationTemperature(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationTemperature
```

`doublyIonizedHeliumFraction` Return the doubly-ionized fraction of helium in the IGM at the given time. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationDoublyIonizedHeliumFraction(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationDoublyIonizedHeliumFraction
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (intergalacticMediumStateClass), intent(inout)           :: self
 type   (inputParameters              ), intent(inout)           :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (intergalacticMediumStateClass), intent(inout)           :: self
 logical                               , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`electronFraction` Return the electron fraction (relative to hydrogen) in the IGM at the given time. Must have the following interface:

```
double precision function myImplementationElectronFraction(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationElectronFraction
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(intergalacticMediumStateClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (intergalacticMediumStateClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (intergalacticMediumStateClass)                          , intent(inout) :: &
&  self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                         )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`neutralHeliumFraction` Return the neutral fraction of helium in the IGM at the given time. Must have the following interface:

```
double precision function myImplementationNeutralHeliumFraction(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationNeutralHeliumFraction
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(intergalacticMediumStateClass), intent(inout) :: self
 class(intergalacticMediumStateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (intergalacticMediumStateClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`singlyIonizedHydrogenFraction` Return the singly-ionized fraction of hydrogen in the IGM at the given time. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationSinglyIonizedHydrogenFraction(self,time)
 class           (intergalacticMediumStateClass), intent(inout) :: self
 double precision                               , intent(in   ) :: time
end double precision function myImplementationSinglyIonizedHydrogenFraction
```

Existing implementations are:

`intergalacticMediumStateInstantReionization` The intergalactic medium is assumed to be instantaneously and fully reionized at a fixed redshift, and heated to a fixed temperature. Prior to that, the reionization state is provided by some other class.

`intergalacticMediumStateSimple` The intergalactic medium is assumed to be instantaneously and fully reionized at a fixed redshift, and heated to a fixed temperature. See §12.29.1.

`intergalacticMediumStateInternal` The state of the intergalactic medium is solved for internally.

`intergalacticMediumStateFile` The intergalactic medium state is read from file. See §12.29.3.

`intergalacticMediumStateRecFast` The intergalactic medium state is computed using RecFast. See §12.29.2.

Linear Growth of Cosmological Structure

Additional implementations for linear growth of cosmological structure are added using the `linearGrowth` class. The implementation should be placed in a file containing the directive:

```
!# <linearGrowth name="linearGrowthMyImplementation">
!# <description>A short description of the implementation.</description>
!# </linearGrowth>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `linearGrowthMyImplementation`. The file *must* define a type that extends the `linearGrowthClass` class (or extends another type which is itself an extension of the `linearGrowthClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (linearGrowthClass), intent(inout)           :: self
  logical                   , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (linearGrowthClass), intent(inout)           :: self
  type   (inputParameters  ), intent(inout)           :: descriptor
  logical                   , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(linearGrowthClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`value` Return the linear growth factor at the given time and mass. Must have the following interface:

```
 double precision function myImplementationValue(self,time      , expansionFactor,&
&  collapsing,normalize , component,wavenumber)
  class           (linearGrowthClass), intent(inout)           :: self
  double precision                   , intent(in   ), optional :: time, expansionFactor
  logical                            , intent(in   ), optional :: collapsing
  integer                            , intent(in   ), optional :: normalize, component
  double precision                   , intent(in   ), optional :: wavenumber
 end double precision function myImplementationValue
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (linearGrowthClass), intent(inout) :: self
  integer                   , intent(in   ) :: stateFile
  type   (fgsl_file        ), intent(in   ) :: fgslStateFile
  integer(c_size_t         ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (linearGrowthClass)                          , intent(inout) :: self
  type     (varying_string   ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*            )                          , intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`logarithmicDerivativeExpansionFactor` Return the logarithmic derivative of linear growth factor with respect to expansion factor. Must have the following interface:

```
 double precision function myImplementationLogarithmicDerivativeExpansionFactor(self,&
&  time      , expansionFactor,collapsing,component,wavenumber)
  class           (linearGrowthClass), intent(inout)           :: self
  double precision                   , intent(in   ), optional :: time, expansionFactor
  logical                            , intent(in   ), optional :: collapsing
  integer                            , intent(in   ), optional :: component
  double precision                   , intent(in   ), optional :: wavenumber
 end double precision function myImplementationLogarithmicDerivativeExpansionFactor
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(linearGrowthClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(linearGrowthClass), intent(inout) :: self
 class(linearGrowthClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (linearGrowthClass), intent(inout) :: self
 integer                   , intent(in   ) :: stateFile
 type   (fgsl_file        ), intent(in   ) :: fgslStateFile
 integer(c_size_t         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`linearGrowthSimple` Linear growth of cosmological structure in simple cosomologies. Ignores pressure terms for the growth of baryons and has no wavenumber dependence. Also assumes no growth of radiation perturbations.

Mass Distributions

Additional implementations for mass distributions are added using the `massDistribution` class. The implementation should be placed in a file containing the directive:

```
!# <massDistribution name="massDistributionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </massDistribution>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `massDistribution-MyImplementation`. The file *must* define a type that extends the `massDistributionClass` class (or

extends another type which is itself an extension of the `massDistributionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`potential` Return the gravitational potential of the distribution at the given coordinates. Must have the following interface:

```
double precision function myImplementationPotential(self,coordinates)
 class(massDistributionClass), intent(inout) :: self
 class(coordinate           ), intent(in   ) :: coordinates
end double precision function myImplementationPotential
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(massDistributionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`massEnclosedBySphere` Return the mass enclosed in the distribution by a sphere of given radius. Must have the following interface:

```
double precision function myImplementationMassEnclosedBySphere(self,radius)
 class           (massDistributionClass), intent(inout) :: self
 double precision                       , intent(in   ) :: radius
end double precision function myImplementationMassEnclosedBySphere
```

`densityGradientRadial` Return the radial gradient of density of the distribution at the given coordinates. Must have the following interface:

```
double precision function myImplementationDensityGradientRadial(self,coordinates,&
&  logarithmic)
 class  (massDistributionClass), intent(inout)           :: self
 class  (coordinate           ), intent(in   )           :: coordinates
 logical                       , intent(in   ), optional :: logarithmic
end double precision function myImplementationDensityGradientRadial
```

`massTotal` Return the total mass of the distribution. Must have the following interface:

```
double precision function myImplementationMassTotal(self)
 class(massDistributionClass), intent(inout) :: self
end double precision function myImplementationMassTotal
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (massDistributionClass), intent(inout)           :: self
 type   (inputParameters      ), intent(inout)           :: descriptor
 logical                       , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (massDistributionClass), intent(inout)          :: self
  logical                       , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(massDistributionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (massDistributionClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (massDistributionClass)                          , intent(inout) :: self
 type     (varying_string       ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                )                           , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`density` Return the density of the distribution at the given coordinates. Must have the following interface:

```
double precision function myImplementationDensity(self,coordinates)
 class(massDistributionClass), intent(inout) :: self
 class(coordinate           ), intent(in   ) :: coordinates
end double precision function myImplementationDensity
```

`symmetry` Return the symmetry of the distribution. Must have the following interface:

```
integer function myImplementationSymmetry(self)
 class(massDistributionClass), intent(inout) :: self
end integer function myImplementationSymmetry
```

`isDimensionless` Return true if the distribution is dimensionless. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationIsDimensionless(self)
 class(massDistributionClass), intent(inout) :: self
end logical function myImplementationIsDimensionless
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(massDistributionClass), intent(inout) :: self
 class(massDistributionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (massDistributionClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`densityRadialMoment` Return the radial moment of the distribution. Must have the following interface:

```
 double precision function myImplementationDensityRadialMoment(self,moment,radiusMinimum&
&  , radiusMaximum,isInfinite)
  class           (massDistributionClass), intent(inout)           :: self
  double precision                       , intent(in   )           :: moment
  double precision                       , intent(in   ), optional :: radiusMinimum, &
&  radiusMaximum
  logical                                , intent(  out), optional :: isInfinite
 end double precision function myImplementationDensityRadialMoment
```

Existing implementations are:

`massDistributionHernquist` A Hernquist [1990] mass distribution class.

`massDistributionSersic` A Sérsic mass distribution class.

`massDistributionMiyamotoNagai` An Miyamoto-Nagai model [Miyamoto and Nagai, 1975] mass distribution class.

`massDistributionSpherical` An abstract mass distribution class for spherically symmetric distributions.

`massDistributionExponentialDisk` The exponential disk mass distribution: $\rho(r,z) = \rho_0 \exp(-r/r_\mathrm{s})\mathrm{sech}^2(z/z_\mathrm{s})$.

`massDistributionBetaProfile` An mass distribution class for β-profile distributions.

`massDistributionNFW` An NFW [Navarro et al., 1996] mass distribution class.

`massDistributionCylindrical` An abstract mass distribution class for cylindrically symmetric distributions.

Mass Function Incompletenesses

Additional implementations for mass function incompletenesses are added using the `massFunctionIncompleteness` class. The implementation should be placed in a file containing the directive:

```
!# <massFunctionIncompleteness name="massFunctionIncompletenessMyImplementation">
!# <description>A short description of the implementation.</description>
!# </massFunctionIncompleteness>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `massFunctionIncompletenessMyImplementation`. The file *must* define a type that extends the `massFunctionIncompletenessClass` class (or extends another type which is itself an extension of the `massFunctionIncompletenessClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (massFunctionIncompletenessClass), intent(inout)           :: self
  logical                                 , intent(in   ), optional :: &
& includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (massFunctionIncompletenessClass), intent(inout)           :: self
 type   (inputParameters                ), intent(inout)           :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(massFunctionIncompletenessClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (massFunctionIncompletenessClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (massFunctionIncompletenessClass)                          , intent(inout) &
&  :: self
 type     (varying_string                ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                         )                          , intent(in   ) &
&  :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(massFunctionIncompletenessClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(massFunctionIncompletenessClass), intent(inout) :: self
 class(massFunctionIncompletenessClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (massFunctionIncompletenessClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`completeness` Return the completeness of the observational sample at the given mass. Must have the following interface:

```
double precision function myImplementationCompleteness(self,mass)
 class           (massFunctionIncompletenessClass), intent(inout) :: self
 double precision                                 , intent(in   ) :: mass
end double precision function myImplementationCompleteness
```

Existing implementations are:

`massFunctionIncompletenessSurfaceBrightness` Computes incompleteness assuming a normal distribution of surface brightnesses. See §12.31.2.

`massFunctionIncompletenessComplete` Computes incompleteness for a complete survey. See §12.31.1.

Merger Mass Movements

Additional implementations for merger mass movements are added using the `mergerMassMovements` class. The implementation should be placed in a file containing the directive:

```
!# <mergerMassMovements name="mergerMassMovementsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerMassMovements>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerMassMovementsMyImplementation`. The file *must* define a type that extends the `mergerMassMovementsClass` class (or extends another type which is itself an extension of the `mergerMassMovementsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerMassMovementsClass), intent(inout)          :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerMassMovementsClass), intent(inout)          :: self
 type   (inputParameters         ), intent(inout)          :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerMassMovementsClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerMassMovementsClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerMassMovementsClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerMassMovementsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`get` Determine movements of mass during mergers. Must have the following interface:

```
subroutine myImplementationGet(self,node,destinationGasSatellite, &
&  destinationStarsSatellite, destinationGasHost, destinationStarsHost,mergerIsMajor)
 class  (mergerMassMovementsClass), intent(inout) :: self
 type   (treeNode                ), intent(inout) :: node
 integer                          , intent(  out) :: destinationGasSatellite, &
&  destinationStarsSatellite, destinationGasHost, destinationStarsHost
 logical                          , intent(  out) :: mergerIsMajor
end subroutine myImplementationGet
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerMassMovementsClass), intent(inout) :: self
 class(mergerMassMovementsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerMassMovementsClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerMassMovementsBaugh2005` A merger mass movements class which uses a simple calculation.

`mergerMassMovementsVerySimple` A merger mass movements class which uses a simple calculation.

`mergerMassMovementsSimple` A merger mass movements class which uses a simple calculation.

Merger Progenitor Properties

Additional implementations for merger progenitor properties are added using the `mergerProgenitorProperties` class. The implementation should be placed in a file containing the directive:

```
!# <mergerProgenitorProperties name="mergerProgenitorPropertiesMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerProgenitorProperties>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerProgenitorPropertiesMyImplementation`. The file *must* define a type that extends the `mergerProgenitorPropertiesClass` class (or extends another type which is itself an extension of the `mergerProgenitorPropertiesClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerProgenitorPropertiesClass), intent(inout)          :: self
  logical                                 , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerProgenitorPropertiesClass), intent(inout)          :: self
 type   (inputParameters                ), intent(inout)          :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerProgenitorPropertiesClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerProgenitorPropertiesClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerProgenitorPropertiesClass)                          , intent(inout) &
&  :: self
 type     (varying_string                ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                         )                          , intent(in   ) &
&  :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerProgenitorPropertiesClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`get` alculates progenitor properties for merger calculations. Must have the following interface:

```
subroutine myImplementationGet(self,nodeSatellite            , nodeHost,massSatellite  &
&           , massHost,massSpheroidSatellite    , massSpheroidHost,&
&  massSpheroidHostPreMerger, radiusSatellite,radiusHost               , &
&  factorAngularMomentum,massSpheroidRemnant      , massGasSpheroidRemnant)
 class           (mergerProgenitorPropertiesClass), intent(inout)         :: self
 type            (treeNode                       ), intent(inout), target :: &
&  nodeSatellite, nodeHost
 double precision                                  , intent(  out)         :: &
&  massSatellite, massHost
 double precision                                  , intent(  out)         :: &
&  massSpheroidSatellite, massSpheroidHost
 double precision                                  , intent(  out)         :: &
&  massSpheroidHostPreMerger, radiusSatellite
 double precision                                  , intent(  out)         :: radiusHost&
&  , factorAngularMomentum
 double precision                                  , intent(  out)         :: &
&  massSpheroidRemnant, massGasSpheroidRemnant
end subroutine myImplementationGet
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerProgenitorPropertiesClass), intent(inout) :: self
 class(mergerProgenitorPropertiesClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerProgenitorPropertiesClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
```

```
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerProgenitorPropertiesSimple` A merger progenitor properties class which uses a simple calculation.

`mergerProgenitorPropertiesCole2000` A merger progenitor properties class which uses the algorithm of Cole et al. [2000].

`mergerProgenitorPropertiesStandard` A merger progenitor properties class which uses a standard calculation.

Merger Remnant Sizes

Additional implementations for merger remnant sizes are added using the `mergerRemnantSize` class. The implementation should be placed in a file containing the directive:

```
!# <mergerRemnantSize name="mergerRemnantSizeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerRemnantSize>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerRemnantSize-MyImplementation`. The file *must* define a type that extends the `mergerRemnantSizeClass` class (or extends another type which is itself an extension of the `mergerRemnantSizeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerRemnantSizeClass), intent(inout)           :: self
  logical                        , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerRemnantSizeClass), intent(inout)           :: self
 type   (inputParameters       ), intent(inout)           :: descriptor
 logical                        , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerRemnantSizeClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerRemnantSizeClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerRemnantSizeClass)                              , intent(inout) :: self
 type     (varying_string        ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                              , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerRemnantSizeClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`get` Determine merger remnant size and related properties. Must have the following interface:

```
subroutine myImplementationGet(self,node,radius, velocityCircular, &
&  angularMomentumSpecific)
 class           (mergerRemnantSizeClass), intent(inout) :: self
 type            (treeNode              ), intent(inout) :: node
 double precision                         , intent(  out) :: radius, velocityCircular, &
&  angularMomentumSpecific
 end subroutine myImplementationGet
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerRemnantSizeClass), intent(inout) :: self
 class(mergerRemnantSizeClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerRemnantSizeClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerRemnantSizeCovington2008` A merger remnant size class which uses the Cole et al. [2000] algorithm.

`mergerRemnantSizeNull` A merger remnant size class which takes no action.

`mergerRemnantSizeCole2000` A merger remnant size class which uses the Cole et al. [2000] algorithm.

Merger Tree Branching Probabilities

Additional implementations for merger tree branching probabilities are added using the `mergerTreeBranchingProbability` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeBranchingProbability name="mergerTreeBranchingProbabilityMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeBranchingProbability>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeBranchingProbabilityMyImplementation`. The file *must* define a type that extends the `mergerTreeBranchingProbabilityClass` class (or extends another type which is itself an extension of the `mergerTreeBranchingProbabilityClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`massBranch` Returns the mass of a new halo created by a branching event. Must have the following interface:

```
 double precision function myImplementationMassBranch(self,haloMass             , &
&  deltaCritical, massResolution, probabilityFraction,randomNumberGenerator,node)
  class           (mergerTreeBranchingProbabilityClass), intent(inout)         :: self
  double precision                                     , intent(in   )         :: &
&  haloMass, deltaCritical, massResolution, probabilityFraction
  type            (pseudoRandom                       ), intent(inout)         :: &
&  randomNumberGenerator
  type            (treeNode                           ), intent(inout), target :: node
 end double precision function myImplementationMassBranch
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerTreeBranchingProbabilityClass), intent(inout)          :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeBranchingProbabilityClass), intent(inout)          :: self
 type   (inputParameters                    ), intent(inout)          :: descriptor
 logical                                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`stepMaximum` Returns the maximum step in "time" allowed by this algorithm. Must have the following interface:

```
 double precision function myImplementationStepMaximum(self,haloMass, deltaCritical, &
&  massResolution)
  class           (mergerTreeBranchingProbabilityClass), intent(inout) :: self
  double precision                                     , intent(in   ) :: haloMass, &
&  deltaCritical, massResolution
 end double precision function myImplementationStepMaximum
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeBranchingProbabilityClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBranchingProbabilityClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`probability` Computes the probability per unit "time" that a branching event occurs. Must have the following interface:

```
 double precision function myImplementationProbability(self,haloMass, deltaCritical, &
&  massResolution,node)
  class           (mergerTreeBranchingProbabilityClass), intent(inout)         :: self
  double precision                                     , intent(in   )         :: &
&  haloMass, deltaCritical, massResolution
  type            (treeNode                          ), intent(inout), target :: node
 end double precision function myImplementationProbability
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeBranchingProbabilityClass)                          , intent(&
&  inout) :: self
 type     (varying_string                    ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                             )                          , intent(in  &
&   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeBranchingProbabilityClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeBranchingProbabilityClass), intent(inout) :: self
 class(mergerTreeBranchingProbabilityClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`probabilityBound` Computes a bound (upper or lower) to the probability per unit "time" that a branching event occurs. Must have the following interface:

```
double precision function myImplementationProbabilityBound(self,haloMass, deltaCritical&
&  , massResolution,bound,node)
 class           (mergerTreeBranchingProbabilityClass), intent(inout)         :: self
 double precision                                     , intent(in   )         :: &
&  haloMass, deltaCritical, massResolution
 integer                                              , intent(in   )         :: bound
 type            (treeNode                           ), intent(inout), target :: node
end double precision function myImplementationProbabilityBound
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBranchingProbabilityClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`fractionSubresolution` Computes the fraction of subresolution mass accreted per unit "time" Must have the following interface:

```
double precision function myImplementationFractionSubresolution(self,haloMass, &
&  deltaCritical, massResolution,node)
 class           (mergerTreeBranchingProbabilityClass), intent(inout)         :: self
```

```
  double precision                                        , intent(in   )         :: &
&  haloMass, deltaCritical, massResolution
  type            (treeNode                             ), intent(inout), target :: node
 end double precision function myImplementationFractionSubresolution
```

Existing implementations are:

`mergerTreeBranchingProbabilityParkinsonColeHelly` Merger tree branching probabilities using the algorithm of Parkinson et al. [2008]..

`mergerTreeBranchingProbabilityGnrlzdPrssSchchtr` Merger tree branching probabilities using a generalized Press-Schechter approach.

Modifiers for merger tree branching probabilities

Additional implementations for modifiers for merger tree branching probabilities are added using the `mergerTreeBranchingProbabilityModifier` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeBranchingProbabilityModifier name="mergerTreeBranchingProbabilityModifierMyImplementation"
!# <description>A short description of the implementation.</description>
!# </mergerTreeBranchingProbabilityModifier>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeBranchingProbabilityModifierMyImplementation`. The file *must* define a type that extends the `mergerTreeBranchingProbabilityModifierClass` class (or extends another type which is itself an extension of the `mergerTreeBranchingProbabilityModifierClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerTreeBranchingProbabilityModifierClass), intent(inout)           :: self
  logical                                             , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (mergerTreeBranchingProbabilityModifierClass), intent(inout)           :: self
  type   (inputParameters                             ), intent(inout)           :: &
&  descriptor
  logical                                             , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`rateModifier` Return the multiplicative modifier to the tree branch probability rate. Must have the following interface:

```
 double precision function myImplementationRateModifier(self,deltaParent, sigmaChild, &
&  sigmaParent)
  class           (mergerTreeBranchingProbabilityModifierClass), intent(inout) :: self
  double precision                                             , intent(in   ) :: &
&  deltaParent, sigmaChild, sigmaParent
 end double precision function myImplementationRateModifier
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(mergerTreeBranchingProbabilityModifierClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (mergerTreeBranchingProbabilityModifierClass), intent(inout) :: self
  integer                                             , intent(in   ) :: stateFile
  type   (fgsl_file                                  ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                   ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (mergerTreeBranchingProbabilityModifierClass)                          , &
&  intent(inout) :: self
  type     (varying_string                             ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
  character(len=*                                      )                          , &
&  intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(mergerTreeBranchingProbabilityModifierClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(mergerTreeBranchingProbabilityModifierClass), intent(inout) :: self
  class(mergerTreeBranchingProbabilityModifierClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBranchingProbabilityModifierClass), intent(inout) :: self
 integer                                             , intent(in   ) :: stateFile
 type   (fgsl_file                                   ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                    ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeBranchingProbabilityModifierIdentity` Provides a merger tree branching probability rate modifier which always returns the identity modifier.

`mergerTreeBranchingProbabilityModifierParkinson2008` Provides a merger tree branching probability rate modifier which uses the model of Parkinson et al. [2008].

Merger Tree Mass Distributions

Additional implementations for merger tree mass distributions are added using the `mergerTreeBuildMassDistribution` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeBuildMassDistribution name="mergerTreeBuildMassDistributionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeBuildMassDistribution>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeBuildMassDistributionMyImplementation`. The file *must* define a type that extends the `mergerTreeBuildMassDistributionClass` class (or extends another type which is itself an extension of the `mergerTreeBuildMassDistributionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeBuildMassDistributionClass), intent(inout)           :: self
 logical                                      , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeBuildMassDistributionClass), intent(inout)           :: self
```

```
     type   (inputParameters                    ), intent(inout)          :: descriptor
     logical                                     , intent(in   ), optional :: &
    &  includeMethod
     end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeBuildMassDistributionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBuildMassDistributionClass), intent(inout) :: self
 integer                                      , intent(in   ) :: stateFile
 type   (fgsl_file                            ), intent(in   ) :: fgslStateFile
 integer(c_size_t                             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeBuildMassDistributionClass)                          , intent(&
&  inout) :: self
 type     (varying_string                      ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                               )                          , intent(in &
&    ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeBuildMassDistributionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeBuildMassDistributionClass), intent(inout) :: self
 class(mergerTreeBuildMassDistributionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`sample` Returns the sampling rate for merger trees of the given `mass`, per decade of halo mass. Must have the following interface:

```
 double precision function myImplementationSample(self,mass,time,massMinimum,massMaximum&
&  )
  class           (mergerTreeBuildMassDistributionClass), intent(inout) :: self
  double precision                                      , intent(in   ) :: mass, time, &
&  massMinimum, massMaximum
 end double precision function myImplementationSample
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBuildMassDistributionClass), intent(inout) :: self
 integer                                      , intent(in   ) :: stateFile
 type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
 integer(c_size_t                            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeBuildMassDistributionStllrMssFnctn` A merger tree halo mass function sampling class optimized to minimize variance in the model stellar mass function.

`mergerTreeBuildMassDistributionPowerLaw` A merger tree halo mass function sampling class in which the sampling rate is given by a power-law in halo mass.

`mergerTreeBuildMassDistributionHaloMassFunction` A merger tree halo mass function sampling class in which the sampling rate is proportional to the halo mass function.

`mergerTreeBuildMassDistributionGaussian` A merger tree halo mass function sampling class in which the sampling rate is given by a Gaussian distribution in halo mass.

Merger Tree Build Masses

Additional implementations for merger tree build masses are added using the `mergerTreeBuildMasses` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeBuildMasses name="mergerTreeBuildMassesMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeBuildMasses>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeBuildMassesMyImplementation`. The file *must* define a type that extends the `mergerTreeBuildMassesClass` class (or extends another type which is itself an extension of the `mergerTreeBuildMassesClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerTreeBuildMassesClass), intent(inout)          :: self
  logical                            , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeBuildMassesClass), intent(inout)          :: self
 type   (inputParameters           ), intent(inout)          :: descriptor
 logical                            , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeBuildMassesClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBuildMassesClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeBuildMassesClass)                          , intent(inout) :: &
&  self
 type     (varying_string            ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                     )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`construct` Returns a set of merger tree masses (and either their weights, or corresponding mass interval) to be built. Must have the following interface:

```
subroutine myImplementationConstruct(self,time,mass, massMinimum, massMaximum, weight)
 class           (mergerTreeBuildMassesClass)                          , intent(inout)&
&   :: self
 double precision                                                      , intent(in   )&
&   :: time
 double precision                           , allocatable, dimension(:), intent(  out)&
&   :: mass, massMinimum, massMaximum, weight
 end subroutine myImplementationConstruct
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeBuildMassesClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeBuildMassesClass), intent(inout) :: self
 class(mergerTreeBuildMassesClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBuildMassesClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeBuildMassesSampledDistribution` A merger tree masses class which samples masses from a distribution.

`mergerTreeBuildMassesReadHDF5` A merger tree masses class which reads masses from an HDF5 file.

`mergerTreeBuildMassesFixedMass` A merger tree masses class which uses a fixed mass for trees.

`mergerTreeBuildMassesSampledDistributionQuasiRandom` A merger tree masses class which samples masses from a distribution using quasi-random sampling.

`mergerTreeBuildMassesReadXML` A merger tree masses class which reads masses from an XML file.

`mergerTreeBuildMassesSampledDistributionUniform` A merger tree masses class which samples masses from a distribution uniformly.

`mergerTreeBuildMassesUnion` A merger tree masses class which constructs the union of other classes.

`mergerTreeBuildMassesRead` A merger tree masses class which samples masses from a distribution.

`mergerTreeBuildMassesSampledDistributionPseudoRandom` A merger tree masses class which samples masses from a distribution using pseudo-random sampling.

Merger Tree Builders

Additional implementations for merger tree builders are added using the `mergerTreeBuilder` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeBuilder name="mergerTreeBuilderMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeBuilder>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeBuilderMyImplementation`. The file *must* define a type that extends the `mergerTreeBuilderClass` class (or extends another type which is itself an extension of the `mergerTreeBuilderClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeBuilderClass), intent(inout)          :: self
 logical                        , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeBuilderClass), intent(inout)          :: self
 type   (inputParameters       ), intent(inout)          :: descriptor
 logical                        , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeBuilderClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBuilderClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeBuilderClass)                          , intent(inout) :: self
 type     (varying_string        ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`build` Builds and returns a merger tree given the root `node`. Must have the following interface:

```
subroutine myImplementationBuild(self,tree)
 class(mergerTreeBuilderClass), intent(inout)         :: self
 type (mergerTree            ), intent(inout), target :: tree
end subroutine myImplementationBuild
```

`timeEarliestSet` Set the earliest time for the builder to the given value. Must have the following interface:

```
subroutine myImplementationTimeEarliestSet(self,timeEarliest)
 class           (mergerTreeBuilderClass), intent(inout) :: self
 double precision                        , intent(in   ) :: timeEarliest
end subroutine myImplementationTimeEarliestSet
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeBuilderClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeBuilderClass), intent(inout) :: self
 class(mergerTreeBuilderClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeBuilderClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeBuilderCole2000` Merger trees are built using the algorithm of Cole et al. [2000].

Merger Tree Constructors

Additional implementations for merger tree constructors are added using the `mergerTreeConstructor` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeConstructor name="mergerTreeConstructorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeConstructor>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeConstructorMyImplementation`. The file *must* define a type that extends the `mergerTreeConstructorClass` class (or extends another type which is itself an extension of the `mergerTreeConstructorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeConstructorClass), intent(inout)           :: self
 logical                            , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeConstructorClass), intent(inout)           :: self
 type   (inputParameters           ), intent(inout)           :: descriptor
 logical                            , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeConstructorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeConstructorClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeConstructorClass)                          , intent(inout) :: &
&  self
 type     (varying_string            ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                     )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`construct` Construct the merger tree corresponding to the given `treeNumber`. Must have the following interface:

```
type(mergerTree), pointer function myImplementationConstruct(self,treeNumber)
 class  (mergerTreeConstructorClass), intent(inout) :: self
 integer(c_size_t                  ), intent(in   ) :: treeNumber
end type(mergerTree), pointer function myImplementationConstruct
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeConstructorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeConstructorClass), intent(inout) :: self
 class(mergerTreeConstructorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeConstructorClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeConstructorFullySpecified` Merger tree constructor class which constructs a merger tree given a full specification in XML.

`mergerTreeConstructorRead` Merger tree constructor class which builds merger trees assuming smooth accretion. See §12.32.1.

`mergerTreeConstructorStateRestored` Merger tree constructor class which constructs a merger tree by restoring state from file.

`mergerTreeConstructorSmoothAccretion` Merger tree constructor class which builds merger trees assuming smooth accretion.

`mergerTreeConstructorBuild` Merger tree constructor class which builds merger trees.

Merger Tree Evolution Timesteps

Additional implementations for merger tree evolution timesteps are added using the `mergerTreeEvolveTimestep` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeEvolveTimestep name="mergerTreeEvolveTimestepMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeEvolveTimestep>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeEvolveTimestepMyImplementation`. The file *must* define a type that extends the `mergerTreeEvolveTimestepClass` class (or extends another type which is itself an extension of the `mergerTreeEvolveTimestepClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeEvolveTimestepClass), intent(inout)           :: self
 logical                               , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeEvolveTimestepClass), intent(inout)           :: self
 type   (inputParameters              ), intent(inout)           :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeEvolveTimestepClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeEvolveTimestepClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (mergerTreeEvolveTimestepClass)                          , intent(inout) :: &
&  self
  type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeEvolveTimestepClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeEvolveTimestepClass), intent(inout) :: self
 class(mergerTreeEvolveTimestepClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeEvolveTimestepClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`timeEvolveTo` Return the time to which the node can be evolved. Must have the following interface:

```
 double precision function myImplementationTimeEvolveTo(self,node,task,taskSelf,report,&
&  lockNode,lockType)
  class    (mergerTreeEvolveTimestepClass), intent(inout)          :: self
  type     (treeNode                     ), intent(inout), target  :: node
  procedure(timestepTask                 ), intent(  out), pointer :: task
  class    (*                            ), intent(  out), pointer :: taskSelf
  logical                                  , intent(in   )          :: report
  type     (treeNode                     ), intent(  out), pointer :: lockNode
  type     (varying_string               ), intent(  out)          :: lockType
 end double precision function myImplementationTimeEvolveTo
```

Existing implementations are:

`mergerTreeEvolveTimestepMulti` A merger tree evolution timestepping class which takes the minimum over multiple other timesteppers.

`mergerTreeEvolveTimestepRecordEvolution` A merger tree evolution timestepping class which limits the step to the next epoch at which to record evolution of the main branch galaxy. See §8.1.3.

`mergerTreeEvolveTimestepHistory` A merger tree evolution timestepping class which limits the step the next epoch at which to store global history. See §8.1.3.

`mergerTreeEvolveTimestepSimple` A merger tree evolution timestepping class which limits the step to a fraction of the current time or an absolute step, whichever is smaller. See §8.1.2.

`mergerTreeEvolveTimestepSatellite` A merger tree evolution timestepping class which limits the step to the next satellite merger. See §8.1.2.

`mergerTreeEvolveTimestepStandard` A merger tree evolution timestepping class which limits the step to the minimum of that given by the `simple` and `satellite` timesteps.

Merger Tree Evolvers

Additional implementations for merger tree evolvers are added using the `mergerTreeEvolver` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeEvolver name="mergerTreeEvolverMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeEvolver>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeEvolverMyImplementation`. The file *must* define a type that extends the `mergerTreeEvolverClass` class (or extends another type which is itself an extension of the `mergerTreeEvolverClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerTreeEvolverClass), intent(inout)           :: self
  logical                        , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (mergerTreeEvolverClass), intent(inout)           :: self
  type   (inputParameters       ), intent(inout)           :: descriptor
  logical                        , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(mergerTreeEvolverClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeEvolverClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`evolve` Evolve a merger tree. Must have the following interface:

```
 subroutine myImplementationEvolve(self,tree,timeEnd,treeDidEvolve     , suspendTree,&
&  deadlockReporting,systemClockMaximum,initializationLock,status)
  class           (mergerTreeEvolverClass), intent(inout)           :: self
  type            (mergerTree            ), intent(inout), target   :: tree
  double precision                         , intent(in   )           :: timeEnd
  logical                                  , intent(  out)           :: treeDidEvolve, &
&  suspendTree
  logical                                  , intent(in   )           :: deadlockReporting
  integer         (kind_int8             ), intent(in   ), optional :: &
&  systemClockMaximum
  integer         (omp_lock_kind         ), intent(inout), optional :: &
&  initializationLock
  integer                                  , intent(  out), optional :: status
 end subroutine myImplementationEvolve
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (mergerTreeEvolverClass)                          , intent(inout) :: self
  type     (varying_string        ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                 )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeEvolverClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeEvolverClass), intent(inout) :: self
 class(mergerTreeEvolverClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeEvolverClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeEvolverNonEvolving` A non-evolving merger tree evolver.

`mergerTreeEvolverStandard` The standard merger tree evolver.

Merger Tree Importer

Additional implementations for merger tree importer are added using the `mergerTreeImporter` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeImporter name="mergerTreeImporterMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeImporter>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeImporterMyImplementation`. The file *must* define a type that extends the `mergerTreeImporterClass` class (or extends another type which is itself an extension of the `mergerTreeImporterClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`positionsAvailable` Return true if positions and/or velocities are available. Must have the following interface:

```
logical function myImplementationPositionsAvailable(self,positions, velocities)
 class  (mergerTreeImporterClass), intent(inout) :: self
 logical                         , intent(in   ) :: positions, velocities
end logical function myImplementationPositionsAvailable
```

`treesAreSelfContained` Returns a Boolean integer specifying whether trees are self-contained. Must have the following interface:

```
integer function myImplementationTreesAreSelfContained(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end integer function myImplementationTreesAreSelfContained
```

`cubeLength` Returns the length of the simulation cube. Must have the following interface:

```
double precision function myImplementationCubeLength(self,time,status)
 class           (mergerTreeImporterClass), intent(inout)           :: self
 double precision                         , intent(in   )           :: time
 integer                                  , intent(  out), optional :: status
end double precision function myImplementationCubeLength
```

`nodeCount` Returns the number of nodes in the $i^{\rm th}$ tree. Must have the following interface:

```
integer(kind=c_size_t) function myImplementationNodeCount(self,i)
 class  (mergerTreeImporterClass), intent(inout) :: self
 integer                         , intent(in   ) :: i
end integer(kind=c_size_t) function myImplementationNodeCount
```

`angularMomentaIncludeSubhalos` Returns a Boolean specifying whether halo angular momenta (or spins) include the contribution from their subhalos. Must have the following interface:

```
logical function myImplementationAngularMomentaIncludeSubhalos(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationAngularMomentaIncludeSubhalos
```

`positionsArePeriodic` Returns a Boolean integer specifying whether positions are periodic. Must have the following interface:

```
integer function myImplementationPositionsArePeriodic(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end integer function myImplementationPositionsArePeriodic
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeImporterClass), intent(inout)           :: self
 type   (inputParameters        ), intent(inout)           :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeImporterClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`particleCountAvailable` Return true if particle counts are available. Must have the following interface:

```
logical function myImplementationParticleCountAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationParticleCountAvailable
```

`treeCount` Returns a count of the number of trees available. Must have the following interface:

```
integer(kind=c_size_t) function myImplementationTreeCount(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end integer(kind=c_size_t) function myImplementationTreeCount
```

`massesIncludeSubhalos` Returns a Boolean specifying whether halo masses include the contribution from their subhalos. Must have the following interface:

```
logical function myImplementationMassesIncludeSubhalos(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationMassesIncludeSubhalos
```

`open` Opens the file. Must have the following interface:

```
subroutine myImplementationOpen(self,fileName)
 class(mergerTreeImporterClass), intent(inout) :: self
 type (varying_string         ), intent(in   ) :: fileName
end subroutine myImplementationOpen
```

`angularMomentaAvailable` Return true if angular momenta (magnitudes) are available. Must have the following interface:

```
logical function myImplementationAngularMomentaAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationAngularMomentaAvailable
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeImporterClass), intent(inout) :: self
 class(mergerTreeImporterClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeImporterClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`treesHaveSubhalos` Returns a Boolean integer specifying whether or not the trees have subhalos. Must have the following interface:

```
integer function myImplementationTreesHaveSubhalos(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end integer function myImplementationTreesHaveSubhalos
```

`angularMomenta3DAvailable` Return true if angular momenta (vectors) are available. Must have the following interface:

```
logical function myImplementationAngularMomenta3DAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationAngularMomenta3DAvailable
```

`subhaloTraceCount` Returns the length of a node's subhalo trace. Must have the following interface:

```
integer(kind=c_size_t) function myImplementationSubhaloTraceCount(self,node)
 class(mergerTreeImporterClass), intent(inout) :: self
 class(nodeData               ), intent(in   ) :: node
end integer(kind=c_size_t) function myImplementationSubhaloTraceCount
```

`velocitiesIncludeHubbleFlow` Returns a Boolean integer specifying whether velocities include the Hubble flow. Must have the following interface:

```
integer function myImplementationVelocitiesIncludeHubbleFlow(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end integer function myImplementationVelocitiesIncludeHubbleFlow
```

`close` Closes the file. Must have the following interface:

```
subroutine myImplementationClose(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end subroutine myImplementationClose
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`canReadSubsets` Returns true if arbitrary subsets of halos from a forest can be read. Must have the following interface:

```
logical function myImplementationCanReadSubsets(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationCanReadSubsets
```

`treeWeight` Returns the weight to assign to the $i^{\rm th}$ tree. Must have the following interface:

```
double precision function myImplementationTreeWeight(self,i)
 class  (mergerTreeImporterClass), intent(inout) :: self
 integer                         , intent(in   ) :: i
end double precision function myImplementationTreeWeight
```

`velocityDispersionAvailable` Return true if halo velocity dispersions are available. Must have the following interface:

```
logical function myImplementationVelocityDispersionAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationVelocityDispersionAvailable
```

`scaleRadiiAvailable` Return true if scale radii are available. Must have the following interface:

```
logical function myImplementationScaleRadiiAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationScaleRadiiAvailable
```

`treeIndex` Returns the index of the $i^{\rm th}$ tree. Must have the following interface:

```
integer(kind=kind_int8) function myImplementationTreeIndex(self,i)
 class  (mergerTreeImporterClass), intent(inout) :: self
 integer                         , intent(in   ) :: i
end integer(kind=kind_int8) function myImplementationTreeIndex
```

`spinAvailable` Return true if spin (magnitudes) are available. Must have the following interface:

```
logical function myImplementationSpinAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationSpinAvailable
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeImporterClass), intent(inout)           :: self
 logical                         , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`spin3DAvailable` Return true if spin (vectors) are available. Must have the following interface:

```
logical function myImplementationSpin3DAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationSpin3DAvailable
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`subhaloTrace` Supplies epochs, positions, and velocities for traced subhalos. Must have the following interface:

```
subroutine myImplementationSubhaloTrace(self,node,time,position, velocity)
 class           (mergerTreeImporterClass)               , intent(inout) :: self
 class           (nodeData               )               , intent(in   ) :: node
 double precision                         , dimension(:)  , intent(  out) :: time
 double precision                         , dimension(:,:), intent(  out) :: position, &
&  velocity
end subroutine myImplementationSubhaloTrace
```

`velocityMaximumAvailable` Return true if rotation curve velocity maxima are available. Must have the following interface:

```
logical function myImplementationVelocityMaximumAvailable(self)
 class(mergerTreeImporterClass), intent(inout) :: self
end logical function myImplementationVelocityMaximumAvailable
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeImporterClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`import` Imports the $i^{\rm th}$ tree. Must have the following interface:

```
 subroutine myImplementationImport(self,i,nodes,nodeSubset,requireScaleRadii, &
&  requireAngularMomenta, requireAngularMomenta3D, requireSpin, requireSpin3D, &
&  requirePositions, structureOnly,requireNamedReals, requireNamedIntegers)
  class  (mergerTreeImporterClass)                              , intent(inout)           &
&  :: self
  integer                                                       , intent(in   )           &
&  :: i
  class  (nodeDataMinimal       ), allocatable, dimension(:), intent(  out)           &
&  :: nodes
  integer(c_size_t              )             , dimension(:), intent(in   ), optional &
&  :: nodeSubset
  logical                                                       , intent(in   ), optional &
&  :: requireScaleRadii, requireAngularMomenta, requireAngularMomenta3D, requireSpin, &
&  requireSpin3D, requirePositions, structureOnly
  type   (varying_string        )             , dimension(:), intent(in   ), optional &
&  :: requireNamedReals, requireNamedIntegers
 end subroutine myImplementationImport
```

Existing implementations are:

`mergerTreeImporterSussing` Importer for "Sussing Merger Trees" format merger tree files [Srisawat et al., 2013]. See §12.37.2.

`mergerTreeImporterSussingASCII` Importer for "Sussing Merger Trees" ASCII format merger tree files [Srisawat et al., 2013].

`mergerTreeImporterSussingHDF5` Importer for "Sussing Merger Trees" HDF5 format merger tree files (Thomas et al.; in prep.).

`mergerTreeImporterGalacticus` Importer for Galacticus format merger tree files. See §12.37.1.

Merger Tree Building Mass Resolutions

Additional implementations for merger tree building mass resolutions are added using the `mergerTreeMassResolution` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeMassResolution name="mergerTreeMassResolutionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeMassResolution>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeMassResolutionMyImplementation`. The file *must* define a type that extends the `mergerTreeMassResolutionClass` class (or extends another type which is itself an extension of the `mergerTreeMassResolutionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerTreeMassResolutionClass), intent(inout)          :: self
  logical                               , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeMassResolutionClass), intent(inout)          :: self
 type   (inputParameters              ), intent(inout)          :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeMassResolutionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeMassResolutionClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeMassResolutionClass)                          , intent(inout) :: &
&  self
 type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeMassResolutionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`resolution` Gives the mass resolution to use for the given tree. Must have the following interface:

```
double precision function myImplementationResolution(self,tree)
 class(mergerTreeMassResolutionClass), intent(inout) :: self
 type (mergerTree                   ), intent(in   ) :: tree
end double precision function myImplementationResolution
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeMassResolutionClass), intent(inout) :: self
 class(mergerTreeMassResolutionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeMassResolutionClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeMassResolutionScaled` Provides a mass resolution for merger tree building which scales with tree mass. See §12.33.2.

`mergerTreeMassResolutionFixed` Provides a fixed mass resolution for merger tree building. See §12.33.1.

Merger Tree Node Evolvers

Additional implementations for merger tree node evolvers are added using the `mergerTreeNodeEvolver` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeNodeEvolver name="mergerTreeNodeEvolverMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeNodeEvolver>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeNodeEvolverMyImplementation`. The file *must* define a type that extends the `mergerTreeNodeEvolverClass` class (or extends another type which is itself an extension of the `mergerTreeNodeEvolverClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`isAccurate` Return true if a tree node property is within expected accuracy of a given value. Must have the following interface:

```
 logical function myImplementationIsAccurate(self,valueNode, valueExpected)
  class           (mergerTreeNodeEvolverClass), intent(inout) :: self
  double precision                            , intent(in   ) :: valueNode, &
&  valueExpected
 end logical function myImplementationIsAccurate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (mergerTreeNodeEvolverClass), intent(inout)           :: self
  logical                            , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (mergerTreeNodeEvolverClass), intent(inout)           :: self
  type   (inputParameters           ), intent(inout)           :: descriptor
  logical                            , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(mergerTreeNodeEvolverClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (mergerTreeNodeEvolverClass), intent(inout) :: self
  integer                            , intent(in   ) :: stateFile
  type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
  integer(c_size_t                   ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`evolve` Evolve a node merger tree. Must have the following interface:

```
 subroutine myImplementationEvolve(self,tree,node,timeEnd,interrupted,functionInterrupt,&
&  galacticStructureSolver__,systemClockMaximum,status)
  class           (mergerTreeNodeEvolverClass  ), intent(inout)                    :: &
&  self
  type            (mergerTree                  ), intent(inout)                    :: &
&  tree
  type            (treeNode                    ), intent(inout)          , pointer :: &
&  node
  double precision                                , intent(in   )                    :: &
&  timeEnd
```

```
  logical                                          , intent(  out)                   :: &
&  interrupted
  procedure       (interruptTask               ), intent(  out)          , pointer :: &
&  functionInterrupt
  class           (galacticStructureSolverClass), intent(in   ), target            :: &
&  galacticStructureSolver__
  integer         (kind_int8                   ), intent(in   ), optional          :: &
&  systemClockMaximum
  integer                                          , intent(  out), optional          :: &
&  status
 end subroutine myImplementationEvolve
```

`promote` Promote `node` to its parent node, then destroy it. Must have the following interface:

```
subroutine myImplementationPromote(self,node)
 class(mergerTreeNodeEvolverClass), intent(inout)          :: self
 type (treeNode                  ), intent(inout), pointer :: node
end subroutine myImplementationPromote
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeNodeEvolverClass)                          , intent(inout) :: &
&  self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`merge` Handles instances where `node` is about to merge with its parent node. Must have the following interface:

```
subroutine myImplementationMerge(self,node)
 class(mergerTreeNodeEvolverClass), intent(inout)          :: self
 type (treeNode                  ), intent(inout), pointer :: node
end subroutine myImplementationMerge
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeNodeEvolverClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeNodeEvolverClass), intent(inout) :: self
 class(mergerTreeNodeEvolverClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeNodeEvolverClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeNodeEvolverStandard` The standard merger tree noe evolver.

Merger Tree Node Merger Processing

Additional implementations for merger tree node merger processing are added using the `mergerTreeNodeMerger` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeNodeMerger name="mergerTreeNodeMergerMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeNodeMerger>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeNode-MergerMyImplementation`. The file *must* define a type that extends the `mergerTreeNodeMergerClass` class (or extends another type which is itself an extension of the `mergerTreeNodeMergerClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeNodeMergerClass), intent(inout)          :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeNodeMergerClass), intent(inout)          :: self
 type   (inputParameters          ), intent(inout)          :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeNodeMergerClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeNodeMergerClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeNodeMergerClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`process` Process the merger between `node` and its parent node, then destroy it. Must have the following interface:

```
subroutine myImplementationProcess(self,node)
 class(mergerTreeNodeMergerClass), intent(inout)          :: self
 type (treeNode                 ), intent(inout), pointer :: node
end subroutine myImplementationProcess
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeNodeMergerClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeNodeMergerClass), intent(inout) :: self
 class(mergerTreeNodeMergerClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeNodeMergerClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeNodeMergerSingleLevelHierarchy` A node merger class implementing a single level hierarchy.

Merger Tree Operators

Additional implementations for merger tree operators are added using the `mergerTreeOperator` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeOperator name="mergerTreeOperatorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeOperator>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeOperatorMyImplementation`. The file *must* define a type that extends the `mergerTreeOperatorClass` class (or extends another type which is itself an extension of the `mergerTreeOperatorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`operate` Perform an operation on the merger tree. Must have the following interface:

```
subroutine myImplementationOperate(self,tree)
 class(mergerTreeOperatorClass), intent(inout)         :: self
 type (mergerTree             ), intent(inout), target :: tree
end subroutine myImplementationOperate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeOperatorClass), intent(inout)           :: self
 logical                         , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeOperatorClass), intent(inout)           :: self
 type   (inputParameters        ), intent(inout)           :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeOperatorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeOperatorClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeOperatorClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeOperatorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeOperatorClass), intent(inout) :: self
 class(mergerTreeOperatorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeOperatorClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`finalize` Finalize a merger tree operator. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationFinalize(self)
 class(mergerTreeOperatorClass), intent(inout) :: self
end subroutine myImplementationFinalize
```

Existing implementations are:

`mergerTreeOperatorRegridTimes` Provides a merger tree operator which restructures the tree onto a fixed grid of timesteps.

`mergerTreeOperatorAugment` Provides a merger tree operator which augments tree resolution by inserting high-resolution branches.

`mergerTreeOperatorSelectWithinRange` Provides a select-within-range operator on the base nodes of merger trees.

`mergerTreeOperatorSequence` Provides a sequence of operators on merger trees.

`mergerTreeOperatorPruneClones` Provides a clone pruning operator on merger trees.

`mergerTreeOperatorMonotonizeMassGrowth` A merger tree operator which makes mass growth along merger tree branches monotonic.

`mergerTreeOperatorDeforest` Provides a deforestation operator for merger trees. Given a forest, this operator will destroy all but the first tree in the forest.

`mergerTreeOperatorPruneByTime` Provides a merger tree operator which prunes branches to end at a fixed time.

`mergerTreeOperatorPerturbMasses` A merger tree operator which perturbs halo masses by some error model.

`mergerTreeOperatorPruneLightcone` Provides a pruning-by-lightcone operator on merger trees. Trees which have no nodes which lie within the lightcone are completely pruned away.

`mergerTreeOperatorPruneBranchTips` Cmplements a merger tree operator which prunes tips of branches (i.e. sections from the leaf node to the first node with a sibling).

`mergerTreeOperatorPruneHierarchy` Contains a module which implements a merger tree operator which prunes branches below a given level in the substructure hierarchy. In any tree, the primary progenitor of the base node has substructure hierarchy depth 0. A branch which connects directly to this primary progenitor branch has substructure hierarchy depth 1, while a branch which connects directly to that branch has substructure hierarchy depth 2, and so on. The tree is pruned of all branches of hierarchy depth equal to or greater than the value provided by the `[hierarchyDepth]` parameter.

`mergerTreeOperatorPruneBaryons` Provides a pruning operator on merger trees that removes all branches that can not contain any baryons.

`mergerTreeOperatorProfiler` A merger tree operator which profiles merger tree structure.

`mergerTreeOperatorAssignOrbits` Provides a merger tree operator which assigns orbits to non-primary progenitor nodes.

`mergerTreeOperatorConditionalMF` Provides a merger tree operator which accumulates conditional mass functions for trees. In addition to the cumulative mass function, $1^{\rm st}$ through $n^{\rm th}$ most-massive progenitor mass functions, formation rate functions, and unevolved subhalo mass functions [Jiang and van den Bosch, 2014] split by hierarchy depth are computed and output. Mass functions are accumulated in logarithmically-spaced bins of parent halo mass, logarithmically-spaced bins of mass ratio (the ratio of progenitor to parent halo mass), and at pairs of parent/progenitor redshifts. The following parameters control the operator:

`parentMassCount` The number of bins in parent halo mass to use;

`parentMassMinimum` The minimum parent halo mass to consider;

`parentMassMaximum` The maximum parent halo mass to consider;

`massRatioCount` The number of bins in mass ratio to use;

`massRatioMinimum` The minimum mass ratio to consider;

`massRatioMaximum` The maximum mass ratio to consider;

`parentRedshifts` A list of redshifts at which to identify parent halos;

`progenitorRedshifts` A corresponding list of redshifts at which to identify progenitor halos;

`primaryProgenitorDepth` The number of $i^{\rm th}$ most-massive progenitor mass functions to compute (starting from the $1^{\rm st}$ most-massive);

`subhaloHierarchyDepth` The maximum depth in the subhalo hierarchy for which to compute the unevolved subhalo mass function;

`formationRateTimeFraction` The fraction of the current time over which to estimate the formation rate of halos when computing merger tree statistics;

`outputGroupName` The name of the hierarchical data format (HDF5) group to which mass functions will be written.

If the operator finds the named HDF5 group already in existance, it will accumulate its mass functions to those already written to the group, weighting by the inverse of the variance in each bin. The structure of the HDF5 group is as follows:

```

COMMENT "Unevolved subhalo mass function errors []"
DATATYPE  H5T_IEEE_F64LE
DATASPACE  SIMPLE { ( Nhierarchy, Nratio, Nparent ) }
}
}
```

Where `Nratio` is the number of bins in mass ratio, `Nparent` is the number of bins in mass ratio, `Nz` is the number of parent/progenitor redshift pairs, `Ndepth` is the maximum depth in the ranking of most-massive progenitor mass functions, `Nhierarchy` is the maximum depth in the subhalo hierarchy for subhalo mass functions. The first dimension of the `formationRateFunction` dataset stores two different versions of the formation rate function. The first uses the mass of the forming halo at the time of formation, the second uses the mass of the node immediately prior to it becoming a subhalo. Mass functions are output as $\mathrm{d}N/\mathrm{d}\log_{10} m$ where N is the number of halos per parent halo, and m is the mass ratio.

`mergerTreeOperatorDumpToGraphViz` Provides a dump to GraphViz operator on merger trees.

`mergerTreeOperatorExport` A merger tree operator which exports merger trees to file.

`mergerTreeOperatorPruneNonEssential` Implements a merger tree operator which prunes branches that do not directly influence an "essential" node. Any branch which does not connect to the branch into which the node identified by ID `[essentialNodeI]` descends by time `essetialNodeTime]` will be pruned.

`mergerTreeOperatorParticulate` Provides a merger tree operator which create particle representations of Galacticus halos.

`mergerTreeOperatorInformationContent` A merger tree operator which computes the cladistic information content Thorley et al. [1998] of merger trees. This is output to a group in the output file with name specified by the `[outputGroupName]` parameter. Two datasets are written to this group: `treeIndex` which gives the index of each tree, and `informationContent` which gives the cladistic information content in units of bits.

`mergerTreeOperatorMassAccretionHistory` A merger tree operator which outputs mass accretion histories. Histories are written into the Galacticus output file in a group with name given by `[outputGroupName]`. Within that group, each merger tree has its own group named `mergerTree< N>` where `< N>` is the tree index. Within each such merger tree group datasets giving the node index ("`nodeIndex`"), time ("`nodeTime`"), basic mass ("`nodeMass`"), expansion factor ("`nodeExpansionFactor`") are written. Optionally, datasets giving the spin parameter ("`nodeSpin`") and its vector components ("`nodeSpinVector`") are included if `[includeSpin]` and `[includeSpinVector]` respectively are set to `true`.

`mergerTreeOperatorNull` Provides a null operator on merger trees.

`mergerTreeOperatorPruneByMass` Provides a pruning-by-mass operator on merger trees.

`mergerTreeOperatorOutputRootMasses` Output a file of tree root masses (and weights).

Merger Tree Outputters

Additional implementations for merger tree outputters are added using the `mergerTreeOutputter` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeOutputter name="mergerTreeOutputterMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeOutputter>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeOutputterMyImplementation`. The file *must* define a type that extends the `mergerTreeOutputterClass` class (or extends another type which is itself an extension of the `mergerTreeOutputterClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeOutputterClass), intent(inout)          :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeOutputterClass), intent(inout)          :: self
 type   (inputParameters         ), intent(inout)          :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeOutputterClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeOutputterClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeOutputterClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`output` Output a merger tree. Must have the following interface:

```
subroutine myImplementationOutput(self,tree,indexOutput,time,isLastOutput)
 class           (mergerTreeOutputterClass), intent(inout)           :: self
 type            (mergerTree              ), intent(inout), target   :: tree
 integer         (c_size_t                ), intent(in   )           :: indexOutput
 double precision                           , intent(in   )           :: time
 logical                                    , intent(in   ), optional :: isLastOutput
end subroutine myImplementationOutput
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeOutputterClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeOutputterClass), intent(inout) :: self
 class(mergerTreeOutputterClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeOutputterClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`reduce` Reduce the object onto another object of the class. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationReduce(self,reduced)
 class(mergerTreeOutputterClass), intent(inout) :: self
 class(mergerTreeOutputterClass), intent(inout) :: reduced
end subroutine myImplementationReduce
```

`finalize` Finalize output of merger trees. Must have the following interface:

```
subroutine myImplementationFinalize(self)
 class(mergerTreeOutputterClass), intent(inout) :: self
end subroutine myImplementationFinalize
```

Existing implementations are:

`mergerTreeOutputterAnalyzer` A merger tree outputter class which performs analyzes on the trees.

`mergerTreeOutputterNull` A merger tree outputter which does no output.

`mergerTreeOutputterStandard` The standard merger tree outputter.

`mergerTreeOutputterMulti` A merger tree outputter which combines multiple other outputters.

Merger Tree Walkers

Additional implementations for merger tree walkers are added using the `mergerTreeWalker` class. The implementation should be placed in a file containing the directive:

```
!# <mergerTreeWalker name="mergerTreeWalkerMyImplementation">
!# <description>A short description of the implementation.</description>
!# </mergerTreeWalker>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `mergerTreeWalkerMyImplementation`. The file *must* define a type that extends the `mergerTreeWalkerClass` class (or extends another type which is itself an extension of the `mergerTreeWalkerClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`next` Update the pointer to the next node to visit. Returns true if such a node exists, returns false if no such node exists (i.e. if all nodes have been visited already). Must have the following interface:

```
logical function myImplementationNext(self,node)
 class(mergerTreeWalkerClass), intent(inout)          :: self
 type (treeNode             ), intent(inout), pointer :: node
end logical function myImplementationNext
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (mergerTreeWalkerClass), intent(inout)           :: self
 logical                       , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (mergerTreeWalkerClass), intent(inout)           :: self
 type   (inputParameters      ), intent(inout)           :: descriptor
 logical                       , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(mergerTreeWalkerClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeWalkerClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (mergerTreeWalkerClass)                          , intent(inout) :: self
 type     (varying_string       ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`nodesRemain` Returns true if more nodes remain to be walked to in the tree. Must have the following interface:

```
logical function myImplementationNodesRemain(self)
 class(mergerTreeWalkerClass), intent(inout) :: self
end logical function myImplementationNodesRemain
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(mergerTreeWalkerClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(mergerTreeWalkerClass), intent(inout) :: self
 class(mergerTreeWalkerClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (mergerTreeWalkerClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`mergerTreeWalkerAllNodesBranch` Provides a merger tree walker which iterates depth-first over all all nodes in a given branch.

`mergerTreeWalkerAllNodes` Provides a merger tree walker which iterates depth-first over all all nodes.

`mergerTreeWalkerTreeConstruction` Provides a merger tree walker for trees under construction.

`mergerTreeWalkerAllAndFormationNodes` Provides a merger tree walker which iterates depth-first over all nodes including formation nodes.

`mergerTreeWalkerIsolatedNodesBranch` Provides a merger tree walker which iterates depth-first over all isolated nodes in a given branch.

`mergerTreeWalkerIsolatedNodes` Provides a merger tree walker which iterates depth-first over all isolated nodes.

Merger Tree Processing Times

Additional implementations for merger tree processing times are added using the `metaTreeProcessingTime` class. The implementation should be placed in a file containing the directive:

```
!# <metaTreeProcessingTime name="metaTreeProcessingTimeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </metaTreeProcessingTime>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `metaTreeProcessingTimeMyImplementation`. The file *must* define a type that extends the `metaTreeProcessingTimeClass` class (or extends another type which is itself an extension of the `metaTreeProcessingTimeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (metaTreeProcessingTimeClass), intent(inout)           :: self
  logical                             , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (metaTreeProcessingTimeClass), intent(inout)           :: self
 type   (inputParameters            ), intent(inout)           :: descriptor
 logical                             , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(metaTreeProcessingTimeClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`time` Return an estimate of the time needed to process a tree of the given mass. Must have the following interface:

```
double precision function myImplementationTime(self,massTree)
 class           (metaTreeProcessingTimeClass), intent(inout) :: self
 double precision                             , intent(in   ) :: massTree
end double precision function myImplementationTime
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (metaTreeProcessingTimeClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (metaTreeProcessingTimeClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(metaTreeProcessingTimeClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(metaTreeProcessingTimeClass), intent(inout) :: self
 class(metaTreeProcessingTimeClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (metaTreeProcessingTimeClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`metaTreeProcessingTimeFile` A merger tree processing time estimator using a polynomial relation read from file.

Model Parameters

Additional implementations for model parameters are added using the `modelParameter` class. The implementation should be placed in a file containing the directive:

```
!# <modelParameter name="modelParameterMyImplementation">
!# <description>A short description of the implementation.</description>
!# </modelParameter>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `modelParameterMyImplementation`. The file *must* define a type that extends the `modelParameterClass` class (or extends another type which is itself an extension of the `modelParameterClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`priorInvert` Invert the prior, returning the parameter value given the cumulative probability. Must have the following interface:

```
double precision function myImplementationPriorInvert(self,f)
 class           (modelParameterClass), intent(inout) :: self
 double precision                     , intent(in   ) :: f
end double precision function myImplementationPriorInvert
```

`priorMaximum` Return the maximum non-zero value of the prior for this parameter. Must have the following interface:

```
double precision function myImplementationPriorMaximum(self)
 class(modelParameterClass), intent(inout) :: self
end double precision function myImplementationPriorMaximum
```

`randomPerturbation` Return a random perturbation for this parameter. Must have the following interface:

```
double precision function myImplementationRandomPerturbation(self)
 class(modelParameterClass), intent(inout) :: self
end double precision function myImplementationRandomPerturbation
```

`priorSample` Sample from the parameter's prior. Must have the following interface:

```
double precision function myImplementationPriorSample(self)
 class(modelParameterClass), intent(inout) :: self
end double precision function myImplementationPriorSample
```

`map` Map the parameter value. Must have the following interface:

```
double precision function myImplementationMap(self,x)
 class           (modelParameterClass), intent(inout) :: self
 double precision                     , intent(in   ) :: x
end double precision function myImplementationMap
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(modelParameterClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`priorMinimum` Return the minimum non-zero value of the prior for this parameter. Must have the following interface:

```
double precision function myImplementationPriorMinimum(self)
 class(modelParameterClass), intent(inout) :: self
end double precision function myImplementationPriorMinimum
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (modelParameterClass), intent(inout)           :: self
 type   (inputParameters    ), intent(inout)           :: descriptor
 logical                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (modelParameterClass), intent(inout)           :: self
 logical                     , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(modelParameterClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`name` Return the name of this parameter. Must have the following interface:

```
type(varying_string) function myImplementationName(self)
 class(modelParameterClass), intent(inout) :: self
end type(varying_string) function myImplementationName
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (modelParameterClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (modelParameterClass)                          , intent(inout) :: self
 type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*              )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`unmap` Unmap the parameter value. Must have the following interface:

```
double precision function myImplementationUnmap(self,x)
 class           (modelParameterClass), intent(inout) :: self
 double precision                     , intent(in   ) :: x
end double precision function myImplementationUnmap
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(modelParameterClass), intent(inout) :: self
 class(modelParameterClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (modelParameterClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`logPrior` Return the log-prior for this parameter. Must have the following interface:

```
double precision function myImplementationLogPrior(self,x)
 class           (modelParameterClass), intent(inout) :: self
 double precision                     , intent(in   ) :: x
end double precision function myImplementationLogPrior
```

Existing implementations are:

`modelParameterInactive` An inactive model parameter class.

`modelParameterDerived` A model parameter class in which the parameter value is derived from other parameters.

`modelParameterActive` An active model parameter class.

N-body Halo Mass Errors

Additional implementations for n-body halo mass errors are added using the `nbodyHaloMassError` class. The implementation should be placed in a file containing the directive:

```
!# <nbodyHaloMassError name="nbodyHaloMassErrorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </nbodyHaloMassError>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `nbodyHaloMassErrorMyImplementation`. The file *must* define a type that extends the `nbodyHaloMassErrorClass` class (or extends another type which is itself an extension of the `nbodyHaloMassErrorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (nbodyHaloMassErrorClass), intent(inout)           :: self
 logical                         , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (nbodyHaloMassErrorClass), intent(inout)           :: self
 type   (inputParameters        ), intent(inout)           :: descriptor
 logical                         , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(nbodyHaloMassErrorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nbodyHaloMassErrorClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (nbodyHaloMassErrorClass)                          , intent(inout) :: self
 type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`errorFractional` Return the fractional error on the mass of an N-body halo corresponding to the given `node`. Must have the following interface:

```
double precision function myImplementationErrorFractional(self,node)
 class(nbodyHaloMassErrorClass), intent(inout) :: self
 type (treeNode               ), intent(inout) :: node
end double precision function myImplementationErrorFractional
```

`correlation` Return the correlation in the error on the mass of a pair of N-body halos corresponding to the given `node1` and `node2`. Must have the following interface:

```
double precision function myImplementationCorrelation(self,node1, node2)
 class(nbodyHaloMassErrorClass), intent(inout) :: self
 type (treeNode               ), intent(inout) :: node1, node2
end double precision function myImplementationCorrelation
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(nbodyHaloMassErrorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(nbodyHaloMassErrorClass), intent(inout) :: self
 class(nbodyHaloMassErrorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`errorZeroAlways` Return `true` if the mass error is always zero for any halo. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationErrorZeroAlways(self)
 class(nbodyHaloMassErrorClass), intent(inout) :: self
end logical function myImplementationErrorZeroAlways
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nbodyHaloMassErrorClass), intent(inout) :: self
 integer                         , intent(in   ) :: stateFile
 type   (fgsl_file              ), intent(in   ) :: fgslStateFile
 integer(c_size_t               ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`nbodyHaloMassErrorTrenti2010` An N-body dark matter halo mass error class using the model of Trenti et al. [2010].

`nbodyHaloMassErrorNull` A null N-body dark matter halo mass error class. Errors are always zero.

`nbodyHaloMassErrorSOHaloFinder` An N-body dark matter halo mass error class which implements a model for errors in spherical overdensity halo finders.

`nbodyHaloMassErrorPowerLaw` An N-body dark matter halo mass error class in which errors are a power-law in halo mass.

`nbodyHaloMassErrorFriendsOfFriends` An N-body dark matter halo mass error class which uses a fit appropriate for friends-of-friends group finders.

N-Body Simulation Data Importer

Additional implementations for n-body simulation data importer are added using the `nbodyImporter` class. The implementation should be placed in a file containing the directive:

```
!# <nbodyImporter name="nbodyImporterMyImplementation">
!# <description>A short description of the implementation.</description>
!# </nbodyImporter>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `nbodyImporterMyImplementation`. The file *must* define a type that extends the `nbodyImporterClass` class (or extends another type which is itself an extension of the `nbodyImporterClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (nbodyImporterClass), intent(inout)           :: self
  logical                    , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (nbodyImporterClass), intent(inout)           :: self
 type   (inputParameters   ), intent(inout)           :: descriptor
 logical                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(nbodyImporterClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nbodyImporterClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (nbodyImporterClass)                          , intent(inout) :: self
 type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*             )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`import` Import position and velocity data from the named N-body data file. Must have the following interface:

```
type(nBodyData) function myImplementationImport(self,fileName,fileNamePrevious)
 class    (nbodyImporterClass), intent(inout)           :: self
 character(len=*             ), intent(in   )           :: fileName
 character(len=*             ), intent(in   ), optional :: fileNamePrevious
end type(nBodyData) function myImplementationImport
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(nbodyImporterClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(nbodyImporterClass), intent(inout) :: self
 class(nbodyImporterClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nbodyImporterClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`nbodyImporterGadgetBinary` An importer for Gadget binary files.

`nbodyImporterGadgetHDF5` An importer for Gadget HDF5 files.

N-Body Simulation Data Operators

Additional implementations for n-body simulation data operators are added using the `nbodyOperator` class. The implementation should be placed in a file containing the directive:

```
!# <nbodyOperator name="nbodyOperatorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </nbodyOperator>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `nbodyOperatorMyImplementation`. The file *must* define a type that extends the `nbodyOperatorClass` class (or extends another type which is itself an extension of the `nbodyOperatorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`operate` Operate on the provided N-body simulation. Must have the following interface:

```
subroutine myImplementationOperate(self,simulation)
 class(nbodyOperatorClass), intent(inout) :: self
 type (nBodyData         ), intent(inout) :: simulation
end subroutine myImplementationOperate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (nbodyOperatorClass), intent(inout)           :: self
  logical                    , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (nbodyOperatorClass), intent(inout)           :: self
 type   (inputParameters   ), intent(inout)           :: descriptor
 logical                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(nbodyOperatorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nbodyOperatorClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (nbodyOperatorClass)                          , intent(inout) :: self
 type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*             )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(nbodyOperatorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(nbodyOperatorClass), intent(inout) :: self
 class(nbodyOperatorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nbodyOperatorClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`nbodyOperatorNull` A null N-body data operator.

`nbodyOperatorEnvironmentalOverdensity` An N-body data operator which determines the environmental overoverdensity around particles.

`nbodyOperatorMeanPosition` An N-body data operator which determines the mean position and velocity of particles.

`nbodyOperatorRotationCurve` An N-body data operator which computes the rotation curve at a set of given radii.

`nbodyOperatorSequence` An N-body data operator which applies a sequence of other operators.

`nbodyOperatorSelfBound` An N-body data operator which determines the subset of particles that are self-bound.

`nbodyOperatorPairCounts` An N-body data operator which computes pair counts in bins of separation.

`nbodyOperatorVelocityDispersion` An N-body data operator which computes the rotation curve at a set of given radii.

Output Analysis Property Extractor

Additional implementations for output analysis property extractor are added using the `nodePropertyExtractor` class. The implementation should be placed in a file containing the directive:

```
!# <nodePropertyExtractor name="nodePropertyExtractorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </nodePropertyExtractor>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `nodePropertyExtractorMyImplementation`. The file *must* define a type that extends the `nodePropertyExtractorClass` class (or extends another type which is itself an extension of the `nodePropertyExtractorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (nodePropertyExtractorClass), intent(inout)           :: self
 logical                            , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (nodePropertyExtractorClass), intent(inout)           :: self
 type   (inputParameters           ), intent(inout)           :: descriptor
 logical                            , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(nodePropertyExtractorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`addInstances` Add multiple instances of this property to a `multiCounter` object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAddInstances(self,node,instance)
 class(nodePropertyExtractorClass), intent(inout) :: self
 type (treeNode                  ), intent(inout) :: node
 type (multiCounter              ), intent(inout) :: instance
end subroutine myImplementationAddInstances
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nodePropertyExtractorClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`quantity` Return the class of the extracted property. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationQuantity(self)
 class(nodePropertyExtractorClass), intent(inout) :: self
end integer function myImplementationQuantity
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (nodePropertyExtractorClass)                          , intent(inout) :: &
&  self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                     )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(nodePropertyExtractorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(nodePropertyExtractorClass), intent(inout) :: self
 class(nodePropertyExtractorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`type` Return the type of the extracted property. Must have the following interface:

```
integer function myImplementationType(self)
 class(nodePropertyExtractorClass), intent(inout) :: self
end integer function myImplementationType
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (nodePropertyExtractorClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`nodePropertyExtractorVirialProperties` A property extractor class for virial radius and velocity.

`nodePropertyExtractorMassHalo` A halo mass output analysis property extractor class.

`nodePropertyExtractorDescendents` An ISM mass output analysis property extractor class.

`nodePropertyExtractorMassProfile` A property extractor class for the mass enclosed by a set of radii.

`nodePropertyExtractorSatelliteOrbitalExtrema` A satellite orbital extrema luminosity property extractor class.

`nodePropertyExtractorDensityContrasts` A property extractor class for the mass and radii of spheres are specified density contrast.

`nodePropertyExtractorSpinBullock` A node property extractor class for the Bullock et al. [2001] definition of spin parameter.

`nodePropertyExtractorRotationCurve` A property extractor class for the rotation curve at a set of radii.

`nodePropertyExtractorRadiusCooling` A cooling radius property extractor class.

`nodePropertyExtractorIndicesHost` An ISM mass output analysis property extractor class.

`nodePropertyExtractorHaloBias` A node property extractor class for halo bias.

`nodePropertyExtractorICMSZ` An intracluster medium Sunyaev-Zeldovich property extractor class.

`nodePropertyExtractorMassStellar` A stellar mass output analysis property extractor class.

`nodePropertyExtractorMainBranchStatus` An ISM mass output analysis property extractor class.

`nodePropertyExtractorNodeIndices` A property extractor class for basic node indices.

`nodePropertyExtractorNull` A null output analysis property extractor class.

`nodePropertyExtractorRatio` A ratio output analysis property extractor class.

`nodePropertyExtractorMassISM` An ISM mass output analysis property extractor class.

`nodePropertyExtractorIntegerTuple` An abstract output analysis property extractor class which provides a tuple of integer properties.

`nodePropertyExtractorScalar` An abstract output analysis property extractor class which provieds a scalar floating point property.

`nodePropertyExtractorRadiusHalfMass` A radiusHalfMass property extractor class.

`nodePropertyExtractorMassBlackHole` An ISM mass output analysis property extractor class.

`nodePropertyExtractorIntegerScalar` An abstract output analysis property extractor class which provieds a scalar integer property.

`nodePropertyExtractorLmnstyStllrCF2000` A stellar luminosity output analysis property extractor class which applies the dust model of Charlot and Fall [2000].

`nodePropertyExtractorVelocityMaximum` A cooling rate property extractor class.

`nodePropertyExtractorMetallicityISM` An ISM metallicity output analysis property extractor class.

`nodePropertyExtractorMassStellarSpheroid` A spheroid stellar mass output analysis property extractor class.

`nodePropertyExtractorRadiiHalfLightProperties` A half-light radii property extractor class.

`nodePropertyExtractorConcentration` A concentration output analysis property extractor class.

`nodePropertyExtractorProjectedDensity` A property extractor class for the projected density at a set of radii.

`nodePropertyExtractorMostMassiveProgenitor` An ISM mass output analysis property extractor class.

`nodePropertyExtractorFinalDescendent` An ISM mass output analysis property extractor class.

`nodePropertyExtractorSatelliteStatus` An ISM mass output analysis property extractor class.

`nodePropertyExtractorHalfMassRadius` A half-(stellar) mass output analysis property extractor class.

`nodePropertyExtractorMassStellarMorphology` A stellar mass-weighted morphology output analysis property extractor class.

`nodePropertyExtractorTreeWeight` A merger tree weight property extractor class.

`nodePropertyExtractorSpin` A spin parameter output analysis property extractor class.

`nodePropertyExtractorRedshiftLastIsolated` A redshiftLastIsolated property extractor class.

`nodePropertyExtractorDensityProfile` A property extractor class for the density at a set of radii.

`nodePropertyExtractorMulti` A multi output extractor property extractor class.

`nodePropertyExtractorLightcone` A lightcone output extractor property extractor class.

`nodePropertyExtractorIndicesTree` An ISM mass output analysis property extractor class.

`nodePropertyExtractorMassHost` A host halo mass property extractor class.

`nodePropertyExtractorHaloEnvironment` A node property extractor class for halo environment.

`nodePropertyExtractorRateCooling` A cooling rate property extractor class.

`nodePropertyExtractorFractionAccretionHotMode` A hot mode accretion fraction property extractor class.

`nodePropertyExtractorICMXRayLuminosity` An intracluster medium X-ray luminosity property extractor class.

`nodePropertyExtractorLmnstyEmssnLine` A stellar luminosity output analysis property extractor class.

`nodePropertyExtractorLuminosityStellar` A stellar luminosity output analysis property extractor class.

`nodePropertyExtractorVelocityDispersion` A property extractor class for the velocity dispersion at a set of radii.

`nodePropertyExtractorTuple` An abstract output analysis property extractor class which provieds a tuple of floating point properties.

`nodePropertyExtractorRateInfallColdMode` A cold mode infall rate property extractor class.

Unary Operators

Additional implementations for unary operators are added using the `operatorUnary` class. The implementation should be placed in a file containing the directive:

```
!# <operatorUnary name="operatorUnaryMyImplementation">
!# <description>A short description of the implementation.</description>
!# </operatorUnary>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `operator-UnaryMyImplementation`. The file *must* define a type that extends the `operatorUnaryClass` class (or extends another type which is itself an extension of the `operatorUnaryClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`operate` Operate on the given value. Must have the following interface:

```
double precision function myImplementationOperate(self,x)
 class           (operatorUnaryClass), intent(inout) :: self
 double precision                    , intent(in   ) :: x
end double precision function myImplementationOperate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (operatorUnaryClass), intent(inout)           :: self
 logical                    , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (operatorUnaryClass), intent(inout)           :: self
 type   (inputParameters   ), intent(inout)           :: descriptor
 logical                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(operatorUnaryClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (operatorUnaryClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (operatorUnaryClass)                          , intent(inout) :: self
 type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*             )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(operatorUnaryClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(operatorUnaryClass), intent(inout) :: self
 class(operatorUnaryClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`unoperate` Reverse the operation. Must have the following interface:

```
double precision function myImplementationUnoperate(self,f)
 class           (operatorUnaryClass), intent(inout) :: self
 double precision                    , intent(in   ) :: f
end double precision function myImplementationUnoperate
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (operatorUnaryClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`operatorUnaryInverse` An inverse unary operator.

`operatorUnaryIdentity` An identity unary operator.

`operatorUnaryLogarithm` A logarithm unary operator.

Output Analysis

Additional implementations for output analysis are added using the `outputAnalysis` class. The implementation should be placed in a file containing the directive:

```
!# <outputAnalysis name="outputAnalysisMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputAnalysis>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputAnalysisMyImplementation`. The file *must* define a type that extends the `outputAnalysisClass` class (or extends another type which is itself an extension of the `outputAnalysisClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (outputAnalysisClass), intent(inout)           :: self
 logical                     , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (outputAnalysisClass), intent(inout)           :: self
 type   (inputParameters    ), intent(inout)           :: descriptor
 logical                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(outputAnalysisClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (outputAnalysisClass)                          , intent(inout) :: self
 type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*              )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`analyze` Analyze the given `node`. Must have the following interface:

```
subroutine myImplementationAnalyze(self,node,iOutput)
 class  (outputAnalysisClass), intent(inout) :: self
 type   (treeNode           ), intent(inout) :: node
 integer(c_size_t           ), intent(in   ) :: iOutput
end subroutine myImplementationAnalyze
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputAnalysisClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputAnalysisClass), intent(inout) :: self
 class(outputAnalysisClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`logLikelihood` Return the log-likelihood of the analysis. Must have the following interface:

```
double precision function myImplementationLogLikelihood(self)
 class(outputAnalysisClass), intent(inout) :: self
end double precision function myImplementationLogLikelihood
```

`reduce` Reduce the object onto another object of the class. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationReduce(self,reduced)
 class(outputAnalysisClass), intent(inout) :: self
 class(outputAnalysisClass), intent(inout) :: reduced
end subroutine myImplementationReduce
```

`finalize` Finalize the analysis. Must have the following interface:

```
subroutine myImplementationFinalize(self)
 class(outputAnalysisClass), intent(inout) :: self
end subroutine myImplementationFinalize
```

Existing implementations are:

`outputAnalysisMassFunctionStellarBernardi2013SDSS` A Bernardi et al. [2013] stellar mass function output analysis class.

`outputAnalysisMassFunctionHIALFALFAMartin2010` An ALFALFA HI mass function output analysis class.

`outputAnalysisMassFunctionStellarBaldry2012GAMA` A Baldry et al. [2012] stellar mass function output analysis class.

`outputAnalysisLocalGroupMassFunction` An output analysis class for Local Group satellite galaxy mass functions.

`outputAnalysisMassFunctionStellarVIPERS` A VIPERS stellar mass function output analysis class.

`outputAnalysisHIVsHaloMassRelationPadmanabhan2017` An HI vs halo mass relation output analysis class.

`outputAnalysisVolumeFunction1D` A generic 1D volume function (i.e. number density of objects binned by some property, e.g. a mass function) output analysis class.

`outputAnalysisConcentrationVsHaloMassCDMLudlow2016` A concentration vs. halo mass analysis class matched to the Ludlow et al. [2016] CDM sample..

`outputAnalysisMeanFunction1D` A generic 1D mean function (i.e. mean value of some property weighted by number density of objects binned by some property) output analysis class.

`outputAnalysisMassFunctionStellar` A stellar mass function output analysis class.

`outputAnalysisColorDistributionSDSS` An SDSS color distribution function output analysis class.

`outputAnalysisConcentrationDistributionCDMCOCO` A concentration distribution function output analysis class for COCO CDM data.

`outputAnalysisLuminosityFunctionSobral2013HiZELS` An SDSS Hα luminosity function output analysis class for the Sobral et al. [2013] analysis.

`outputAnalysisLuminosityFunctionMonteroDorta2009SDSS` An SDSS luminosity function output analysis class for the Montero-Dorta and Prada [2009] analysis.

`outputAnalysisMassFunctionStellarULTRAVISTA` An ULTRAVISTA stellar mass function output analysis class.

`outputAnalysisLuminosityFunctionHalpha` A luminosity function output analysis class.

`outputAnalysisMorphologicalFractionGAMAMoffett2016` A morphological fraction output analysis class for the analysis of Moffett et al. [2016].

`outputAnalysisCorrelationFunctionHearin2013SDSS` A correlation function output analysis class for the Hearin et al. [2013] analysis.

`outputAnalysisCorrelationFunction` A generic two-point correlation function output analysis class.

`outputAnalysisSpinDistributionBett2007` A stellar mass function output analysis class.

`outputAnalysisMassFunctionStellarPRIMUS` A PRIMUS stellar mass function output analysis class.

`outputAnalysisMassFunctionStellarUKIDSSUDS` A UKIDSS UDS stellar mass function output analysis class.

`outputAnalysisMassMetallicityAndrews2013` A mass-metallicity relation output analysis class.

`outputAnalysisScatterFunction1D` A generic 1D scatter function (i.e. the scatter of some property weighted by number density of objects binned by some property) output analysis class.

`outputAnalysisLuminosityFunction` A luminosity function output analysis class.

`outputAnalysisNull` A null output analysis class.

`outputAnalysisMassMetallicityBlanc2017` A mass-metallicity relation output analysis class.

`outputAnalysisStellarVsHaloMassRelationLeauthaud2012` A stellar vs halo mass relation output analysis class.

`outputAnalysisLuminosityFunctionGunawardhana2013SDSS` An SDSS Hα luminosity function output analysis class for the Gunawardhana et al. [2013] analysis.

`outputAnalysisMassFunctionHI` An HI mass function output analysis class.

`outputAnalysisMassFunctionStellarZFOURGE` A ZFOURGE stellar mass function output analysis class.

`outputAnalysisGalaxySizesSDSS` A stellar mass function output analysis class.

`outputAnalysisBlackHoleBulgeRelation` A mass-metallicity relation output analysis class.

`outputAnalysisMassFunctionStellarSDSS` An SDSS stellar mass function output analysis class.

`outputAnalysisMulti` A merger tree analysis class which combines multiple other analyses.

Output Analysis Distribution Normalizer

Additional implementations for output analysis distribution normalizer are added using the `outputAnalysisDistributionNor` class. The implementation should be placed in a file containing the directive:

```
!# <outputAnalysisDistributionNormalizer name="outputAnalysisDistributionNormalizerMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputAnalysisDistributionNormalizer>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputAnalysisDistributionNormalizerMyImplementation`. The file *must* define a type that extends the `outputAnalysisDistributionNormalizerClass` class (or extends another type which is itself an extension of the `outputAnalysisDistributionNormalizerClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (outputAnalysisDistributionNormalizerClass), intent(inout)          :: self
  logical                                           , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (outputAnalysisDistributionNormalizerClass), intent(inout)          :: self
  type   (inputParameters                          ), intent(inout)          :: &
&  descriptor
  logical                                           , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(outputAnalysisDistributionNormalizerClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (outputAnalysisDistributionNormalizerClass), intent(inout) :: self
  integer                                           , intent(in   ) :: stateFile
  type   (fgsl_file                                 ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                  ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (outputAnalysisDistributionNormalizerClass)                          , &
&  intent(inout) :: self
  type     (varying_string                            ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
  character(len=*                                     )                          , &
&  intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`normalize` Normalize a distribution. Must have the following interface:

```
 subroutine myImplementationNormalize(self,distribution,covariance,propertyValueMinimum,&
&   propertyValueMaximum)
  class           (outputAnalysisDistributionNormalizerClass)               , intent(&
&  inout) :: self
  double precision                                          , dimension(:)  , intent(&
&  inout) :: distribution
```

```
  double precision                                          , dimension(:,:), intent(&
&  inout) :: covariance
  double precision                                          , dimension(:)  , intent(in&
&     ) :: propertyValueMinimum, propertyValueMaximum
 end subroutine myImplementationNormalize
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputAnalysisDistributionNormalizerClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputAnalysisDistributionNormalizerClass), intent(inout) :: self
 class(outputAnalysisDistributionNormalizerClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisDistributionNormalizerClass), intent(inout) :: self
 integer                                           , intent(in   ) :: stateFile
 type   (fgsl_file                                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`outputAnalysisDistributionNormalizerSequence` Provides a sequence of normalizers on on-the-fly outputs.

`outputAnalysisDistributionNormalizerIdentity` An identity output analysis distribution normalizer class.

`outputAnalysisDistributionNormalizerBinWidth` A bin width output analysis distribution normalizer class.

`outputAnalysisDistributionNormalizerUnitarity` A unitarity output analysis distribution normalizer class.

`outputAnalysisDistributionNormalizerLog10ToLog` A $\log_{10} \rightarrow$ log output analysis distribution normalizer class.

Output Analysis Distribution Operator

Additional implementations for output analysis distribution operator are added using the `outputAnalysisDistributionOpera` class. The implementation should be placed in a file containing the directive:

```
!# <outputAnalysisDistributionOperator name="outputAnalysisDistributionOperatorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputAnalysisDistributionOperator>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputAnalysisDistributionOperatorMyImplementation`. The file *must* define a type that extends the `outputAnalysisDistributionOperatorClass` class (or extends another type which is itself an extension of the `outputAnalysisDistributionOperatorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (outputAnalysisDistributionOperatorClass), intent(inout)           :: self
  logical                                         , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (outputAnalysisDistributionOperatorClass), intent(inout)           :: self
  type   (inputParameters                        ), intent(inout)           :: &
&  descriptor
  logical                                         , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(outputAnalysisDistributionOperatorClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (outputAnalysisDistributionOperatorClass), intent(inout) :: self
  integer                                         , intent(in   ) :: stateFile
  type   (fgsl_file                               ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (outputAnalysisDistributionOperatorClass)                          , intent(&
&  inout) :: self
```

```
  type     (varying_string                          ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                                   )                           , intent(&
&  in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`operateScalar` Operate on a scalar to produce a distribution. Must have the following interface:

```
 double precision, dimension(size(propertyValueMinimum)) function &
&  myImplementationOperateScalar(self,propertyValue,propertyType,propertyValueMinimum, &
&  propertyValueMaximum,outputIndex,node)
  class           (outputAnalysisDistributionOperatorClass)              , intent(inout)&
&   :: self
  double precision                                                       , intent(in   )&
&   :: propertyValue
  integer                                                                , intent(in   )&
&   :: propertyType
  double precision                                          , dimension(:), intent(in   )&
&   :: propertyValueMinimum, propertyValueMaximum
  integer         (c_size_t                                )             , intent(in   )&
&   :: outputIndex
  type            (treeNode                                )             , intent(inout)&
&   :: node
 end double precision, dimension(size(propertyValueMinimum)) function &
&  myImplementationOperateScalar
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputAnalysisDistributionOperatorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputAnalysisDistributionOperatorClass), intent(inout) :: self
 class(outputAnalysisDistributionOperatorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisDistributionOperatorClass), intent(inout) :: self
 integer                                         , intent(in   ) :: stateFile
 type   (fgsl_file                               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`operateDistribution` Operate on a distribution to produce a distribution. Must have the following interface:

```
 double precision, dimension(size(propertyValueMinimum)) function &
&  myImplementationOperateDistribution(self,distribution,propertyType,&
&  propertyValueMinimum, propertyValueMaximum,outputIndex,node)
  class           (outputAnalysisDistributionOperatorClass)             , intent(inout)&
&   :: self
  double precision                                                , dimension(:), intent(in   )&
&   :: distribution
  integer                                                                       , intent(in   )&
&   :: propertyType
  double precision                                                , dimension(:), intent(in   )&
&   :: propertyValueMinimum, propertyValueMaximum
  integer         (c_size_t                                      )              , intent(in   )&
&   :: outputIndex
  type            (treeNode                                      )              , intent(inout)&
&   :: node
 end double precision, dimension(size(propertyValueMinimum)) function &
&  myImplementationOperateDistribution
```

Existing implementations are:

`outputAnalysisDistributionOperatorRndmErrNbodyMass` A random error output analysis distribution operator class providing errors in $\log_{10}$ of N-body halo mass.

`outputAnalysisDistributionOperatorIdentity` A identity output analysis distribution operator class.

`outputAnalysisDistributionOperatorGrvtnlLnsng` A gravitational lensing output analysis distribution operator class.

`outputAnalysisDistributionOperatorRandomErrorALFLF` A random error output analysis distribution operator class providing errors in HI mass for the ALFALFA survey. Specifically, $\sigma_{\rm obs} = a + \exp\left(-\frac{\log_{10}(M_{\rm HI}/M_\odot)-b}{c}\right)$.

`outputAnalysisDistributionOperatorRandomErrorFixed` A random error output analysis distribution operator class.

`outputAnalysisDistributionOperatorRandomErrorPlynml` A random error output analysis distribution operator class.

`outputAnalysisDistributionOperatorSpinNBodyErrors` An output analysis distribution operator class to account for errors on N-body measurements of halo spin.

`outputAnalysisDistributionOperatorSequence` A sequence output analysis distribution operator class.

`outputAnalysisDistributionOperatorRandomError` A random error output analysis distribution operator class.

`outputAnalysisDistributionOperatorRndmErrNbdyCnc` A random error output analysis distribution operator class providing errors in $\log_{10}$ of N-body halo concentration.

`outputAnalysisDistributionOperatorDiskSizeInclntn` An output analysis distribution operator class which implements the effects of inclination on disk size.

Output Analysis Molecular Ratio

Additional implementations for output analysis molecular ratio are added using the `outputAnalysisMolecularRatio` class. The implementation should be placed in a file containing the directive:

```
!# <outputAnalysisMolecularRatio name="outputAnalysisMolecularRatioMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputAnalysisMolecularRatio>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputAnalysisMolecularRatioMyImplementation`. The file *must* define a type that extends the `outputAnalysisMolecularRatioClass` class (or extends another type which is itself an extension of the `outputAnalysisMolecularRatioClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`ratio` Return the molecular ratio, $R_{\rm mol} = M_{\rm H_2}/M_{\rm HI}$. Must have the following interface:

```
double precision function myImplementationRatio(self,massISM,node)
 class           (outputAnalysisMolecularRatioClass), intent(inout) :: self
 double precision                                   , intent(in   ) :: massISM
 type            (treeNode                         ), intent(inout) :: node
end double precision function myImplementationRatio
```

`ratioScatter` Return the scatter in logarithmic molecular ratio, $\log_{10} R_{\rm mol} = \log_{10}(M_{\rm H_2}/M_{\rm HI})$. Must have the following interface:

```
double precision function myImplementationRatioScatter(self,massISM,node)
 class           (outputAnalysisMolecularRatioClass), intent(inout) :: self
 double precision                                   , intent(in   ) :: massISM
 type            (treeNode                         ), intent(inout) :: node
end double precision function myImplementationRatioScatter
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (outputAnalysisMolecularRatioClass), intent(inout)          :: self
  logical                                   , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (outputAnalysisMolecularRatioClass), intent(inout)          :: self
 type   (inputParameters                  ), intent(inout)          :: descriptor
 logical                                   , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(outputAnalysisMolecularRatioClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisMolecularRatioClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (outputAnalysisMolecularRatioClass)                          , intent(inout)&
&   :: self
 type     (varying_string                   ), allocatable, dimension(:), intent(inout)&
&   :: allowedParameters
 character(len=*                            )                          , intent(in   )&
&   :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputAnalysisMolecularRatioClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputAnalysisMolecularRatioClass), intent(inout) :: self
 class(outputAnalysisMolecularRatioClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisMolecularRatioClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`outputAnalysisMolecularRatioObreschkow2009` A high-pass filter analysis property operator class.

Output Analysis Property Operator

Additional implementations for output analysis property operator are added using the `outputAnalysisPropertyOperator` class. The implementation should be placed in a file containing the directive:

```
!# <outputAnalysisPropertyOperator name="outputAnalysisPropertyOperatorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputAnalysisPropertyOperator>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputAnalysisPropertyOperatorMyImplementation`. The file *must* define a type that extends the `outputAnalysisPropertyOperatorClass` class (or extends another type which is itself an extension of the `outputAnalysisPropertyOperatorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`operate` Operate on the given property. Must have the following interface:

```
 double precision function myImplementationOperate(self,propertyValue,node,propertyType,&
&  outputIndex)
  class           (outputAnalysisPropertyOperatorClass), intent(inout)           :: self
  double precision                                     , intent(in   )           :: &
&  propertyValue
  type            (treeNode                           ), intent(inout), optional :: node
  integer                                              , intent(inout), optional :: &
&  propertyType
  integer         (c_size_t                           ), intent(in   ), optional :: &
&  outputIndex
 end double precision function myImplementationOperate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (outputAnalysisPropertyOperatorClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (outputAnalysisPropertyOperatorClass), intent(inout)           :: self
 type   (inputParameters                     ), intent(inout)           :: descriptor
 logical                                      , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(outputAnalysisPropertyOperatorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisPropertyOperatorClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (outputAnalysisPropertyOperatorClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputAnalysisPropertyOperatorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputAnalysisPropertyOperatorClass), intent(inout) :: self
 class(outputAnalysisPropertyOperatorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisPropertyOperatorClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`outputAnalysisPropertyOperatorAntiLog10` An anti-$\log_{10}()$ output analysis property operator class.

`outputAnalysisPropertyOperatorLog10` An log10 output analysis property operator class.

`outputAnalysisPropertyOperatorSystmtcPolynomial` A polynomial systematic shift output analysis property operator class.

`outputAnalysisPropertyOperatorCsmlgyAnglrDstnc` A cosmological angular distance corrector analysis property operator class.

`outputAnalysisPropertyOperatorMultiply` A high-pass filter analysis property operator class.

`outputAnalysisPropertyOperatorCsmlgyLmnstyDstnc` A cosmological luminosity distance corrector analysis property operator class.

`outputAnalysisPropertyOperatorMagnitude` An output analysis property operator class.

`outputAnalysisPropertyOperatorNormal` A property operator class in which the property value is replaced with an integral over a normal distribution between given limits, using the property value at the mean of the distribution.

`outputAnalysisPropertyOperatorBoolean` A boolean analysis property operator class, specifically $x \rightarrow x/|x|$, that is, the operator maintains the sign of the input while normalizing the magnitude to unity (or zero for zero input).

`outputAnalysisPropertyOperatorSequence` A sequence output analysis property operator class.

`outputAnalysisPropertyOperatorIdentity` An identity output analysis property operator class.

`outputAnalysisPropertyOperatorSquare` An square output analysis property operator class.

`outputAnalysisPropertyOperatorFilterHighPass` A high-pass filter analysis property operator class.

`outputAnalysisPropertyOperatorMetallicity12LogNH` A property operator class which converts a metallicity, assumed to be a mass ratio of a given element to hydrogen, to $12 + \log_{10}(\mathrm{N/H})$ form.

`outputAnalysisPropertyOperatorSquareRoot` An squareRoot output analysis property operator class.

`outputAnalysisPropertyOperatorHIMass` A conversion of ISM mass to HI mass analysis property operator class.

`outputAnalysisPropertyOperatorMinMax` A min-max analysis property operator class.

Output Analysis Weight Operator

Additional implementations for output analysis weight operator are added using the `outputAnalysisWeightOperator` class. The implementation should be placed in a file containing the directive:

```
!# <outputAnalysisWeightOperator name="outputAnalysisWeightOperatorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputAnalysisWeightOperator>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputAnalysisWeightOperatorMyImplementation`. The file *must* define a type that extends the `outputAnalysisWeightOperatorClass` class (or extends another type which is itself an extension of the `outputAnalysisWeightOperatorClass`

class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`operate` Operate on the given weight. Must have the following interface:

```
 double precision function myImplementationOperate(self,weightValue,node,propertyValue, &
&  propertyValueIntrinsic,propertyType , propertyQuantity,outputIndex)
  class           (outputAnalysisWeightOperatorClass), intent(inout) :: self
  double precision                                   , intent(in   ) :: weightValue
  type            (treeNode                         ), intent(inout) :: node
  double precision                                   , intent(in   ) :: propertyValue, &
&  propertyValueIntrinsic
  integer                                            , intent(in   ) :: propertyType, &
&  propertyQuantity
  integer         (c_size_t                         ), intent(in   ) :: outputIndex
 end double precision function myImplementationOperate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (outputAnalysisWeightOperatorClass), intent(inout)           :: self
  logical                                   , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (outputAnalysisWeightOperatorClass), intent(inout)           :: self
 type   (inputParameters                  ), intent(inout)           :: descriptor
 logical                                   , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(outputAnalysisWeightOperatorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisWeightOperatorClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (outputAnalysisWeightOperatorClass)                          , intent(inout)&
&   :: self
 type     (varying_string                  ), allocatable, dimension(:), intent(inout)&
&   :: allowedParameters
 character(len=*                           )                          , intent(in   )&
&   :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputAnalysisWeightOperatorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputAnalysisWeightOperatorClass), intent(inout) :: self
 class(outputAnalysisWeightOperatorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputAnalysisWeightOperatorClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`outputAnalysisWeightOperatorFilterHighPass` A high-pass filter analysis weight operator class.

`outputAnalysisWeightOperatorProperty` An analysis weight operator class which weights by a property value.

`outputAnalysisWeightOperatorNormal` A weight operator class in which the weight is multiplied by an integral over a normal distribution.

`outputAnalysisWeightOperatorNbodyMass` A weight operator class in which the weight is multiplied by an integral over the N-body halo mass distribution.

`outputAnalysisWeightOperatorSequence` A sequence output analysis weight operator class.

`outputAnalysisWeightOperatorIdentity` An identity analysis weight operator class.

`outputAnalysisWeightOperatorCsmlgyVolume` A cosmological volume corrector analysis weight operator class.

Output Times

Additional implementations for output times are added using the `outputTimes` class. The implementation should be placed in a file containing the directive:

```
!# <outputTimes name="outputTimesMyImplementation">
!# <description>A short description of the implementation.</description>
!# </outputTimes>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `outputTimesMyImplementation`. The file *must* define a type that extends the `outputTimesClass` class (or extends another type which is itself an extension of the `outputTimesClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`timeNext` Given a `time`, return the time of the next output, and (optionally) the index of that output. Must have the following interface:

```
double precision function myImplementationTimeNext(self,timeCurrent,indexOutput)
 class           (outputTimesClass), intent(inout)           :: self
 double precision                  , intent(in   )           :: timeCurrent
 integer         (c_size_t        ), intent(  out), optional :: indexOutput
end double precision function myImplementationTimeNext
```

`count` Return the number of output times. Must have the following interface:

```
integer(c_size_t) function myImplementationCount(self)
 class(outputTimesClass), intent(inout) :: self
end integer(c_size_t) function myImplementationCount
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (outputTimesClass), intent(inout)           :: self
 logical                  , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (outputTimesClass), intent(inout)           :: self
 type   (inputParameters ), intent(inout)           :: descriptor
 logical                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(outputTimesClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`time` Return the output time index by `indexOutput`. Must have the following interface:

```
double precision function myImplementationTime(self,indexOutput)
 class  (outputTimesClass), intent(inout) :: self
 integer(c_size_t        ), intent(in   ) :: indexOutput
end double precision function myImplementationTime
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputTimesClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (outputTimesClass)                          , intent(inout) :: self
 type     (varying_string  ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*           )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`index` Return the index of the output at the given `time`. If `findClosest` is given and is true then the closest matching output is returned. Must have the following interface:

```
integer(c_size_t) function myImplementationIndex(self,time,findClosest)
 class           (outputTimesClass), intent(inout)           :: self
 double precision                  , intent(in   )           :: time
 logical                           , intent(in   ), optional :: findClosest
end integer(c_size_t) function myImplementationIndex
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(outputTimesClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`redshift` Return the output redshift index by `indexOutput`. Must have the following interface:

```
double precision function myImplementationRedshift(self,indexOutput)
 class  (outputTimesClass), intent(inout) :: self
 integer(c_size_t        ), intent(in   ) :: indexOutput
end double precision function myImplementationRedshift
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(outputTimesClass), intent(inout) :: self
 class(outputTimesClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (outputTimesClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`timePrevious` Given a `time`, return the time of the previous output. Must have the following interface:

```
double precision function myImplementationTimePrevious(self,timeCurrent)
 class           (outputTimesClass), intent(inout) :: self
 double precision                  , intent(in   ) :: timeCurrent
end double precision function myImplementationTimePrevious
```

Existing implementations are:

`outputTimesList` An output times class which simply reads a list of output times from a parameter.

Posterior Sampling Convergence Criteria

Additional implementations for posterior sampling convergence criteria are added using the `posteriorSampleConvergence` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleConvergence name="posteriorSampleConvergenceMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleConvergence>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleConvergenceMyImplementation`. The file *must* define a type that extends the `posteriorSampleConvergenceClass` class (or extends another type which is itself an extension of the `posteriorSampleConvergenceClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`logReport` Log a report on convergence state to the given file unit. Must have the following interface:

```
subroutine myImplementationLogReport(self,fileUnit)
 class  (posteriorSampleConvergenceClass), intent(inout) :: self
 integer                                 , intent(in   ) :: fileUnit
end subroutine myImplementationLogReport
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (posteriorSampleConvergenceClass), intent(inout)          :: self
  logical                                 , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (posteriorSampleConvergenceClass), intent(inout)          :: self
 type   (inputParameters                ), intent(inout)          :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(posteriorSampleConvergenceClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleConvergenceClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleConvergenceClass)                          , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`stateIsOutlier` Return true if the specified state is deemed to be an outlier. Must have the following interface:

```
logical function myImplementationStateIsOutlier(self,stateIndex)
 class  (posteriorSampleConvergenceClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateIndex
end logical function myImplementationStateIsOutlier
```

`reset` Reset the convergence calculation. Must have the following interface:

```
subroutine myImplementationReset(self)
 class(posteriorSampleConvergenceClass), intent(inout) :: self
end subroutine myImplementationReset
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleConvergenceClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleConvergenceClass), intent(inout) :: self
 class(posteriorSampleConvergenceClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`isConverged` Returns true if the posterior sampling is deemed to be converged. Must have the following interface:

```
logical function myImplementationIsConverged(self,simulationState,logLikelihood)
 class           (posteriorSampleConvergenceClass), intent(inout)           :: self
 class           (posteriorSampleStateClass      ), intent(inout), optional :: &
&  simulationState
 double precision                                 , intent(in   ), optional :: &
&  logLikelihood
 end logical function myImplementationIsConverged
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleConvergenceClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`convergedAtStep` Returns the step at which the sampling reached convergence. Must have the following interface:

```
integer function myImplementationConvergedAtStep(self)
 class(posteriorSampleConvergenceClass), intent(inout) :: self
end integer function myImplementationConvergedAtStep
```

Existing implementations are:

`posteriorSampleConvergenceGelmanRubin` A posterior sampling convergence class which implements the Gelman-Rubin statistic.

`posteriorSampleConvergenceNever` A posterior sampling convergence class which never converges.

`posteriorSampleConvergenceLikelihoodThreshold` A posterior sampling convergence class which declares convergence once all likelihoods are above a threshold.

Posterior Sampling Differential Evolution Proposal Size

Additional implementations for posterior sampling differential evolution proposal size are added using the `posteriorSampleDffrntlEvltnProposalSize` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleDffrntlEvltnProposalSize name="posteriorSampleDffrntlEvltnProposalSizeMyImplementatio
!# <description>A short description of the implementation.</description>
!# </posteriorSampleDffrntlEvltnProposalSize>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleDffrntlEvltnProposalSizeMyImplementation`. The file *must* define a type that extends the `posteriorSampleDffrntlEvltnProposalSizeClass` class (or extends another type which is itself an extension of the `posteriorSampleDffrntlEvltnProposalSizeClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout)          :: self
  logical                                              , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout)          :: self
  type   (inputParameters                              ), intent(inout)          :: &
&  descriptor
  logical                                              , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: self
```

```
 integer                                                , intent(in   ) :: stateFile
 type   (fgsl_file                                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                      ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (posteriorSampleDffrntlEvltnProposalSizeClass)                         , &
&  intent(inout) :: self
  type     (varying_string                               ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
  character(len=*                                        )                         , &
&  intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`gamma` Sample from the jump distribution. Must have the following interface:

```
 double precision function myImplementationGamma(self,simulationState,&
&  simulationConvergence)
  class(posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: self
  class(posteriorSampleStateClass                   ), intent(inout) :: simulationState
  class(posteriorSampleConvergenceClass             ), intent(inout) :: &
&  simulationConvergence
 end double precision function myImplementationGamma
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: self
  class(posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
  class  (posteriorSampleDffrntlEvltnProposalSizeClass), intent(inout) :: self
  integer                                               , intent(in   ) :: stateFile
  type   (fgsl_file                                     ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                      ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleDffrntlEvltnProposalSizeFixed` A posterior sampling differential evolution proposal size class in which the proposal size is fixed.

`posteriorSampleDffrntlEvltnProposalSizeAdaptive` A posterior sampling differential evolution proposal size class in which the proposal size is adaptive.

Posterior Sampling Differential Evolution Proposal Size Temperature Exponent

Additional implementations for posterior sampling differential evolution proposal size temperature exponent are added using the `posteriorSampleDffrntlEvltnPrpslSzTmpExp` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleDffrntlEvltnPrpslSzTmpExp name="posteriorSampleDffrntlEvltnPrpslSzTmpExpMyImplementat
!# <description>A short description of the implementation.</description>
!# </posteriorSampleDffrntlEvltnPrpslSzTmpExp>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleDffrntlEvltnPrpslSzTmpExpMyImplementation`. The file *must* define a type that extends the `posteriorSampleDffrntlEvltnPrpslSzTmpExpClass` class (or extends another type which is itself an extension of the `posteriorSampleDffrntlEvltnPrpslSzTmpExpClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&)
  class  (posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout)           :: &
&  self
  logical                                               , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout)           :: &
&  self
  type   (inputParameters                               ), intent(inout)           :: &
&  descriptor
  logical                                               , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout) :: self
 integer                                               , intent(in   ) :: stateFile
 type   (fgsl_file                                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                      ), intent(in   ) :: &
&  stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleDffrntlEvltnPrpslSzTmpExpClass)                          , &
&  intent(inout) :: self
 type     (varying_string                                ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
 character(len=*                                         )                          , &
&  intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout) :: self
 class(posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`exponent` Return the temperature exponent. Must have the following interface:

```
double precision function myImplementationExponent(self,temperedStates,temperatures,&
&  simulationState,simulationConvergence)
 class           (posteriorSampleDffrntlEvltnPrpslSzTmpExpClass)              , intent(&
&  inout) :: self
 class           (posteriorSampleStateClass                   ), dimension(:), intent(&
&  inout) :: temperedStates
 double precision                                               , dimension(:), intent(&
&  in   ) :: temperatures
 class           (posteriorSampleStateClass                   )              , intent(&
&  inout) :: simulationState
```

```
     class           (posteriorSampleConvergenceClass             )              , intent(&
    &  inout) :: simulationConvergence
     end double precision function myImplementationExponent
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
    subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
     class  (posteriorSampleDffrntlEvltnPrpslSzTmpExpClass), intent(inout) :: self
     integer                                               , intent(in   ) :: stateFile
     type   (fgsl_file                                     ), intent(in   ) :: fgslStateFile
     integer(c_size_t                                      ), intent(in   ) :: &
    &  stateOperationID
     end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleDffrntlEvltnPrpslSzTmpExpAdaptive` A posterior sampling differential evolution proposal size class in which the exponent is adaptive.

`posteriorSampleDffrntlEvltnPrpslSzTmpExpFixed` A posterior sampling differential evolution proposal size class in which the exponent is fixed.

Posterior Sampling Differential Evolution Random Jumps

Additional implementations for posterior sampling differential evolution random jumps are added using the `posteriorSampleDffrntlEvltnRandomJump` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleDffrntlEvltnRandomJump name="posteriorSampleDffrntlEvltnRandomJumpMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleDffrntlEvltnRandomJump>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleDffrntlEvltnRandomJumpMyImplementation`. The file *must* define a type that extends the `posteriorSampleDffrntlEvltnRandomJumpClass` class (or extends another type which is itself an extension of the `posteriorSampleDffrntlEvltnRandomJumpClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
    type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
    &  )
     class  (posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout)          :: self
     logical                                            , intent(in   ), optional :: &
    &  includeSourceDigest
     end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout)           :: self
 type   (inputParameters                            ), intent(inout)           :: &
&  descriptor
 logical                                             , intent(in   ), optional :: &
&  includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout) :: self
 integer                                             , intent(in   ) :: stateFile
 type   (fgsl_file                                   ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                    ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleDffrntlEvltnRandomJumpClass)                          , &
&  intent(inout) :: self
 type     (varying_string                            ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
 character(len=*                                     )                          , &
&  intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout) :: self
 class(posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`sample` Sample from the jump distribution. Must have the following interface:

```
 double precision, dimension(size(modelParameters_)) function myImplementationSample(&
&  self,modelParameters_,simulationState)
  class(posteriorSampleDffrntlEvltnRandomJumpClass)              , intent(inout) :: self
  type (modelParameterList                        ), dimension(:), intent(in   ) :: &
&  modelParameters_
  class(posteriorSampleStateClass                 )              , intent(inout) :: &
&  simulationState
 end double precision, dimension(size(modelParameters_)) function myImplementationSample
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
  class  (posteriorSampleDffrntlEvltnRandomJumpClass), intent(inout) :: self
  integer                                            , intent(in   ) :: stateFile
  type   (fgsl_file                                  ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                   ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleDffrntlEvltnRandomJumpSimple` A posterior sampling differential evolution random jump class in which the jump is drawn from a fixed distribution.

`posteriorSampleDffrntlEvltnRandomJumpAdaptive` A posterior sampling differential evolution random jump class in which the jump is drawn from an adaptive distribution which scales with the range spanned by the sample states..

Posterior Sampling Likelihoods

Additional implementations for posterior sampling likelihoods are added using the `posteriorSampleLikelihood` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleLikelihood name="posteriorSampleLikelihoodMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleLikelihood>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleLikelihoodMyImplementation`. The file *must* define a type that extends the `posteriorSampleLikelihoodClass` class (or extends another type which is itself an extension of the `posteriorSampleLikelihoodClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (posteriorSampleLikelihoodClass), intent(inout)          :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (posteriorSampleLikelihoodClass), intent(inout)          :: self
 type   (inputParameters               ), intent(inout)          :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(posteriorSampleLikelihoodClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleLikelihoodClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`evaluate` Evaluate the likelihood. Must have the following interface:

```
 double precision function myImplementationEvaluate(self,simulationState,&
&  modelParametersActive_, modelParametersInactive_,simulationConvergence,temperature, &
&  logLikelihoodCurrent, logPriorCurrent, logPriorProposed,timeEvaluate,&
&  logLikelihoodVariance,forceAcceptance)
  class           (posteriorSampleLikelihoodClass )              , intent(inout)        &
&     :: self
  class           (posteriorSampleStateClass      )              , intent(inout)        &
&     :: simulationState
  type            (modelParameterList             ), dimension(:), intent(in   )        &
&     :: modelParametersActive_, modelParametersInactive_
  class           (posteriorSampleConvergenceClass)              , intent(inout)        &
&     :: simulationConvergence
  double precision                                               , intent(in   )        &
&     :: temperature, logLikelihoodCurrent, logPriorCurrent, logPriorProposed
  real                                                           , intent(inout)        &
&     :: timeEvaluate
  double precision                                               , intent(  out), &
&  optional :: logLikelihoodVariance
  logical                                                        , intent(inout), &
&  optional :: forceAcceptance
 end double precision function myImplementationEvaluate
```

`restore` Log a report on convergence state to the given file unit. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationRestore(self,simulationState,logLikelihood)
 class           (posteriorSampleLikelihoodClass)              , intent(inout) :: self
 double precision                                 , dimension(:), intent(in   ) :: &
&  simulationState
 double precision                                               , intent(in   ) :: &
&  logLikelihood
end subroutine myImplementationRestore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleLikelihoodClass)                          , intent(inout) ::&
&   self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) ::&
&   allowedParameters
 character(len=*                        )                          , intent(in   ) ::&
&   sourceName
end subroutine myImplementationAllowedParameters
```

`functionChanged` Respond to possible changes in the likelihood function. Must have the following interface:

```
subroutine myImplementationFunctionChanged(self)
 class(posteriorSampleLikelihoodClass), intent(inout) :: self
end subroutine myImplementationFunctionChanged
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleLikelihoodClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`willEvaluate` Returns true if the likelihood will be evaluated for this state. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationWillEvaluate(self,simulationState,modelParameters_,&
&  simulationConvergence,temperature, logLikelihoodCurrent, logPriorCurrent, &
&  logPriorProposed)
 class           (posteriorSampleLikelihoodClass )              , intent(inout) :: self
 class           (posteriorSampleStateClass      )              , intent(inout) :: &
&  simulationState
 type            (modelParameterList             ), dimension(:), intent(in   ) :: &
&  modelParameters_
 class           (posteriorSampleConvergenceClass)              , intent(inout) :: &
&  simulationConvergence
 double precision                                               , intent(in   ) :: &
&  temperature, logLikelihoodCurrent, logPriorCurrent, logPriorProposed
end logical function myImplementationWillEvaluate
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleLikelihoodClass), intent(inout) :: self
 class(posteriorSampleLikelihoodClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleLikelihoodClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleLikelihoodMassFunction` A posterior sampling likelihood class which implements a likelihood for mass functions.

`posteriorSampleLikelihoodIndpndntLklhdsSqntl` A posterior sampling likelihood class which sequentially combines other likelihoods assumed to be independent. This class begins by evaluating the first likelihood. If the likelihood is negative, then it is immediately returned, without evaluation of any further likelihoods. If it is positive, then the next likelihood is evaluated and the same conditions applied. This process repeats until either a negative likelihood is found, or all likelihoods are evaluated. Once a given likelihood has been evaluated it will be evaluated on all subsequent calls. Additionally, when a new likelihood is evaluated for the first time, acceptance of the proposed state will be forced. This class therefore allows a sequence of likelihoods to be specified which must be sequentially made sufficiently "good" before evaluating the next. The approach is intended to allow crude, but rapid constraints to be placed on parameters before progressing to more detailed, but slow to evaluate constraints.

`posteriorSampleLikelihoodHaloMassFunction` A posterior sampling likelihood class which implements a likelihood for halo mass functions.

`posteriorSampleLikelihoodPrjctdCorrelationFunction` A posterior sampling likelihood class which implements a likelihood for projected correlation functions.

`posteriorSampleLikelihoodGaussianRegression` A posterior sampling likelihood class which implements a likelihood using Gaussian regression to emulate another likelihood.

`posteriorSampleLikelihoodMltiVrtNormalStochastic` A posterior sampling likelihood class which implements a multivariate normal.

`posteriorSampleLikelihoodPosteriorAsPrior` A posterior sampling likelihood class which implements a likelihood using a given posterior distribution over the parameters in the form of a set of MCMC chains.

`posteriorSampleLikelihoodSEDFit` A posterior sampling likelihood class which implements a likelihood for SED fitting.

`posteriorSampleLikelihoodIndependentLikelihoods` A posterior sampling likelihood class which combines other likelihoods assumed to be independent.

`posteriorSampleLikelihoodSpinDistribution` A posterior sampling likelihood class which implements a likelihood for halo spin distributions.

`posteriorSampleLikelihoodGalaxyPopulation` A posterior sampling likelihood class which implements a likelihood for Galacticus models.

`posteriorSampleLikelihoodMultivariateNormal` A posterior sampling likelihood class which implements a multivariate normal.

Posterior Sampling Simulations

Additional implementations for posterior sampling simulations are added using the `posteriorSampleSimulation` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleSimulation name="posteriorSampleSimulationMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleSimulation>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleSimulationMyImplementation`. The file *must* define a type that extends the `posteriorSampleSimulationClass` class (or extends another type which is itself an extension of the `posteriorSampleSimulationClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (posteriorSampleSimulationClass), intent(inout)          :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (posteriorSampleSimulationClass), intent(inout)          :: self
 type   (inputParameters               ), intent(inout)          :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(posteriorSampleSimulationClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleSimulationClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleSimulationClass)                          , intent(inout) ::&
&  self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) ::&
&  allowedParameters
 character(len=*                         )                          , intent(in   ) ::&
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`simulate` Perform the simulation. Must have the following interface:

```
subroutine myImplementationSimulate(self)
 class(posteriorSampleSimulationClass), intent(inout) :: self
end subroutine myImplementationSimulate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleSimulationClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleSimulationClass), intent(inout) :: self
 class(posteriorSampleSimulationClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleSimulationClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleSimulationAnnealedDffrntlEvltn` A posterior sampling simulation class which implements an annealed differential evolution algorithm.

`posteriorSampleSimulationParticleSwarm` A posterior sampling simulation class which implements the particle swarm algorithm.

`posteriorSampleSimulationStochasticDffrntlEvltn` A posterior sampling simulation class which implements a stochastic differential evolution algorithm.

`posteriorSampleSimulationDifferentialEvolution` A posterior sampling simulation class which implements the differential evolution algorithm.

`posteriorSampleSimulationTemperedDffrntlEvltn` A posterior sampling simulation class which implements a tempered differential evolution algorithm.

Posterior Sampling State

Additional implementations for posterior sampling state are added using the `posteriorSampleState` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleState name="posteriorSampleStateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleState>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleStateMyImplementation`. The file *must* define a type that extends the `posteriorSampleStateClass` class (or extends another type which is itself an extension of the `posteriorSampleStateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`chainIndexSet` Set the index of the chain associated with this state. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationChainIndexSet(self,chainIndex)
 class  (posteriorSampleStateClass), intent(inout) :: self
 integer                           , intent(in   ) :: chainIndex
end subroutine myImplementationChainIndexSet
```

`restore` Restore the state, one step at a time. Must have the following interface:

```
subroutine myImplementationRestore(self,stateVector,first)
 class           (posteriorSampleStateClass)              , intent(inout) :: self
 double precision                           , dimension(:), intent(in   ) :: &
&  stateVector
 logical                                                  , intent(in   ) :: first
end subroutine myImplementationRestore
```

`chainIndex` Return the index of the chain associated with this state. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationChainIndex(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end integer function myImplementationChainIndex
```

`acceptanceRate` Return the state acceptance rate. Must have the following interface:

```
double precision function myImplementationAcceptanceRate(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end double precision function myImplementationAcceptanceRate
```

`reset` Reset the state object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationReset(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end subroutine myImplementationReset
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`dimension` Returns the dimension of the state. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationDimension(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end integer function myImplementationDimension
```

`get` Get the current state vector. Must have the following interface:

```
double precision, dimension(self%parameterCount) function myImplementationGet(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end double precision, dimension(self%parameterCount) function myImplementationGet
```

`count` Returns the number of steps in the current state. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationCount(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end integer function myImplementationCount
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (posteriorSampleStateClass), intent(inout)          :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`variance` Return the variance in the state vector. Must have the following interface:

```
double precision, dimension(self%parameterCount) function myImplementationVariance(self&
&  )
 class(posteriorSampleStateClass), intent(inout) :: self
end double precision, dimension(self%parameterCount) function myImplementationVariance
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (posteriorSampleStateClass), intent(inout)           :: self
 type   (inputParameters          ), intent(inout)           :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`parameterCountSet` Set the number of parameters in this state. Must have the following interface:

```
subroutine myImplementationParameterCountSet(self,parameterCount)
 class  (posteriorSampleStateClass), intent(inout) :: self
 integer                           , intent(in   ) :: parameterCount
end subroutine myImplementationParameterCountSet
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleStateClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleStateClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`mean` Return the mean state. Must have the following interface:

```
double precision, dimension(self%parameterCount) function myImplementationMean(self)
 class(posteriorSampleStateClass), intent(inout) :: self
end double precision, dimension(self%parameterCount) function myImplementationMean
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleStateClass), intent(inout) :: self
 class(posteriorSampleStateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleStateClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`update` Update the state vector. Must have the following interface:

```
subroutine myImplementationUpdate(self,stateNew,logState,isConverged,outlierMask)
 class           (posteriorSampleStateClass)              , intent(inout)           :: &
&  self
 double precision                                 , dimension(:), intent(in   )           :: &
&  stateNew
 logical                                                        , intent(in   )           :: &
&  logState
 logical                                                        , intent(in   )           :: &
&  isConverged
 logical                                          , dimension(:), intent(in   ), optional :: &
&  outlierMask
 end subroutine myImplementationUpdate
```

Existing implementations are:

`posteriorSampleStateHistory` A posterior sampling state class which stores history.

`posteriorSampleStateSimple` A simple posterior sampling state class.

`posteriorSampleStateCorrelation` A correlation posterior sampling state class.

Posterior Sampling State Initialization

Additional implementations for posterior sampling state initialization are added using the `posteriorSampleStateInitialize` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleStateInitialize name="posteriorSampleStateInitializeMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleStateInitialize>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleStateInitializeMyImplementation`. The file *must* define a type that extends the

posteriorSampleStateInitializeClass class (or extends another type which is itself an extension of the posteriorSampleStateInitializeClass class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

hashedDescriptor Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (posteriorSampleStateInitializeClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

descriptor Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (posteriorSampleStateInitializeClass), intent(inout)           :: self
  type   (inputParameters                    ), intent(inout)           :: descriptor
  logical                                     , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

autoHook Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(posteriorSampleStateInitializeClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

stateStore Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (posteriorSampleStateInitializeClass), intent(inout) :: self
  integer                                     , intent(in   ) :: stateFile
  type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
  integer(c_size_t                           ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

initialize Initialize the state of the posterior sampler. Must have the following interface:

```
 subroutine myImplementationInitialize(self,simulationState,modelParameters_,&
&  modelLikelihood,timeEvaluatePrevious, logLikelihood, logPosterior)
  class           (posteriorSampleStateInitializeClass)              , intent(inout) :: &
&  self
  class           (posteriorSampleStateClass          )              , intent(inout) :: &
&  simulationState
  type            (modelParameterList                 ), dimension(:), intent(in   ) :: &
&  modelParameters_
  class           (posteriorSampleLikelihoodClass     )              , intent(inout) :: &
&  modelLikelihood
```

```
  double precision                                                    , intent(  out) :: &
&  timeEvaluatePrevious, logLikelihood, logPosterior
 end subroutine myImplementationInitialize
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (posteriorSampleStateInitializeClass)                          , intent(&
&  inout) :: self
  type     (varying_string                    ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                             )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(posteriorSampleStateInitializeClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(posteriorSampleStateInitializeClass), intent(inout) :: self
  class(posteriorSampleStateInitializeClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
  class  (posteriorSampleStateInitializeClass), intent(inout) :: self
  integer                                     , intent(in   ) :: stateFile
  type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
  integer(c_size_t                           ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleStateInitializePriorRandom` A posterior sampling state initialization class which samples the inital state at random from the priors.

`posteriorSampleStateInitializeSwitched` A posterior sampling state initialization class which sets initial state by switching between two other options.

`posteriorSampleStateInitializeResume` A posterior sampling state initialization class which sets initial state to that at the end of a previous simulation.

`posteriorSampleStateInitializeLatinHypercube` A posterior sampling state initialization class which samples the inital state at random from the priors using Latin Hypercube sampling.

Posterior Sampling StoppingCriterion Criteria

Additional implementations for posterior sampling stoppingcriterion criteria are added using the `posteriorSampleStoppingCr` class. The implementation should be placed in a file containing the directive:

```
!# <posteriorSampleStoppingCriterion name="posteriorSampleStoppingCriterionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </posteriorSampleStoppingCriterion>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `posteriorSampleStoppingCriterionMyImplementation`. The file *must* define a type that extends the `posteriorSampleStoppingCriterionClass` class (or extends another type which is itself an extension of the `posteriorSampleStoppingCriterionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (posteriorSampleStoppingCriterionClass), intent(inout)           :: self
  logical                                       , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (posteriorSampleStoppingCriterionClass), intent(inout)           :: self
  type   (inputParameters                      ), intent(inout)           :: descriptor
  logical                                       , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`stop` Returns true if the posterior sampling should stop. Must have the following interface:

```
 logical function myImplementationStop(self,simulationState)
  class(posteriorSampleStoppingCriterionClass), intent(inout) :: self
  class(posteriorSampleStateClass            ), intent(inout) :: simulationState
 end logical function myImplementationStop
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(posteriorSampleStoppingCriterionClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleStoppingCriterionClass), intent(inout) :: self
 integer                                       , intent(in   ) :: stateFile
 type   (fgsl_file                            ), intent(in   ) :: fgslStateFile
 integer(c_size_t                             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (posteriorSampleStoppingCriterionClass)                          , intent(&
&  inout) :: self
 type     (varying_string                       ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                                 )                          , intent(in&
&     ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(posteriorSampleStoppingCriterionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(posteriorSampleStoppingCriterionClass), intent(inout) :: self
 class(posteriorSampleStoppingCriterionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (posteriorSampleStoppingCriterionClass), intent(inout) :: self
 integer                                       , intent(in   ) :: stateFile
 type   (fgsl_file                            ), intent(in   ) :: fgslStateFile
 integer(c_size_t                             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`posteriorSampleStoppingCriterionStepCount` A posterior sampling stopping class which stepCount converges.

`posteriorSampleStoppingCriterionNever` A posterior sampling stopping class which never converges.

`posteriorSampleStoppingCriterionCorrelationLength` A posterior sampling stopping class which stops after a given number of correlation lengths.

Linear Theory Power Spectrum

Additional implementations for linear theory power spectrum are added using the `powerSpectrum` class. The implementation should be placed in a file containing the directive:

```
!# <powerSpectrum name="powerSpectrumMyImplementation">
!# <description>A short description of the implementation.</description>
!# </powerSpectrum>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `powerSpectrumMyImplementation`. The file *must* define a type that extends the `powerSpectrumClass` class (or extends another type which is itself an extension of the `powerSpectrumClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (powerSpectrumClass), intent(inout)           :: self
 logical                    , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (powerSpectrumClass), intent(inout)           :: self
 type   (inputParameters   ), intent(inout)           :: descriptor
 logical                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(powerSpectrumClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (powerSpectrumClass)                          , intent(inout) :: self
 type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*             )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`powerLogarithmicDerivative` Return the logarithmic derivative of the power spectrum, $\mathrm{d}\ln P(k)/\mathrm{d}\ln k$, for $k =$`wavenumber` [Mpc^{-1}]. Must have the following interface:

```
double precision function myImplementationPowerLogarithmicDerivative(self,wavenumber)
 class           (powerSpectrumClass), intent(inout) :: self
 double precision                    , intent(in   ) :: wavenumber
end double precision function myImplementationPowerLogarithmicDerivative
```

`powerDimensionless` Return the dimensionless linear power spectrum for $k =$`wavenumber` [Mpc^{-1}]. Must have the following interface:

```
double precision function myImplementationPowerDimensionless(self,wavenumber)
 class           (powerSpectrumClass), intent(inout) :: self
 double precision                    , intent(in   ) :: wavenumber
end double precision function myImplementationPowerDimensionless
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(powerSpectrumClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(powerSpectrumClass), intent(inout) :: self
 class(powerSpectrumClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`power` Return the linear power spectrum for $k =$`wavenumber` [Mpc^{-1}]. Must have the following interface:

```
double precision function myImplementationPower(self,wavenumber)
 class           (powerSpectrumClass), intent(inout) :: self
 double precision                    , intent(in   ) :: wavenumber
end double precision function myImplementationPower
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`powerSpectrumStandard` Provides a linear theory power spectrum class in which the power spectrum is just the transferred primordial power spectrum correctly normalized to $z = 0$.

Nonlinear Power Spectrum

Additional implementations for nonlinear power spectrum are added using the `powerSpectrumNonlinear` class. The implementation should be placed in a file containing the directive:

```
!# <powerSpectrumNonlinear name="powerSpectrumNonlinearMyImplementation">
!# <description>A short description of the implementation.</description>
!# </powerSpectrumNonlinear>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `powerSpectrumNonlinearMyImplementation`. The file *must* define a type that extends the `powerSpectrumNonlinearClass` class (or extends another type which is itself an extension of the `powerSpectrumNonlinearClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (powerSpectrumNonlinearClass), intent(inout)           :: self
 logical                             , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (powerSpectrumNonlinearClass), intent(inout)           :: self
 type   (inputParameters            ), intent(inout)           :: descriptor
 logical                             , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(powerSpectrumNonlinearClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`value` Return the nonlinear power spectrum for $k =$`wavenumber` [Mpc^{-1}] at cosmic time $t =$`time` [Gyr]. Must have the following interface:

```
double precision function myImplementationValue(self,wavenumber, time)
 class           (powerSpectrumNonlinearClass), intent(inout) :: self
 double precision                             , intent(in   ) :: wavenumber, time
end double precision function myImplementationValue
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumNonlinearClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (powerSpectrumNonlinearClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(powerSpectrumNonlinearClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(powerSpectrumNonlinearClass), intent(inout) :: self
 class(powerSpectrumNonlinearClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumNonlinearClass), intent(inout) :: self
 integer                             , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`powerSpectrumNonlinearPeacockDodds1996` Provides a nonlinear power spectrum class in which the power spectrum is computed using the algorithm of Peacock and Dodds [1996]. See §12.6.4.

`powerSpectrumNonlinearLinear` Provides a nonlinear power spectrum class in which the power spectrum equals the linear theory power spectrum. Intended primarily for testing purposes. See §12.6.4.

`powerSpectrumNonlinearCosmicEmu` Provides a nonlinear power spectrum class in which the power spectrum is computed using the code of Lawrence et al. [2010]. See §12.6.4.

Primordial Power Spectrum

Additional implementations for primordial power spectrum are added using the `powerSpectrumPrimordial` class. The implementation should be placed in a file containing the directive:

```
!# <powerSpectrumPrimordial name="powerSpectrumPrimordialMyImplementation">
!# <description>A short description of the implementation.</description>
!# </powerSpectrumPrimordial>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `powerSpectrumPrimordialMyImplementation`. The file *must* define a type that extends the `powerSpectrumPrimordialClass` class (or extends another type which is itself an extension of the `powerSpectrumPrimordialClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (powerSpectrumPrimordialClass), intent(inout)           :: self
 logical                              , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (powerSpectrumPrimordialClass), intent(inout)           :: self
 type   (inputParameters             ), intent(inout)           :: descriptor
 logical                              , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(powerSpectrumPrimordialClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumPrimordialClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`logarithmicDerivative` Return the logarithmic derivative with respect to wavenumber of the primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}. Must have the following interface:

```
double precision function myImplementationLogarithmicDerivative(self,wavenumber)
 class           (powerSpectrumPrimordialClass), intent(inout) :: self
 double precision                              , intent(in   ) :: wavenumber
end double precision function myImplementationLogarithmicDerivative
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (powerSpectrumPrimordialClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(powerSpectrumPrimordialClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(powerSpectrumPrimordialClass), intent(inout) :: self
 class(powerSpectrumPrimordialClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`power` Return the (unnormalized) power in the primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}. Must have the following interface:

```
double precision function myImplementationPower(self,wavenumber)
 class           (powerSpectrumPrimordialClass), intent(inout) :: self
 double precision                              , intent(in   ) :: wavenumber
end double precision function myImplementationPower
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumPrimordialClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`powerSpectrumPrimordialPowerLaw` Implements a power-law primordial power spectrum, possibly with a running index. It is defined by

$$P(k) \propto k^{n_\mathrm{s}+\ln(k/k_\mathrm{ref})[\mathrm{d}n/\mathrm{d}\ln k]}, \tag{16.9}$$

where the parameters are specified by input parameters $n_\mathrm{s} \equiv$ `[index]`, $k_\mathrm{ref} \equiv$ `[wavenumberReference]` and $\mathrm{d}n/\mathrm{d}\ln k \equiv$ `[running]`.

Transferred Primordial Power Spectrum

Additional implementations for transferred primordial power spectrum are added using the `powerSpectrumPrimordialTransf` class. The implementation should be placed in a file containing the directive:

```
!# <powerSpectrumPrimordialTransferred name="powerSpectrumPrimordialTransferredMyImplementation">
!# <description>A short description of the implementation.</description>
!# </powerSpectrumPrimordialTransferred>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `powerSpectrumPrimordialTransferredMyImplementation`. The file *must* define a type that extends the `powerSpectrumPrimordialTransferredClass` class (or extends another type which is itself an extension of the `powerSpectrumPrimordialTransferredClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (powerSpectrumPrimordialTransferredClass), intent(inout)           :: self
  logical                                         , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (powerSpectrumPrimordialTransferredClass), intent(inout)           :: self
  type   (inputParameters                        ), intent(inout)           :: &
&  descriptor
  logical                                         , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(powerSpectrumPrimordialTransferredClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumPrimordialTransferredClass), intent(inout) :: self
 integer                                         , intent(in   ) :: stateFile
 type   (fgsl_file                               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`logarithmicDerivative` Return the logarithmic derivative with respect to wavenumber of the transferred primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}. Must have the following interface:

```
double precision function myImplementationLogarithmicDerivative(self,wavenumber)
 class           (powerSpectrumPrimordialTransferredClass), intent(inout) :: self
 double precision                                         , intent(in   ) :: wavenumber
end double precision function myImplementationLogarithmicDerivative
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (powerSpectrumPrimordialTransferredClass)                          , intent(&
&  inout) :: self
 type     (varying_string                        ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                                 )                          , intent(&
&  in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(powerSpectrumPrimordialTransferredClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(powerSpectrumPrimordialTransferredClass), intent(inout) :: self
 class(powerSpectrumPrimordialTransferredClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`power` Return the (unnormalized) power in the transferred primordial power spectrum at the given `wavenumber` (specified in units of Mpc^{-1}. Must have the following interface:

```
double precision function myImplementationPower(self,wavenumber)
 class           (powerSpectrumPrimordialTransferredClass), intent(inout) :: self
 double precision                                         , intent(in   ) :: wavenumber
end double precision function myImplementationPower
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumPrimordialTransferredClass), intent(inout) :: self
 integer                                         , intent(in   ) :: stateFile
 type   (fgsl_file                               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`powerSpectrumPrimordialTransferredSimple` Implements a simple transferred primordial power spectrum.

Power Spectrum Window Functions

Additional implementations for power spectrum window functions are added using the `powerSpectrumWindowFunction` class. The implementation should be placed in a file containing the directive:

```
!# <powerSpectrumWindowFunction name="powerSpectrumWindowFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </powerSpectrumWindowFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `powerSpectrumWindowFunctionMyImplementation`. The file *must* define a type that extends the `powerSpectrumWindowFunctionClass` class (or extends another type which is itself an extension of the `powerSpectrumWindowFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (powerSpectrumWindowFunctionClass), intent(inout)          :: self
  logical                                  , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (powerSpectrumWindowFunctionClass), intent(inout)          :: self
 type   (inputParameters                 ), intent(inout)          :: descriptor
 logical                                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(powerSpectrumWindowFunctionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`value` Returns the window function for power spectrum variance computation at the specified `wavenumber` (in Mpc^{-1}) for a given `smoothingMass` (in $M_\odot$). Must have the following interface:

```
double precision function myImplementationValue(self,wavenumber, smoothingMass)
 class           (powerSpectrumWindowFunctionClass), intent(inout) :: self
 double precision                                  , intent(in   ) :: wavenumber, &
&  smoothingMass
 end double precision function myImplementationValue
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumWindowFunctionClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`amplitudeIsMassIndependent` Should return true if, and only if, the amplitude of the window function below the maximum wavenumber is independent of the smoothing mass scale. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationAmplitudeIsMassIndependent(self)
 class(powerSpectrumWindowFunctionClass), intent(inout) :: self
end logical function myImplementationAmplitudeIsMassIndependent
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (powerSpectrumWindowFunctionClass)                          , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`wavenumberMaximum` Returns the maximum wavenumber for which the window function for power spectrum variance computation is non-zero for a given `smoothingMass` (in $M_\odot$). Must have the following interface:

```
double precision function myImplementationWavenumberMaximum(self,smoothingMass)
 class           (powerSpectrumWindowFunctionClass), intent(inout) :: self
 double precision                                  , intent(in   ) :: smoothingMass
end double precision function myImplementationWavenumberMaximum
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(powerSpectrumWindowFunctionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(powerSpectrumWindowFunctionClass), intent(inout) :: self
 class(powerSpectrumWindowFunctionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (powerSpectrumWindowFunctionClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`powerSpectrumWindowFunctionTopHat` A top-hat in real space window function for filtering of power spectra.

`powerSpectrumWindowFunctionSharpKSpace` A sharp k-space window function for filtering of power spectra.

`powerSpectrumWindowFunctionLagrangianChan2017` A power spectrum window function class that implements the Lagrangian filter of Chan et al. [2017].

`powerSpectrumWindowFunctionTopHatSharpKHybrid` A hybrid top-hat/sharp k-space window function for filtering of power spectra.

`powerSpectrumWindowFunctionSmoothKSpace` A smooth window function for filtering of power spectra.

Radiation Fields

Additional implementations for radiation fields are added using the `radiationField` class. The implementation should be placed in a file containing the directive:

```
!# <radiationField name="radiationFieldMyImplementation">
!# <description>A short description of the implementation.</description>
!# </radiationField>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `radiationFieldMyImplementation`. The file *must* define a type that extends the `radiationFieldClass` class (or

extends another type which is itself an extension of the `radiationFieldClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (radiationFieldClass), intent(inout)           :: self
 logical                     , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (radiationFieldClass), intent(inout)           :: self
 type   (inputParameters    ), intent(inout)           :: descriptor
 logical                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(radiationFieldClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (radiationFieldClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`flux` Return the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation field. Must have the following interface:

```
double precision function myImplementationFlux(self,wavelength,node)
 class           (radiationFieldClass), intent(inout) :: self
 double precision                     , intent(in   ) :: wavelength
 type            (treeNode           ), intent(inout) :: node
end double precision function myImplementationFlux
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (radiationFieldClass)                          , intent(inout) :: self
```

```
  type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*              )                           , intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`integrateOverCrossSection` Integrates the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) of the given radiation structure between the wavelengths given in `wavelengthRange` over a cross section specified by the function `crossSectionFunction`. A default implementation exists. If overridden the following interface must be used:

```
 double precision function myImplementationIntegrateOverCrossSection(self,&
&  wavelengthRange,crossSectionFunction,node)
  class           (radiationFieldClass)              , intent(inout) :: self
  double precision                     , dimension(2), intent(in   ) :: wavelengthRange
  double precision                     , external                    :: &
&  crossSectionFunction
  type            (treeNode           )              , intent(inout) :: node
 end double precision function myImplementationIntegrateOverCrossSection
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(radiationFieldClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(radiationFieldClass), intent(inout) :: self
 class(radiationFieldClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (radiationFieldClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`radiationFieldNull` A radiation field class for null fields.

`radiationFieldIntergalacticBackground` A radiation field class for intergalactic background light with properties read from file.

`radiationFieldIntergalacticBackgroundInternal` A radiation field class for intergalactic background light with properties computed internally.

`radiationFieldIntergalacticBackgroundFile` A radiation field class for intergalactic background light with properties read from file.

`radiationFieldCosmicMicrowaveBackground` A radiation field class for the cosmic microwave background.

`radiationFieldSummation` A summation radiation field class.

`radiationFieldBlackBody` A radiation field class for blackbody fields.

Ram pressure stripping in disks

Additional implementations for ram pressure stripping in disks are added using the `ramPressureStrippingDisks` class. The implementation should be placed in a file containing the directive:

```
!# <ramPressureStrippingDisks name="ramPressureStrippingDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </ramPressureStrippingDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `ramPressureStrippingDisksMyImplementation`. The file *must* define a type that extends the `ramPressureStrippingDisksClass` class (or extends another type which is itself an extension of the `ramPressureStrippingDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (ramPressureStrippingDisksClass), intent(inout)           :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (ramPressureStrippingDisksClass), intent(inout)           :: self
 type   (inputParameters               ), intent(inout)           :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`rateMassLoss` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the disk component of `node`. Must have the following interface:

```
double precision function myImplementationRateMassLoss(self,node)
 class(ramPressureStrippingDisksClass), intent(inout) :: self
 type (treeNode                      ), intent(inout) :: node
end double precision function myImplementationRateMassLoss
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(ramPressureStrippingDisksClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (ramPressureStrippingDisksClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (ramPressureStrippingDisksClass)                          , intent(inout) ::&
&  self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) ::&
&  allowedParameters
 character(len=*                         )                          , intent(in   ) ::&
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(ramPressureStrippingDisksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(ramPressureStrippingDisksClass), intent(inout) :: self
 class(ramPressureStrippingDisksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (ramPressureStrippingDisksClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`ramPressureStrippingDisksNull` A null model of ram pressure stripping in galactic disks.

`ramPressureStrippingDisksSimple` A simple model of ram pressure stripping in galactic disks.

Ram pressure stripping in spheroids

Additional implementations for ram pressure stripping in spheroids are added using the `ramPressureStrippingSpheroids` class. The implementation should be placed in a file containing the directive:

```
!# <ramPressureStrippingSpheroids name="ramPressureStrippingSpheroidsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </ramPressureStrippingSpheroids>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `ramPressureStrippingSpheroidsMyImplementation`. The file *must* define a type that extends the `ramPressureStrippingSpheroidsClass` class (or extends another type which is itself an extension of the `ramPressureStrippingSpheroidsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (ramPressureStrippingSpheroidsClass), intent(inout)           :: self
  logical                                    , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (ramPressureStrippingSpheroidsClass), intent(inout)           :: self
 type   (inputParameters                   ), intent(inout)           :: descriptor
 logical                                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`rateMassLoss` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to ram pressure stripping of the spheroid component of `node`. Must have the following interface:

```
double precision function myImplementationRateMassLoss(self,node)
 class(ramPressureStrippingSpheroidsClass), intent(inout) :: self
 type (treeNode                          ), intent(inout) :: node
end double precision function myImplementationRateMassLoss
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(ramPressureStrippingSpheroidsClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (ramPressureStrippingSpheroidsClass), intent(inout) :: self
 integer                                    , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (ramPressureStrippingSpheroidsClass)                          , intent(inout&
&  ) :: self
 type     (varying_string                    ), allocatable, dimension(:), intent(inout&
&  ) :: allowedParameters
 character(len=*                             )                          , intent(in   &
&  ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(ramPressureStrippingSpheroidsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(ramPressureStrippingSpheroidsClass), intent(inout) :: self
 class(ramPressureStrippingSpheroidsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (ramPressureStrippingSpheroidsClass), intent(inout) :: self
 integer                                    , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`ramPressureStrippingSpheroidsSimple` A simple model of ram pressure stripping in galactic spheroids.

`ramPressureStrippingSpheroidsNull` A null model of ram pressure stripping in galactic spheroids.

Dynamical friction models.

Additional implementations for dynamical friction models. are added using the `satelliteDynamicalFriction` class. The implementation should be placed in a file containing the directive:

```
!# <satelliteDynamicalFriction name="satelliteDynamicalFrictionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </satelliteDynamicalFriction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `satelliteDynamicalFrictionMyImplementation`. The file *must* define a type that extends the `satelliteDynamicalFrictionClass` class (or extends another type which is itself an extension of the `satelliteDynamicalFrictionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (satelliteDynamicalFrictionClass), intent(inout)           :: self
  logical                                 , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (satelliteDynamicalFrictionClass), intent(inout)           :: self
 type   (inputParameters                ), intent(inout)           :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(satelliteDynamicalFrictionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`acceleration` Returns the satellite acceleration due to dynamical friction for `node` (in units of km/s/-Gyr). Must have the following interface:

```
double precision, dimension(3) function myImplementationAcceleration(self,node)
 class(satelliteDynamicalFrictionClass), intent(inout) :: self
 type (treeNode                       ), intent(inout) :: node
end double precision, dimension(3) function myImplementationAcceleration
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteDynamicalFrictionClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (satelliteDynamicalFrictionClass)                          , intent(inout) &
&  :: self
 type     (varying_string                ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                         )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(satelliteDynamicalFrictionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(satelliteDynamicalFrictionClass), intent(inout) :: self
 class(satelliteDynamicalFrictionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteDynamicalFrictionClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`satelliteDynamicalFrictionChandrasekhar1943` A satellite dynamical friction class which uses the model of Chandrasekhar [1943].

`satelliteDynamicalFrictionZero` A satellite dynamical friction class in which the acceleration is always zero.

Satellite Merging Timescales

Additional implementations for satellite merging timescales are added using the `satelliteMergingTimescales` class. The implementation should be placed in a file containing the directive:

```
!# <satelliteMergingTimescales name="satelliteMergingTimescalesMyImplementation">
!# <description>A short description of the implementation.</description>
!# </satelliteMergingTimescales>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `satelliteMergingTimescalesMyImplementation`. The file *must* define a type that extends the `satelliteMergingTimescalesClass` class (or extends another type which is itself an extension of the `satelliteMergingTimescalesClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (satelliteMergingTimescalesClass), intent(inout)          :: self
  logical                                 , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (satelliteMergingTimescalesClass), intent(inout)          :: self
 type   (inputParameters                ), intent(inout)          :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(satelliteMergingTimescalesClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteMergingTimescalesClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (satelliteMergingTimescalesClass)                          , intent(inout) &
&  :: self
 type     (varying_string                ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                         )                          , intent(in   ) &
&  :: sourceName
end subroutine myImplementationAllowedParameters
```

`timeUntilMerging` Return the time (in Gyr) until the satellite will merge with its host given the current orbit. Must have the following interface:

```
double precision function myImplementationTimeUntilMerging(self,node,orbit)
 class(satelliteMergingTimescalesClass), intent(inout) :: self
 type (treeNode                       ), intent(inout) :: node
 type (keplerOrbit                    ), intent(inout) :: orbit
end double precision function myImplementationTimeUntilMerging
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(satelliteMergingTimescalesClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(satelliteMergingTimescalesClass), intent(inout) :: self
 class(satelliteMergingTimescalesClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteMergingTimescalesClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`satelliteMergingTimescalesLaceyCole1993Tormen` Computes the merging timescale using the method of Lacey and Cole [1993] with a parameterization of orbital parameters designed to fit the results of Tormen [1997] as described by Cole et al. [2000]. See §12.51.1.

`satelliteMergingTimescalesZero` Returns a zero timescale for merging.

`satelliteMergingTimescalesVillalobos2013` Computes the merging timescale using the method of Villalobos et al. [2013] to modify another merging timescale method. See §12.51.1.

`satelliteMergingTimescalesWetzelWhite2010` Computes the merging timescale using the method of Wetzel and White [2010]. See §12.51.1.

`satelliteMergingTimescalesBoylanKolchin2008` Computes the merging timescale using the method of Boylan-Kolchin et al. [2008]. See §12.51.1.

`satelliteMergingTimescalesPreset` This class assumes that merging times have been preset for every node (or, at least, every node which becomes a satellite). It therefore simply returns the preset merging time. See §12.51.1.

`satelliteMergingTimescalesRandom` Returns a random timescale for merging.

`satelliteMergingTimescalesJiang2008` Computes the merging timescale using the method of Jiang et al. [2008]. See §12.51.1.

`satelliteMergingTimescalesInfinite` Returns an infinite timescale for merging. See §12.51.1.

`satelliteMergingTimescalesLaceyCole1993` Computes the merging timescale using the method of Lacey and Cole [1993]. See §12.51.1.

Satellite Orphan Distributions

Additional implementations for satellite orphan distributions are added using the `satelliteOrphanDistribution` class. The implementation should be placed in a file containing the directive:

```
!# <satelliteOrphanDistribution name="satelliteOrphanDistributionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </satelliteOrphanDistribution>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `satelliteOrphanDistributionMyImplementation`. The file *must* define a type that extends the `satelliteOrphanDistributionClass` class (or extends another type which is itself an extension of the `satelliteOrphanDistributionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (satelliteOrphanDistributionClass), intent(inout)          :: self
  logical                                  , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (satelliteOrphanDistributionClass), intent(inout)          :: self
 type   (inputParameters                ), intent(inout)          :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(satelliteOrphanDistributionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteOrphanDistributionClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`position` Return the position of the given orphan in physical coordinates. Must have the following interface:

```
double precision, dimension(3) function myImplementationPosition(self,node)
 class(satelliteOrphanDistributionClass), intent(inout) :: self
 type (treeNode                        ), intent(inout) :: node
end double precision, dimension(3) function myImplementationPosition
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (satelliteOrphanDistributionClass)                         , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`velocity` Return the peculiar velocity of the given orphan in physical coordinates. Must have the following interface:

```
double precision, dimension(3) function myImplementationVelocity(self,node)
 class(satelliteOrphanDistributionClass), intent(inout) :: self
 type (treeNode                        ), intent(inout) :: node
end double precision, dimension(3) function myImplementationVelocity
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(satelliteOrphanDistributionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(satelliteOrphanDistributionClass), intent(inout) :: self
 class(satelliteOrphanDistributionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteOrphanDistributionClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
 integer(c_size_t                        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`extent` The maximum extent of the distribution, i.e. the radius of a sphere centered on the host halo which encompasses all orphan satellites. Must have the following interface:

```
double precision function myImplementationExtent(self,node)
 class(satelliteOrphanDistributionClass), intent(inout) :: self
 type (treeNode                         ), intent(inout) :: node
end double precision function myImplementationExtent
```

Existing implementations are:

`satelliteOrphanDistributionTraceDarkMatter` An orphan satellite distribution which assumes an isotropic, random distribution with orphans tracing the radial distribution of dark matter.

`satelliteOrphanDistributionRandomIsotropic` An abstract orphan satellite distribution which assumes an isotropic, random distribution of positions, and velocities drawn from an isotropic normal distribution. The radial distribution and velocity dispersion must be specified by the child class.

Satellite halo tidal field models.

Additional implementations for satellite halo tidal field models. are added using the `satelliteTidalField` class. The implementation should be placed in a file containing the directive:

```
!# <satelliteTidalField name="satelliteTidalFieldMyImplementation">
!# <description>A short description of the implementation.</description>
!# </satelliteTidalField>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `satelliteTidalFieldMyImplementation`. The file *must* define a type that extends the `satelliteTidalFieldClass` class (or extends another type which is itself an extension of the `satelliteTidalFieldClass` class),

containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`tidalTensorRadial` Returns the radial component, $\Phi_{\rm rr}$, of the tidal tensor, $\Phi_{\rm ab}$. Must have the following interface:

```
double precision function myImplementationTidalTensorRadial(self,node)
 class(satelliteTidalFieldClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationTidalTensorRadial
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (satelliteTidalFieldClass), intent(inout)           :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (satelliteTidalFieldClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(satelliteTidalFieldClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteTidalFieldClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (satelliteTidalFieldClass)                          , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
```

```
  character(len=*                  )                          , intent(in   ) :: &
 &  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(satelliteTidalFieldClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(satelliteTidalFieldClass), intent(inout) :: self
 class(satelliteTidalFieldClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteTidalFieldClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`satelliteTidalFieldNull` A satellite tidal field class which computes the tidal field assuming no tidal field.

`satelliteTidalFieldSphericalSymmetry` A satellite tidal field class which computes the tidal field assuming spherical symmetry.

Satellite halo tidal heating rate models.

Additional implementations for satellite halo tidal heating rate models. are added using the `satelliteTidalHeatingRate` class. The implementation should be placed in a file containing the directive:

```
!# <satelliteTidalHeatingRate name="satelliteTidalHeatingRateMyImplementation">
!# <description>A short description of the implementation.</description>
!# </satelliteTidalHeatingRate>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `satelliteTidalHeatingRateMyImplementation`. The file *must* define a type that extends the `satelliteTidalHeatingRateClass` class (or extends another type which is itself an extension of the `satelliteTidalHeatingRateClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`heatingRate` Return the satellite tidal heating rate for `node` (in units of $(\mathrm{km/s/Mpc})^2/\mathrm{Gyr}$). Must have the following interface:

```
double precision function myImplementationHeatingRate(self,node)
 class(satelliteTidalHeatingRateClass), intent(inout) :: self
 type (treeNode                      ), intent(inout) :: node
end double precision function myImplementationHeatingRate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (satelliteTidalHeatingRateClass), intent(inout)           :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (satelliteTidalHeatingRateClass), intent(inout)           :: self
 type   (inputParameters               ), intent(inout)           :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(satelliteTidalHeatingRateClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteTidalHeatingRateClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (satelliteTidalHeatingRateClass)                          , intent(inout) ::&
&   self
 type     (varying_string                ), allocatable, dimension(:), intent(inout) ::&
&   allowedParameters
 character(len=*                         )                          , intent(in   ) ::&
&   sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(satelliteTidalHeatingRateClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(satelliteTidalHeatingRateClass), intent(inout) :: self
 class(satelliteTidalHeatingRateClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteTidalHeatingRateClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`satelliteTidalHeatingRateZero` A satellite tidal heating rate class which implements a tidal heating rate model in which the heating rate is always zero.

`satelliteTidalHeatingRateGnedin1999` A satellite tidal heating rate class which implements the tidal heating rate model of Gnedin et al. [1999].

Tidal stripping models for satellites.

Additional implementations for tidal stripping models for satellites. are added using the `satelliteTidalStripping` class. The implementation should be placed in a file containing the directive:

```
!# <satelliteTidalStripping name="satelliteTidalStrippingMyImplementation">
!# <description>A short description of the implementation.</description>
!# </satelliteTidalStripping>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `satelliteTidalStrippingMyImplementation`. The file *must* define a type that extends the `satelliteTidalStrippingClass` class (or extends another type which is itself an extension of the `satelliteTidalStrippingClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (satelliteTidalStrippingClass), intent(inout)          :: self
  logical                              , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (satelliteTidalStrippingClass), intent(inout)          :: self
 type   (inputParameters             ), intent(inout)          :: descriptor
 logical                              , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(satelliteTidalStrippingClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteTidalStrippingClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (satelliteTidalStrippingClass)                          , intent(inout) :: &
&  self
 type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`massLossRate` Returns the rate of tidal mass loss for `node` (in units of $M_\odot$/Gyr). Must have the following interface:

```
double precision function myImplementationMassLossRate(self,node)
 class(satelliteTidalStrippingClass), intent(inout)         :: self
 type (treeNode                    ), intent(inout), target :: node
end double precision function myImplementationMassLossRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(satelliteTidalStrippingClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(satelliteTidalStrippingClass), intent(inout) :: self
 class(satelliteTidalStrippingClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (satelliteTidalStrippingClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`satelliteTidalStrippingZero` A satellite tidal stripping class in which the stripping rate is always zero.

`satelliteTidalStrippingZentner2005` A satellite tidal stripping class which follows the model of Zentner et al. [2005].

Expulsive feedback from star formation in disks

Additional implementations for expulsive feedback from star formation in disks are added using the `starFormationExpulsiveFeedbackDisks` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationExpulsiveFeedbackDisks name="starFormationExpulsiveFeedbackDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationExpulsiveFeedbackDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationExpulsiveFeedbackDisksMyImplementation`. The file *must* define a type that extends the `starFormationExpulsiveFeedbackDisksClass` class (or extends another type which is itself an extension of the `starFormationExpulsiveFeedbackDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationExpulsiveFeedbackDisksClass), intent(inout)          :: self
  logical                                          , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (starFormationExpulsiveFeedbackDisksClass), intent(inout)          :: self
  type   (inputParameters                         ), intent(inout)          :: &
&  descriptor
  logical                                          , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(starFormationExpulsiveFeedbackDisksClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (starFormationExpulsiveFeedbackDisksClass), intent(inout) :: self
  integer                                          , intent(in   ) :: stateFile
  type   (fgsl_file                                ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                 ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`outflowRate` Returns the outflow rate due to star formation in the disk component of `node` in units of $M_\odot$/Gyr. Must have the following interface:

```
 double precision function myImplementationOutflowRate(self,node,rateEnergyInput, &
&  rateStarFormation)
  class           (starFormationExpulsiveFeedbackDisksClass), intent(inout) :: self
  type            (treeNode                                ), intent(inout) :: node
  double precision                                          , intent(in   ) :: &
&  rateEnergyInput, rateStarFormation
 end double precision function myImplementationOutflowRate
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (starFormationExpulsiveFeedbackDisksClass)                          , intent&
&  (inout) :: self
  type     (varying_string                          ), allocatable, dimension(:), intent&
&  (inout) :: allowedParameters
```

```
     character(len=*                                    )                          , intent&
    &  (in   ) :: sourceName
     end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationExpulsiveFeedbackDisksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationExpulsiveFeedbackDisksClass), intent(inout) :: self
 class(starFormationExpulsiveFeedbackDisksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationExpulsiveFeedbackDisksClass), intent(inout) :: self
 integer                                          , intent(in   ) :: stateFile
 type   (fgsl_file                                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationExpulsiveFeedbackDisksZero` A zero expulsive outflow rate due to star formation feedback in galactic disks.

`starFormationExpulsiveFeedbackDisksSuperWind` A superwind expulsive outflow rate due to star formation feedback in galactic disks.

Epulsive feedback from star formation in spheroids

Additional implementations for epulsive feedback from star formation in spheroids are added using the `starFormationExpulsiveFeedbackSpheroids` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationExpulsiveFeedbackSpheroids name="starFormationExpulsiveFeedbackSpheroidsMyImplementatio
!# <description>A short description of the implementation.</description>
!# </starFormationExpulsiveFeedbackSpheroids>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationExpulsiveFeedbackSpheroidsMyImplementation`. The file *must* define a type that extends the `starFormationExpulsiveFeedbackSpheroidsClass` class (or extends another type which is itself an extension of the `starFormationExpulsiveFeedbackSpheroidsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationExpulsiveFeedbackSpheroidsClass), intent(inout)           :: self
  logical                                              , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (starFormationExpulsiveFeedbackSpheroidsClass), intent(inout)           :: self
  type   (inputParameters                              ), intent(inout)           :: &
&  descriptor
  logical                                              , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: self
  integer                                              , intent(in   ) :: stateFile
  type   (fgsl_file                                    ), intent(in   ) :: fgslStateFile
  integer(c_size_t                                     ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateStore
```

`outflowRate` Returns the outflow rate due to star formation in the spheroid component of `node` in units of $M_\odot$/Gyr. Must have the following interface:

```
 double precision function myImplementationOutflowRate(self,node,rateEnergyInput, &
&  rateStarFormation)
  class           (starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: self
  type            (treeNode                                    ), intent(inout) :: node
  double precision                                              , intent(in   ) :: &
&  rateEnergyInput, rateStarFormation
 end double precision function myImplementationOutflowRate
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (starFormationExpulsiveFeedbackSpheroidsClass)                          , &
&  intent(inout) :: self
  type     (varying_string                              ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
  character(len=*                                       )                          , &
&  intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: self
 class(starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationExpulsiveFeedbackSpheroidsClass), intent(inout) :: self
 integer                                              , intent(in   ) :: stateFile
 type   (fgsl_file                                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                     ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationExpulsiveFeedbackSpheroidsSuperWind` A superwind expulsive outflow rate due to star formation feedback in galactic spheroids.

`starFormationExpulsiveFeedbackSpheroidsZero` A zero expulsive outflow rate due to star formation feedback in galactic spheroids.

Feedback from star formation in disks

Additional implementations for feedback from star formation in disks are added using the `starFormationFeedbackDisks` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationFeedbackDisks name="starFormationFeedbackDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationFeedbackDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationFeedbackDisksMyImplementation`. The file *must* define a type that extends the `starFormationFeedbackDisksClass` class (or extends another type which is itself an extension of the `starFormationFeedbackDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationFeedbackDisksClass), intent(inout)           :: self
  logical                                 , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (starFormationFeedbackDisksClass), intent(inout)           :: self
 type   (inputParameters                ), intent(inout)           :: descriptor
 logical                                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(starFormationFeedbackDisksClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationFeedbackDisksClass), intent(inout) :: self
 integer                                 , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`outflowRate` Returns the outflow rate due to star formation in the disk component of `node` in units of $M_\odot$/Gyr. Must have the following interface:

```
 double precision function myImplementationOutflowRate(self,node,rateEnergyInput, &
&  rateStarFormation)
  class           (starFormationFeedbackDisksClass), intent(inout) :: self
  type            (treeNode                       ), intent(inout) :: node
```

```
  double precision                                , intent(in   ) :: rateEnergyInput, &
&  rateStarFormation
 end double precision function myImplementationOutflowRate
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (starFormationFeedbackDisksClass)                          , intent(inout) &
&  :: self
  type     (varying_string                ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
  character(len=*                         )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(starFormationFeedbackDisksClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(starFormationFeedbackDisksClass), intent(inout) :: self
  class(starFormationFeedbackDisksClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
  class  (starFormationFeedbackDisksClass), intent(inout) :: self
  integer                                 , intent(in   ) :: stateFile
  type   (fgsl_file                       ), intent(in   ) :: fgslStateFile
  integer(c_size_t                        ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationFeedbackDisksVlctyMxSclng` An outflow rate due to star formation feedback in galactic disks which scales with peak halo velocity.

`starFormationFeedbackDisksCreasey2012` The Creasey et al. [2012] outflow rate due to star formation feedback in galactic disks.

`starFormationFeedbackDisksHaloScaling` An outflow rate due to star formation feedback in galactic disks which scales with halo velocity.

`starFormationFeedbackDisksFixed` A fixed fraction outflow rate due to star formation feedback in galactic disks.

`starFormationFeedbackDisksPowerLawRedshiftScaling` A power-law outflow rate due to star formation feedback in galactic disks in which the characteristic velocity scales as a power of $(1+z)$.

`starFormationFeedbackDisksPowerLaw` A power-law outflow rate due to star formation feedback in galactic disks.

Feedback from star formation in spheroids

Additional implementations for feedback from star formation in spheroids are added using the `starFormationFeedbackSphero` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationFeedbackSpheroids name="starFormationFeedbackSpheroidsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationFeedbackSpheroids>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationFeedbackSpheroidsMyImplementation`. The file *must* define a type that extends the `starFormationFeedbackSpheroidsClass` class (or extends another type which is itself an extension of the `starFormationFeedbackSpheroidsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationFeedbackSpheroidsClass), intent(inout)           :: self
  logical                                     , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (starFormationFeedbackSpheroidsClass), intent(inout)           :: self
 type   (inputParameters                    ), intent(inout)           :: descriptor
 logical                                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(starFormationFeedbackSpheroidsClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationFeedbackSpheroidsClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`outflowRate` Returns the outflow rate due to star formation in the spheroid component of `node` in units of $M_\odot$/Gyr. Must have the following interface:

```
double precision function myImplementationOutflowRate(self,node,rateEnergyInput, &
&  rateStarFormation)
 class           (starFormationFeedbackSpheroidsClass), intent(inout) :: self
 type            (treeNode                           ), intent(inout) :: node
 double precision                                     , intent(in   ) :: &
&  rateEnergyInput, rateStarFormation
 end double precision function myImplementationOutflowRate
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (starFormationFeedbackSpheroidsClass)                          , intent(&
&  inout) :: self
 type     (varying_string                     ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
 character(len=*                              )                          , intent(in  &
&   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationFeedbackSpheroidsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationFeedbackSpheroidsClass), intent(inout) :: self
 class(starFormationFeedbackSpheroidsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationFeedbackSpheroidsClass), intent(inout) :: self
 integer                                     , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationFeedbackSpheroidsVlctyMxSclng` An outflow rate due to star formation feedback in galactic spheroids which scales with peak halo velocity.

`starFormationFeedbackSpheroidsPowerLawRedshiftScaling` A power-law outflow rate due to star formation feedback in galactic spheroids in which the characteristic velocity scales as a power of $(1+z)$.

`starFormationFeedbackSpheroidsPowerLaw` A power-law outflow rate due to star formation feedback in galactic spheroids.

`starFormationFeedbackSpheroidsFixed` A fixed fraction outflow rate due to star formation feedback in galactic spheroids.

Star Formation Histories

Additional implementations for star formation histories are added using the `starFormationHistory` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationHistory name="starFormationHistoryMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationHistory>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationHistoryMyImplementation`. The file *must* define a type that extends the `starFormationHistoryClass` class (or extends another type which is itself an extension of the `starFormationHistoryClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`create` Create the star formation history object. Must have the following interface:

```
subroutine myImplementationCreate(self,node,historyStarFormation,timeBegin)
 class           (starFormationHistoryClass), intent(inout) :: self
 type            (treeNode                 ), intent(inout) :: node
 type            (history                  ), intent(inout) :: historyStarFormation
 double precision                            , intent(in   ) :: timeBegin
end subroutine myImplementationCreate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (starFormationHistoryClass), intent(inout)          :: self
 logical                           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (starFormationHistoryClass), intent(inout)          :: self
 type   (inputParameters          ), intent(inout)          :: descriptor
 logical                           , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(starFormationHistoryClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationHistoryClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (starFormationHistoryClass)                          , intent(inout) :: self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`output` Output the star formation history. Must have the following interface:

```
 subroutine myImplementationOutput(self,node,nodePassesFilter,historyStarFormation,&
&  indexOutput,indexTree,labelComponent)
  class    (starFormationHistoryClass), intent(inout)         :: self
  type     (treeNode                 ), intent(inout), target :: node
  logical                             , intent(in   )         :: nodePassesFilter
  type     (history                  ), intent(inout)         :: historyStarFormation
  integer  (c_size_t                 ), intent(in   )         :: indexOutput
  integer  (kind=kind_int8           ), intent(in   )         :: indexTree
  character(len=*                    ), intent(in   )         :: labelComponent
 end subroutine myImplementationOutput
```

`rate` Record the rate of star formation in this history. Must have the following interface:

```
 subroutine myImplementationRate(self,node,historyStarFormation,abundancesFuel,&
&  rateStarFormation)
  class           (starFormationHistoryClass), intent(inout) :: self
  type            (treeNode                 ), intent(inout) :: node
  type            (history                  ), intent(inout) :: historyStarFormation
  type            (abundances               ), intent(in   ) :: abundancesFuel
```

```
 double precision                            , intent(in   ) :: rateStarFormation
end subroutine myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationHistoryClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationHistoryClass), intent(inout) :: self
 class(starFormationHistoryClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationHistoryClass), intent(inout) :: self
 integer                           , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`scales` Set ODE solver absolute scales for a star formation history object. Must have the following interface:

```
subroutine myImplementationScales(self,historyStarFormation,massStellar,&
&  abundancesStellar)
 class           (starFormationHistoryClass), intent(inout) :: self
 type            (history                  ), intent(inout) :: historyStarFormation
 double precision                           , intent(in   ) :: massStellar
 type            (abundances               ), intent(in   ) :: abundancesStellar
end subroutine myImplementationScales
```

Existing implementations are:

`starFormationHistoryMetallicitySplit` A star formation histories class which records star formation split by metallicity.

`starFormationHistoryNull` A null star formation histories class.

`starFormationHistoryInSitu` A star formation histories class which records *in situ* star formation.

Surface density rates of star formation in disks.

Additional implementations for surface density rates of star formation in disks. are added using the `starFormationRateSurfaceDensityDisks` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationRateSurfaceDensityDisks name="starFormationRateSurfaceDensityDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationRateSurfaceDensityDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationRateSurfaceDensityDisksMyImplementation`. The file *must* define a type that extends the `starFormationRateSurfaceDensityDisksClass` class (or extends another type which is itself an extension of the `starFormationRateSurfaceDensityDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationRateSurfaceDensityDisksClass), intent(inout)           :: self
  logical                                           , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (starFormationRateSurfaceDensityDisksClass), intent(inout)           :: self
  type   (inputParameters                           ), intent(inout)           :: &
&  descriptor
  logical                                            , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`unchanged` Return true if the surface density rate of star formation is unchanged since the previous evaluation. A default implementation exists. If overridden the following interface must be used:

```
 logical function myImplementationUnchanged(self,node)
  class(starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
  type (treeNode                                 ), intent(inout) :: node
 end logical function myImplementationUnchanged
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
 integer                                           , intent(in   ) :: stateFile
 type   (fgsl_file                                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (starFormationRateSurfaceDensityDisksClass)                          , &
&  intent(inout) :: self
 type     (varying_string                           ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
 character(len=*                                    )                          , &
&  intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`rate` Returns the star formation rate surface density (in $M_\odot$ Gyr^{-1} Mpc^{-2}) in the disk component of `thisNode` at the given `radius`. Must have the following interface:

```
double precision function myImplementationRate(self,node,radius)
 class           (starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
 type            (treeNode                                 ), intent(inout) :: node
 double precision                                           , intent(in   ) :: radius
end double precision function myImplementationRate
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
 class(starFormationRateSurfaceDensityDisksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`intervals` Return a set of integration intervals to use when integrating over the surface density of star formation rate. A default implementation exists. If overridden the following interface must be used:

```
double precision, allocatable, dimension(:,:) function myImplementationIntervals(self,&
&  node,radiusInner, radiusOuter)
 class           (starFormationRateSurfaceDensityDisksClass), intent(inout)         :: &
&  self
 type            (treeNode                                 ), intent(inout), target :: &
&  node
 double precision                                           , intent(in   )         :: &
&  radiusInner, radiusOuter
 end double precision, allocatable, dimension(:,:) function myImplementationIntervals
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationRateSurfaceDensityDisksClass), intent(inout) :: self
 integer                                           , intent(in   ) :: stateFile
 type   (fgsl_file                                 ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                  ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationRateSurfaceDensityDisksExtendedSchmidt` The extended Schmidt star formation rate surface density law of Shi et al. [2011] for galactic disks.

`starFormationRateSurfaceDensityDisksBlitz2006` The Blitz and Rosolowsky [2006] star formation rate surface density law for galactic disks.

`starFormationRateSurfaceDensityDisksKrumholz2009` The Krumholz et al. [2009] star formation rate surface density law for galactic disks.

`starFormationRateSurfaceDensityDisksKennicuttSchmidt` A Kennicutt-Schmidt star formation rate surface density for galactic disks.

Timescales for star formation in disks

Additional implementations for timescales for star formation in disks are added using the `starFormationTimescaleDisks` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationTimescaleDisks name="starFormationTimescaleDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationTimescaleDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationTimescaleDisksMyImplementation`. The file *must* define a type that extends the `starFormationTimescaleDisksClass` class (or extends another type which is itself an extension of the `starFormationTimescaleDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationTimescaleDisksClass), intent(inout)           :: self
  logical                                  , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (starFormationTimescaleDisksClass), intent(inout)           :: self
 type   (inputParameters                 ), intent(inout)           :: descriptor
 logical                                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(starFormationTimescaleDisksClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationTimescaleDisksClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (starFormationTimescaleDisksClass)                          , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`timescale` Returns the timescale (in Gyr) for star formation in the disk component of `node`. Must have the following interface:

```
double precision function myImplementationTimescale(self,node)
 class(starFormationTimescaleDisksClass), intent(inout)         :: self
 type (treeNode                        ), intent(inout), target :: node
end double precision function myImplementationTimescale
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationTimescaleDisksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationTimescaleDisksClass), intent(inout) :: self
 class(starFormationTimescaleDisksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationTimescaleDisksClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationTimescaleDisksBaugh2005` The Baugh et al. [2005] timescale for star formation in galactic disks.

`starFormationTimescaleDisksIntgrtdSurfaceDensity` A timescale for star formation in galactic disks which computes the timescale by integrating a star formation rate over the disk.

`starFormationTimescaleDisksHaloScaling` A haloScaling timescale for star formation feedback in galactic disks.

`starFormationTimescaleDisksFixed` A fixed timescale for star formation in galactic disks.

`starFormationTimescaleDisksVelocityMaxScaling` A velocityMaxScaling timescale for star formation in galactic disks.

`starFormationTimescaleDisksDynamicalTime` A timescale for star formation in galactic disks which scales with the disk dynamical time.

Timescales for star formation in spheroids

Additional implementations for timescales for star formation in spheroids are added using the `starFormationTimescaleSpher` class. The implementation should be placed in a file containing the directive:

```
!# <starFormationTimescaleSpheroids name="starFormationTimescaleSpheroidsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </starFormationTimescaleSpheroids>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `starFormationTimescaleSpheroidsMyImplementation`. The file *must* define a type that extends the `starFormationTimescaleSpheroidsClass` class (or extends another type which is itself an extension of the `starFormationTimescaleSpheroidsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (starFormationTimescaleSpheroidsClass), intent(inout)           :: self
  logical                                      , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (starFormationTimescaleSpheroidsClass), intent(inout)           :: self
  type   (inputParameters                     ), intent(inout)           :: descriptor
  logical                                      , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(starFormationTimescaleSpheroidsClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (starFormationTimescaleSpheroidsClass), intent(inout) :: self
  integer                                      , intent(in   ) :: stateFile
  type   (fgsl_file                           ), intent(in   ) :: fgslStateFile
  integer(c_size_t                            ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (starFormationTimescaleSpheroidsClass)                          , intent(&
&  inout) :: self
  type     (varying_string                      ), allocatable, dimension(:), intent(&
&  inout) :: allowedParameters
  character(len=*                               )                          , intent(in &
&    ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`timescale` Returns the timescale (in Gyr) for star formation in the spheroid component of `node`. Must have the following interface:

```
double precision function myImplementationTimescale(self,node)
 class(starFormationTimescaleSpheroidsClass), intent(inout)         :: self
 type (treeNode                            ), intent(inout), target :: node
end double precision function myImplementationTimescale
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(starFormationTimescaleSpheroidsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(starFormationTimescaleSpheroidsClass), intent(inout) :: self
 class(starFormationTimescaleSpheroidsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (starFormationTimescaleSpheroidsClass), intent(inout) :: self
 integer                                      , intent(in   ) :: stateFile
 type   (fgsl_file                            ), intent(in   ) :: fgslStateFile
 integer(c_size_t                             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`starFormationTimescaleSpheroidsVelocityMaxScaling` A velocityMaxScaling timescale for star formation in galactic spheroids.

`starFormationTimescaleSpheroidsDynamicalTime` A timescale for star formation in galactic spheroids which scales with the spheroid dynamical time.

Stellar Astrophysics

Additional implementations for stellar astrophysics are added using the `stellarAstrophysics` class. The implementation should be placed in a file containing the directive:

```
!# <stellarAstrophysics name="stellarAstrophysicsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarAstrophysics>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarAstrophysics-MyImplementation`. The file *must* define a type that extends the `stellarAstrophysicsClass` class (or extends another type which is itself an extension of the `stellarAstrophysicsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`massEjected` Returns the mass ejected by a star of given `massInitial` and `metallicity`. Must have the following interface:

```
double precision function myImplementationMassEjected(self,massInitial,metallicity)
 class           (stellarAstrophysicsClass), intent(inout) :: self
 double precision                          , intent(in   ) :: massInitial, metallicity
end double precision function myImplementationMassEjected
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (stellarAstrophysicsClass), intent(inout)           :: self
 logical                          , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (stellarAstrophysicsClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarAstrophysicsClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarAstrophysicsClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`lifetime` Returns the lifetime of a star of given `massInitial` and `metallicity`. Must have the following interface:

```
double precision function myImplementationLifetime(self,massInitial, metallicity)
 class           (stellarAstrophysicsClass), intent(inout) :: self
 double precision                          , intent(in   ) :: massInitial, metallicity
end double precision function myImplementationLifetime
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (stellarAstrophysicsClass)                          , intent(inout) :: self
  type     (varying_string         ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                  )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`massYield` Returns the metal mass yielded by a star of given `massInitial` and `metallicity`. Must have the following interface:

```
 double precision function myImplementationMassYield(self,massInitial, metallicity,&
&  atomIndex)
  class           (stellarAstrophysicsClass), intent(inout)           :: self
  double precision                          , intent(in   )           :: massInitial, &
&  metallicity
  integer                                   , intent(in   ), optional :: atomIndex
 end double precision function myImplementationMassYield
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarAstrophysicsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`massInitial` Returns the initial mass of a star of given `lifetime` and `metallicity`. Must have the following interface:

```
double precision function myImplementationMassInitial(self,lifetime, metallicity)
 class           (stellarAstrophysicsClass), intent(inout) :: self
 double precision                          , intent(in   ) :: lifetime, metallicity
end double precision function myImplementationMassInitial
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarAstrophysicsClass), intent(inout) :: self
 class(stellarAstrophysicsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarAstrophysicsClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarAstrophysicsFile` A stellar astrophysics class in which the stellar properties are read from file and interpolated.

Stellar Feedback

Additional implementations for stellar feedback are added using the `stellarFeedback` class. The implementation should be placed in a file containing the directive:

```
!# <stellarFeedback name="stellarFeedbackMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarFeedback>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarFeedbackMyImplementation`. The file *must* define a type that extends the `stellarFeedbackClass` class (or extends another type which is itself an extension of the `stellarFeedbackClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (stellarFeedbackClass), intent(inout)           :: self
 logical                      , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (stellarFeedbackClass), intent(inout)           :: self
 type   (inputParameters     ), intent(inout)           :: descriptor
 logical                      , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarFeedbackClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarFeedbackClass), intent(inout) :: self
 integer                      , intent(in   ) :: stateFile
 type   (fgsl_file           ), intent(in   ) :: fgslStateFile
 integer(c_size_t            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarFeedbackClass)                          , intent(inout) :: self
 type     (varying_string      ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*               )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`energyInputCumulative` Return the cumulative energy input from a stellar population of the given `initialMass`, `age`, and `metallicity`. Must have the following interface:

```
double precision function myImplementationEnergyInputCumulative(self,initialMass, age, &
&  metallicity)
 class           (stellarFeedbackClass), intent(inout) :: self
 double precision                      , intent(in   ) :: initialMass, age, metallicity
end double precision function myImplementationEnergyInputCumulative
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarFeedbackClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarFeedbackClass), intent(inout) :: self
 class(stellarFeedbackClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarFeedbackClass), intent(inout) :: self
 integer                      , intent(in   ) :: stateFile
 type   (fgsl_file           ), intent(in   ) :: fgslStateFile
 integer(c_size_t            ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarFeedbackStandard` A stellar feedback class which performs a simple calculation of energy feedback from stellar populations.

Stellar Populations

Additional implementations for stellar populations are added using the `stellarPopulation` class. The implementation should be placed in a file containing the directive:

```
!# <stellarPopulation name="stellarPopulationMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarPopulation>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarPopulation-MyImplementation`. The file *must* define a type that extends the `stellarPopulationClass` class (or extends another type which is itself an extension of the `stellarPopulationClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`uniqueID` Return the uniqueID corresponding to this population. A default implementation exists. If overridden the following interface must be used:

```
integer(c_size_t) function myImplementationUniqueID(self)
 class(stellarPopulationClass), intent(inout) :: self
end integer(c_size_t) function myImplementationUniqueID
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (stellarPopulationClass), intent(inout)           :: self
 logical                        , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (stellarPopulationClass), intent(inout)           :: self
 type   (inputParameters       ), intent(inout)           :: descriptor
 logical                        , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarPopulationClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`rateRecycling` Return the rate of recycling from this population. Must have the following interface:

```
double precision function myImplementationRateRecycling(self,abundances_,ageMinimum , &
&  ageMaximum)
 class           (stellarPopulationClass), intent(inout) :: self
 type            (abundances            ), intent(in   ) :: abundances_
 double precision                        , intent(in   ) :: ageMinimum, ageMaximum
end double precision function myImplementationRateRecycling
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarPopulationClass)                            , intent(inout) :: self
 type     (varying_string        ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                            , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`rateEnergy` Return the rate of energy input from this population. Must have the following interface:

```
double precision function myImplementationRateEnergy(self,abundances_,ageMinimum , &
&  ageMaximum)
 class           (stellarPopulationClass), intent(inout) :: self
 type            (abundances            ), intent(in   ) :: abundances_
 double precision                        , intent(in   ) :: ageMinimum, ageMaximum
end double precision function myImplementationRateEnergy
```

`spectra` Return at set of stellar spectra for this population. Must have the following interface:

```
class(stellarPopulationSpectraClass) function myImplementationSpectra(self)
 class(stellarPopulationClass), intent(inout) :: self
end class(stellarPopulationSpectraClass) function myImplementationSpectra
```

`recycledFractionInstantaneous` Return the recycled fraction from this population in the instantaneous approximation. Must have the following interface:

```
double precision function myImplementationRecycledFractionInstantaneous(self)
 class(stellarPopulationClass), intent(inout) :: self
end double precision function myImplementationRecycledFractionInstantaneous
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarPopulationClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarPopulationClass), intent(inout) :: self
 class(stellarPopulationClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`rateYield` Return the rate of element yield from this population. Must have the following interface:

```
 double precision function myImplementationRateYield(self,abundances_,ageMinimum  , &
&  ageMaximum,elementIndex)
  class           (stellarPopulationClass), intent(inout)          :: self
  type            (abundances            ), intent(in   )          :: abundances_
  double precision                         , intent(in   )          :: ageMinimum, &
&  ageMaximum
  integer                                  , intent(in   ), optional :: elementIndex
 end double precision function myImplementationRateYield
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationClass), intent(inout) :: self
 integer                        , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`yieldInstantaneous` Return the metal yield from this population in the instantaneous approximation. Must have the following interface:

```
double precision function myImplementationYieldInstantaneous(self)
 class(stellarPopulationClass), intent(inout) :: self
end double precision function myImplementationYieldInstantaneous
```

Existing implementations are:

`stellarPopulationStandard` A standard stellar population class.

Stellar Population Properties

Additional implementations for stellar population properties are added using the `stellarPopulationProperties` class. The implementation should be placed in a file containing the directive:

```
!# <stellarPopulationProperties name="stellarPopulationPropertiesMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarPopulationProperties>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarPopulationPropertiesMyImplementation`. The file *must* define a type that extends the `stellarPopulationPropertiesClass` class (or extends another type which is itself an extension of the `stellarPopulationPropertiesClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarPopulationPropertiesClass), intent(inout)          :: self
  logical                                  , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (stellarPopulationPropertiesClass), intent(inout)          :: self
  type   (inputParameters                 ), intent(inout)          :: descriptor
  logical                                  , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(stellarPopulationPropertiesClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`rates` Returns rates of change of stellar population properties. Must have the following interface:

```
 subroutine myImplementationRates(self,rateStarFormation,abundancesFuel,component,node,&
&  history_,rateMassStellar             , rateMassFuel         , rateEnergyInput,&
&  rateAbundancesFuel          , rateAbundancesStellar,rateLuminosityStellar,&
&  computeRateLuminosityStellar)
  class           (stellarPopulationPropertiesClass), intent(inout) :: self
  double precision                                  , intent(in   ) :: rateStarFormation
  type            (abundances                      ), intent(in   ) :: abundancesFuel
  class           (nodeComponent                   ), intent(in   ) :: component
  type            (treeNode                        ), intent(inout) :: node
  type            (history                         ), intent(inout) :: history_
  double precision                                  , intent(  out) :: rateMassStellar, &
&  rateMassFuel, rateEnergyInput
  type            (abundances                      ), intent(inout) :: &
&  rateAbundancesFuel, rateAbundancesStellar
  type            (stellarLuminosities             ), intent(inout) :: &
&  rateLuminosityStellar
  logical                                           , intent(in   ) :: &
&  computeRateLuminosityStellar
 end subroutine myImplementationRates
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (stellarPopulationPropertiesClass), intent(inout) :: self
  integer                                  , intent(in   ) :: stateFile
```

```
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`historyCount` Return the number of stellar population property histories which must be stored. Must have the following interface:

```
integer function myImplementationHistoryCount(self)
 class(stellarPopulationPropertiesClass), intent(inout) :: self
end integer function myImplementationHistoryCount
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarPopulationPropertiesClass)                          , intent(inout) &
&  :: self
 type     (varying_string                 ), allocatable, dimension(:), intent(inout) &
&  :: allowedParameters
 character(len=*                          )                          , intent(in   ) &
&  :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarPopulationPropertiesClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`historyCreate` Create histories needed to store stellar population properties. Must have the following interface:

```
subroutine myImplementationHistoryCreate(self,node,history_)
 class(stellarPopulationPropertiesClass), intent(inout) :: self
 type (treeNode                        ), intent(inout) :: node
 type (history                         ), intent(inout) :: history_
end subroutine myImplementationHistoryCreate
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarPopulationPropertiesClass), intent(inout) :: self
 class(stellarPopulationPropertiesClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationPropertiesClass), intent(inout) :: self
 integer                                  , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`scales` Return scaling factors of stellar population properties for an ODE solver. Must have the following interface:

```
subroutine myImplementationScales(self,massStellar,abundancesStellar,history_)
 class           (stellarPopulationPropertiesClass), intent(inout) :: self
 double precision                                  , intent(in   ) :: massStellar
 type            (abundances                      ), intent(in   ) :: abundancesStellar
 type            (history                         ), intent(inout) :: history_
end subroutine myImplementationScales
```

Existing implementations are:

`stellarPopulationPropertiesNoninstantaneous` A stellar population properties class based on the noninstantaneous recycling approximation.

`stellarPopulationPropertiesInstantaneous` A stellar population properties class based on the instantaneous recycling approximation.

Stellar Population Selectors

Additional implementations for stellar population selectors are added using the `stellarPopulationSelector` class. The implementation should be placed in a file containing the directive:

```
!# <stellarPopulationSelector name="stellarPopulationSelectorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarPopulationSelector>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarPopulationSelectorMyImplementation`. The file *must* define a type that extends the `stellarPopulationSelectorClass` class (or extends another type which is itself an extension of the `stellarPopulationSelectorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarPopulationSelectorClass), intent(inout)           :: self
  logical                                , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (stellarPopulationSelectorClass), intent(inout)           :: self
 type   (inputParameters               ), intent(inout)           :: descriptor
 logical                                , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarPopulationSelectorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSelectorClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarPopulationSelectorClass)                          , intent(inout) ::&
&  self
 type     (varying_string               ), allocatable, dimension(:), intent(inout) ::&
&  allowedParameters
 character(len=*                         )                          , intent(in   ) ::&
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`isStarFormationRateDependent` Return true if the selection of stellar population is dependent on star formation rate. Must have the following interface:

```
logical function myImplementationIsStarFormationRateDependent(self)
 class(stellarPopulationSelectorClass), intent(inout) :: self
end logical function myImplementationIsStarFormationRateDependent
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarPopulationSelectorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarPopulationSelectorClass), intent(inout) :: self
 class(stellarPopulationSelectorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSelectorClass), intent(inout) :: self
 integer                                , intent(in   ) :: stateFile
 type   (fgsl_file                      ), intent(in   ) :: fgslStateFile
 integer(c_size_t                       ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`select` Return a stellar population. Must have the following interface:

```
class(stellarPopulationClass) function myImplementationSelect(self,rateStarFormation,&
&  abundances_,component)
 class           (stellarPopulationSelectorClass), intent(inout) :: self
 double precision                                , intent(in   ) :: rateStarFormation
 type            (abundances                     ), intent(in   ) :: abundances_
 class           (nodeComponent                  ), intent(in   ) :: component
end class(stellarPopulationClass) function myImplementationSelect
```

Existing implementations are:

`stellarPopulationSelectorDiskSpheroid` A stellar population selector class which returns a different population for disks and spheroids.

`stellarPopulationSelectorFixed` A fixed stellar population selector class.

Stellar Population Spectra

Additional implementations for stellar population spectra are added using the `stellarPopulationSpectra` class. The implementation should be placed in a file containing the directive:

```
!# <stellarPopulationSpectra name="stellarPopulationSpectraMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarPopulationSpectra>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarPopulationSpectraMyImplementation`. The file *must* define a type that extends the `stellarPopulationSpectraClass` class (or extends another type which is itself an extension of the `stellarPopulationSpectraClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (stellarPopulationSpectraClass), intent(inout)          :: self
 logical                               , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (stellarPopulationSpectraClass), intent(inout)          :: self
 type   (inputParameters              ), intent(inout)          :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`luminosity` Return the luminosity (in units of $L_\odot$ Hz^{-1}) for a stellar population, composition `abundances`, of the given `age` (in Gyr), at the specified `wavelength` (in Angstroms). Must have the following interface:

```
 double precision function myImplementationLuminosity(self,abundancesStellar,age        &
&        , wavelength,status)
  class           (stellarPopulationSpectraClass), intent(inout)           :: self
  type            (abundances                   ), intent(in   )           :: &
&  abundancesStellar
  double precision                                , intent(in   )           :: age, &
&  wavelength
  integer                                         , intent(  out), optional :: status
 end double precision function myImplementationLuminosity
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarPopulationSpectraClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSpectraClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`tabulation` Return a tabulation of ages and metallicities at which stellar spectra should be tabulated. Must have the following interface:

```
 subroutine myImplementationTabulation(self,agesCount, metallicitiesCount,ages     , &
&  metallicity)
  class           (stellarPopulationSpectraClass)                          , intent(&
&  inout) :: self
  integer                                                                  , intent(  &
&  out) :: agesCount, metallicitiesCount
  double precision                                , allocatable, dimension(:), intent(  &
&  out) :: ages, metallicity
 end subroutine myImplementationTabulation
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (stellarPopulationSpectraClass)                          , intent(inout) :: &
&  self
  type     (varying_string              ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
  character(len=*                       )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`wavelengths` Return a tabulation of wavelengths at which stellar spectra are defined. Must have the following interface:

```
 subroutine myImplementationWavelengths(self,wavelengthsCount,wavelengths)
  class           (stellarPopulationSpectraClass)                          , intent(&
&  inout) :: self
  integer                                                                  , intent(  &
&  out) :: wavelengthsCount
  double precision                                , allocatable, dimension(:), intent(  &
&  out) :: wavelengths
 end subroutine myImplementationWavelengths
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarPopulationSpectraClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarPopulationSpectraClass), intent(inout) :: self
 class(stellarPopulationSpectraClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`wavelengthInterval` At a given wavelength, return the wavelength interval in the tabulation of wavelength for which stellar spectra are defined. Must have the following interface:

```
double precision function myImplementationWavelengthInterval(self,wavelength)
 class           (stellarPopulationSpectraClass), intent(inout) :: self
 double precision                               , intent(in   ) :: wavelength
end double precision function myImplementationWavelengthInterval
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSpectraClass), intent(inout) :: self
 integer                               , intent(in   ) :: stateFile
 type   (fgsl_file                     ), intent(in   ) :: fgslStateFile
 integer(c_size_t                      ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarPopulationSpectraFile` Provides stellar population spectra via interpolation in a tabulation read from file. This should be an HDF5 file with the following structure:

```
ages                    Dataset {ageCount}
metallicities           Dataset {metallicityCount}
spectra                 Dataset {metallicityCount, ageCount, metallicityCount}
wavelengths             Dataset {wavelengthCount}
```

where the datasets contain the tabulated ages (in Gyr), metallicities (logarithmic, relative to Solar), wavelengths (in Å) and spectra (in $L_\odot$ Hz^{-1}). Currently, the following pre-computed stellar spectra files are available as a separate download from http://users.obs.carnegiescience.edu/abenson/galacticus/data/SSP_Data.tar.bz2:

`stellarPopulations/SSP_Spectra_Conroy-et-al_v2.0_imfSalpeter.hdf5` Corresponds to a Salpeter IMF computed using v2.0 of the FSPS code;

`stellarPopulations/SSP_Spectra_Conroy-et-al_v2.1_imfSalpeter.hdf5` Corresponds to a Salpeter IMF computed using v2.1 of the FSPS code;

`stellarPopulations/SSP_Spectra_Conroy-et-al_v2.1_imfChabrier.hdf5` Corresponds to a Chabrier IMF computed using v2.1 of the FSPS code;

`stellarPopulations/SSP_Spectra_Conroy-et-al_v2.2_imfChabrier.hdf5` Corresponds to a Chabrier IMF computed using v2.2 of the FSPS code;

`stellarPopulations/SSP_Spectra_Conroy-et-al_v2.2_imfKennicutt.hdf5` Corresponds to a Kennicutt IMF computed using v2.2 of the FSPS code;

`stellarPopulations/SSP_Spectra_Conroy-et-al_v2.2_imfBaugh2005TopHeavy.hdf5` Corresponds to the top-heavy IMF of Baugh et al. [2005] computed using v2.2 of the FSPS code;

`stellarPopulations/SSP_Spectra_Maraston_hbMorphologyRed_imfKroupa.hdf5` The spectra from Maraston [2005] for a Kroupa IMF and a red horizontal branch morphology;

`stellarPopulations/SSP_Spectra_Maraston_hbMorphologyRed_imfSalpeter.hdf5` The spectra from Maraston [2005] for a Salpeter IMF and a red horizontal branch morphology;

`stellarPopulations/SSP_Spectra_BC2003_highResolution_imfChabrier.hdf5` The (high resolution) spectra from Bruzual and Charlot [2003] for a Chabrier IMF, using Padova 1994 tracks;

`stellarPopulations/SSP_Spectra_BC2003_highResolution_imfSalpeter.hdf5` The (high resolution) spectra from Bruzual and Charlot [2003] for a Salpeter IMF, using Padova 1994 tracks;

`stellarPopulations/SSP_Spectra_BC2003_lowResolution_imfChabrier.hdf5` The (low resolution) spectra from Bruzual and Charlot [2003] for a Chabrier IMF, using Padova 1994 tracks;

`stellarPopulations/SSP_Spectra_BC2003_lowResolution_imfSalpeter.hdf5` The (low resolution) spectra from Bruzual and Charlot [2003] for a Salpeter IMF, using Padova 1994 tracks;

`stellarPopulations/SSP_Spectra_Grasil_gkn15rd_ken.hdf5` The spectra used by GRASIL for a Kennicutt IMF;

`stellarPopulations/SSP_Spectra_Grasil_gkn1rd_ken.hdf5` The spectra used by GRASIL for a Kennicutt IMF;

`stellarPopulations/SSP_Spectra_Grasil_gsrdk0b_sal.hdf5` The spectra used by GRASIL for a Salpeter IMF;

`stellarPopulations/SSP_Spectra_Grasil_imf27_kro.hdf5` Spectra used by GRASIL.

Note that the high resolution spectra from Bruzual and Charlot [2003] may require you to adjust the `[stellarPopulationLuminosityIntegrationToleranceRelative]` parameter to a larger value[7]. The sharp features in these high resolution spectra can be difficult to integrate. Scripts to convert the data provided by Maraston [2005] and Bruzual and Charlot [2003] into GALACTICUS's format are provided in the `scripts/ssps` folder.

`stellarPopulationSpectraFSPS` Provides stellar population spectra utilizing the FSPS package [Conroy et al., 2009]. If necessary, the `FSPS` code will be downloaded, patched and compiled and run to generate spectra. These tabulations are then stored to file for later re-use.

Postprocessors for stellar population spectra

Additional implementations for postprocessors for stellar population spectra are added using the `stellarPopulationSpectraP` class. The implementation should be placed in a file containing the directive:

```
!# <stellarPopulationSpectraPostprocessor name="stellarPopulationSpectraPostprocessorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarPopulationSpectraPostprocessor>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarPopulationSpectraPostprocessorMyImplementation`. The file *must* define a type that extends the `stellarPopulationSpectraPostprocessorClass` class (or extends another type which is itself an extension of the `stellarPopulationSpectraPostprocessorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarPopulationSpectraPostprocessorClass), intent(inout)          :: self
  logical                                            , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (stellarPopulationSpectraPostprocessorClass), intent(inout)          :: self
  type   (inputParameters                           ), intent(inout)          :: &
&  descriptor
  logical                                            , intent(in   ), optional :: &
&  includeMethod
 end subroutine myImplementationDescriptor
```

[7] Or, alternatively, set `[stellarPopulationLuminosityIntegrationToleranceDegrade]=true`. This will cause GALACTICUS to increase the tolerance as necessary to get the integrals to converge—issuing warnings each time the tolerance is increased.

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarPopulationSpectraPostprocessorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSpectraPostprocessorClass), intent(inout) :: self
 integer                                            , intent(in   ) :: stateFile
 type   (fgsl_file                                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarPopulationSpectraPostprocessorClass)                          , &
&  intent(inout) :: self
 type     (varying_string                            ), allocatable, dimension(:), &
&  intent(inout) :: allowedParameters
 character(len=*                                     )                          , &
&  intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarPopulationSpectraPostprocessorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarPopulationSpectraPostprocessorClass), intent(inout) :: self
 class(stellarPopulationSpectraPostprocessorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSpectraPostprocessorClass), intent(inout) :: self
 integer                                            , intent(in   ) :: stateFile
 type   (fgsl_file                                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`multiplier` Return the multiplicative modification to the spectrum. Must have the following interface:

```
double precision function myImplementationMultiplier(self,wavelength, age, redshift)
 class           (stellarPopulationSpectraPostprocessorClass), intent(inout) :: self
 double precision                                            , intent(in   ) :: &
&  wavelength, age, redshift
 end double precision function myImplementationMultiplier
```

Existing implementations are:

`stellarPopulationSpectraPostprocessorMeiksin2006` Multiplier the Meiksin [2006] calculation of the attenuation of spectra by the intergalactic medium.

`stellarPopulationSpectraPostprocessorInoue2014` Apply the Inoue et al. [2014] calculation of the attenuation of spectra by the intergalactic medium.

`stellarPopulationSpectraPostprocessorUnescaped` Retains only unescaped stellar populations.

`stellarPopulationSpectraPostprocessorIdentity` Performs an indentity postprocessing of spectra.

`stellarPopulationSpectraPostprocessorMadau1995` Multiplier the Madau [1995] calculation of the attenuation of spectra by the intergalactic medium.

`stellarPopulationSpectraPostprocessorRecent` Retains only recent stellar populations.

`stellarPopulationSpectraPostprocessorLycSuppress` A stellar population spectrum postprocessor which completely supresses the Lyman continuum.

`stellarPopulationSpectraPostprocessorSequence` A sequence stellar population spectra postprocessor class.

Builder for postprocessors for stellar population spectra

Additional implementations for builder for postprocessors for stellar population spectra are added using the `stellarPopulationSpectraPostprocessorBuilder` class. The implementation should be placed in a file containing the directive:

```
!# <stellarPopulationSpectraPostprocessorBuilder name="stellarPopulationSpectraPostprocessorBuilderMyImp
!# <description>A short description of the implementation.</description>
!# </stellarPopulationSpectraPostprocessorBuilder>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarPopulationSpectraPostprocessorBuilderMyImplementation`. The file *must* define a type that extends the `stellarPopulationSpectraPostprocessorBuilderClass` class (or extends another type which is itself an extension of the `stellarPopulationSpectraPostprocessorBuilderClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarPopulationSpectraPostprocessorBuilderClass), intent(inout)          ::&
&   self
  logical                                                   , intent(in   ), optional ::&
&   includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (stellarPopulationSpectraPostprocessorBuilderClass), intent(inout)          ::&
&   self
  type   (inputParameters                                  ), intent(inout)          ::&
&   descriptor
  logical                                                   , intent(in   ), optional ::&
&   includeMethod
 end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAutoHook(self)
  class(stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: self
 end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
  class  (stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: self
  integer                                                   , intent(in   ) :: stateFile
  type   (fgsl_file                                        ), intent(in   ) :: &
&  fgslStateFile
  integer(c_size_t                                         ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (stellarPopulationSpectraPostprocessorBuilderClass)                       &
&   , intent(inout) :: self
  type     (varying_string                                    ), allocatable, dimension&
&  (:), intent(inout) :: allowedParameters
  character(len=*                                             )                       &
&   , intent(in   ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`build` Build and return a postprocessor. Must have the following interface:

```
 class(stellarPopulationSpectraPostprocessorClass) function myImplementationBuild(self,&
&  descriptor)
  class(stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: self
  type (varying_string                                   ), intent(in   ) :: descriptor
 end class(stellarPopulationSpectraPostprocessorClass) function myImplementationBuild
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: self
 class(stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarPopulationSpectraPostprocessorBuilderClass), intent(inout) :: self
 integer                                                   , intent(in   ) :: stateFile
 type   (fgsl_file                                        ), intent(in   ) :: &
&  fgslStateFile
 integer(c_size_t                                         ), intent(in   ) :: &
&  stateOperationID
 end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarPopulationSpectraPostprocessorBuilderLookup` A stellar population spectra postprocessor builder which simply looks up postprocessors by name.

Stellar Spectra Dust Attenuation

Additional implementations for stellar spectra dust attenuation are added using the `stellarSpectraDustAttenuation` class. The implementation should be placed in a file containing the directive:

```
!# <stellarSpectraDustAttenuation name="stellarSpectraDustAttenuationMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarSpectraDustAttenuation>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarSpectraDustAttenuationMyImplementation`. The file *must* define a type that extends the `stellarSpectraDustAttenuationClass` class (or extends another type which is itself an extension of the `stellarSpectraDustAttenuationClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`isSeparable` Return true if the attenuation is separable into a product of functions of wavelength, age, and V-band attenuation. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationIsSeparable(self)
 class(stellarSpectraDustAttenuationClass), intent(inout) :: self
end logical function myImplementationIsSeparable
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarSpectraDustAttenuationClass), intent(inout)           :: self
  logical                                    , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (stellarSpectraDustAttenuationClass), intent(inout)           :: self
 type   (inputParameters                   ), intent(inout)           :: descriptor
 logical                                    , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarSpectraDustAttenuationClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarSpectraDustAttenuationClass), intent(inout) :: self
 integer                                    , intent(in   ) :: stateFile
 type   (fgsl_file                         ), intent(in   ) :: fgslStateFile
 integer(c_size_t                          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarSpectraDustAttenuationClass)                          , intent(inout&
&  ) :: self
 type     (varying_string                    ), allocatable, dimension(:), intent(inout&
&  ) :: allowedParameters
 character(len=*                             )                          , intent(in   &
&  ) :: sourceName
 end subroutine myImplementationAllowedParameters
```

`attenuation` Return the attenuation, in magnitudes, of stellar spectra due to dust at the given wavelength, age, and V-band extinction. Must have the following interface:

```
 double precision function myImplementationAttenuation(self,wavelength, age, &
&  vBandAttenuation)
  class           (stellarSpectraDustAttenuationClass), intent(inout) :: self
  double precision                                    , intent(in   ) :: wavelength, age&
&  , vBandAttenuation
 end double precision function myImplementationAttenuation
```

`isAgeDependent` Return true if the attenuation may depend on the age of the stellar population. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationIsAgeDependent(self)
 class(stellarSpectraDustAttenuationClass), intent(inout) :: self
end logical function myImplementationIsAgeDependent
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarSpectraDustAttenuationClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarSpectraDustAttenuationClass), intent(inout) :: self
 class(stellarSpectraDustAttenuationClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarSpectraDustAttenuationClass), intent(inout) :: self
 integer                                    , intent(in   ) :: stateFile
 type   (fgsl_file                          ), intent(in   ) :: fgslStateFile
 integer(c_size_t                           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarSpectraDustAttenuationGordon2003` Returns the dust attenuation of stellar spectra according to the model of Gordon et al. [2003].

`stellarSpectraDustAttenuationTabulated` Returns the dust attenuation of stellar spectra from a tabulated relation.

`stellarSpectraDustAttenuationCharlotFall2000` Returns the dust attenuation of stellar spectra according to the model of Charlot and Fall [2000].

`stellarSpectraDustAttenuationWittGordon2000` Returns the dust attenuation of stellar spectra according to the model of Witt and Gordon [2000].

`stellarSpectraDustAttenuationZero` Returns a zero dust attenuation.

`stellarSpectraDustAttenuationCardelli1989` Returns the dust attenuation of stellar spectra according to the model of Cardelli et al. [1989].

`stellarSpectraDustAttenuationCalzetti2000` Returns the dust attenuation of stellar spectra according to the model of Calzetti et al. [2000].

`stellarSpectraDustAttenuationPrevotBouchet` Returns the dust attenuation of stellar spectra according to the model of Prevot et al. [1984] and Bouchet et al. [1985].

Stellar Tracks

Additional implementations for stellar tracks are added using the `stellarTracks` class. The implementation should be placed in a file containing the directive:

```
!# <stellarTracks name="stellarTracksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarTracks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarTracksMyImplementation`. The file *must* define a type that extends the `stellarTracksClass` class (or extends another type which is itself an extension of the `stellarTracksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`temperatureEffective` Returns the effective temperature of a star of given `initialMass`, `metallicity` and `age`. Must have the following interface:

```
 double precision function myImplementationTemperatureEffective(self,initialMass, &
&  metallicity, age)
  class           (stellarTracksClass), intent(inout) :: self
  double precision                    , intent(in   ) :: initialMass, metallicity, age
 end double precision function myImplementationTemperatureEffective
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarTracksClass), intent(inout)           :: self
  logical                    , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (stellarTracksClass), intent(inout)           :: self
  type   (inputParameters   ), intent(inout)           :: descriptor
  logical                    , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`luminosity` Returns the bolometric luminosity of a star of given `initialMass`, `metallicity` and `age`. Must have the following interface:

```
double precision function myImplementationLuminosity(self,initialMass, metallicity, age&
&  )
 class           (stellarTracksClass), intent(inout) :: self
 double precision                    , intent(in   ) :: initialMass, metallicity, age
end double precision function myImplementationLuminosity
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarTracksClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarTracksClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarTracksClass)                          , intent(inout) :: self
 type     (varying_string    ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*             )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarTracksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarTracksClass), intent(inout) :: self
 class(stellarTracksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarTracksClass), intent(inout) :: self
 integer                    , intent(in   ) :: stateFile
 type   (fgsl_file         ), intent(in   ) :: fgslStateFile
 integer(c_size_t          ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarTracksFile` A stellar tracks class in which the tracks are read from file and interpolated.

Stellar Winds

Additional implementations for stellar winds are added using the `stellarWinds` class. The implementation should be placed in a file containing the directive:

```
!# <stellarWinds name="stellarWindsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </stellarWinds>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `stellarWindsMyImplementation`. The file *must* define a type that extends the `stellarWindsClass` class (or extends another type which is itself an extension of the `stellarWindsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`velocityTerminal` Return the terminal velocity (in km/s) of winds from stars of given `initialMass`, `age` and `metallicity`. Must have the following interface:

```
 double precision function myImplementationVelocityTerminal(self,initialMass, age, &
&  metallicity)
  class           (stellarWindsClass), intent(inout) :: self
  double precision                   , intent(in   ) :: initialMass, age, metallicity
 end double precision function myImplementationVelocityTerminal
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (stellarWindsClass), intent(inout)           :: self
  logical                   , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (stellarWindsClass), intent(inout)           :: self
  type   (inputParameters  ), intent(inout)           :: descriptor
  logical                   , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`rateMassLoss` Return the mass loss rate (in $M_\odot$/Gyr) from stars of given `initialMass`, `age` and `metallicity`. Must have the following interface:

```
double precision function myImplementationRateMassLoss(self,initialMass, age, &
&  metallicity)
 class           (stellarWindsClass), intent(inout) :: self
 double precision                   , intent(in   ) :: initialMass, age, metallicity
end double precision function myImplementationRateMassLoss
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(stellarWindsClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarWindsClass), intent(inout) :: self
 integer                   , intent(in   ) :: stateFile
 type   (fgsl_file        ), intent(in   ) :: fgslStateFile
 integer(c_size_t         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (stellarWindsClass)                          , intent(inout) :: self
 type     (varying_string   ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*            )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(stellarWindsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(stellarWindsClass), intent(inout) :: self
 class(stellarWindsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (stellarWindsClass), intent(inout) :: self
 integer                   , intent(in   ) :: stateFile
 type   (fgsl_file        ), intent(in   ) :: fgslStateFile
 integer(c_size_t         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`stellarWindsLeitherer1992` A stellar winds class based on Leitherer et al. [1992].

Supernovae Type Ia

Additional implementations for supernovae type ia are added using the `supernovaePopulationIII` class. The implementation should be placed in a file containing the directive:

```
!# <supernovaePopulationIII name="supernovaePopulationIIIMyImplementation">
!# <description>A short description of the implementation.</description>
!# </supernovaePopulationIII>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `supernovaePopulationIIIMyImplementation`. The file *must* define a type that extends the `supernovaePopulationIIIClass` class (or extends another type which is itself an extension of the `supernovaePopulationIIIClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (supernovaePopulationIIIClass), intent(inout)           :: self
 logical                              , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (supernovaePopulationIIIClass), intent(inout)           :: self
 type   (inputParameters             ), intent(inout)           :: descriptor
 logical                              , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(supernovaePopulationIIIClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (supernovaePopulationIIIClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                   ), intent(in   ) :: fgslStateFile
 integer(c_size_t                    ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (supernovaePopulationIIIClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(supernovaePopulationIIIClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(supernovaePopulationIIIClass), intent(inout) :: self
 class(supernovaePopulationIIIClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (supernovaePopulationIIIClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                   ), intent(in   ) :: fgslStateFile
 integer(c_size_t                    ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`energyCumulative` Return the cumulative energy input from Population III supernovae from stars of given `initialMass`, `age` and `metallicity`. Must have the following interface:

```
double precision function myImplementationEnergyCumulative(self,initialMass, age, &
&  metallicity)
 class           (supernovaePopulationIIIClass), intent(inout) :: self
 double precision                              , intent(in   ) :: initialMass, age, &
&  metallicity
 end double precision function myImplementationEnergyCumulative
```

Existing implementations are:

`supernovaePopulationIIIHegerWoosley2002` A Population III supernovae class based on Heger and Woosley [2002].

Supernovae Type Ia

Additional implementations for supernovae type ia are added using the `supernovaeTypeIa` class. The implementation should be placed in a file containing the directive:

```
!# <supernovaeTypeIa name="supernovaeTypeIaMyImplementation">
!# <description>A short description of the implementation.</description>
!# </supernovaeTypeIa>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `supernovaeTypeIaMyImplementation`. The file *must* define a type that extends the `supernovaeTypeIaClass` class (or extends another type which is itself an extension of the `supernovaeTypeIaClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (supernovaeTypeIaClass), intent(inout)           :: self
  logical                       , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDescriptor(self,descriptor,includeMethod)
  class  (supernovaeTypeIaClass), intent(inout)           :: self
  type   (inputParameters      ), intent(inout)           :: descriptor
  logical                       , intent(in   ), optional :: includeMethod
 end subroutine myImplementationDescriptor
```

`number` Return the cumulative number of Type Ia supernovae from a stellar population of the given `initialMass`, `age`, and `metallicity`. Must have the following interface:

```
 double precision function myImplementationNumber(self,initialMass, age, metallicity)
  class           (supernovaeTypeIaClass), intent(inout) :: self
  double precision                       , intent(in   ) :: initialMass, age, &
&  metallicity
 end double precision function myImplementationNumber
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(supernovaeTypeIaClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (supernovaeTypeIaClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (supernovaeTypeIaClass)                            , intent(inout) :: self
 type     (varying_string       ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                )                            , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`yield` Return the cumulative yield from Type Ia supernoave from a stellar population of the given `initialMass`, `age`, and `metallicity`. Must have the following interface:

```
double precision function myImplementationYield(self,initialMass, age, metallicity,&
&  atomIndex)
 class           (supernovaeTypeIaClass), intent(inout)           :: self
 double precision                       , intent(in   )           :: initialMass, age, &
&  metallicity
 integer                                , intent(in   ), optional :: atomIndex
end double precision function myImplementationYield
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(supernovaeTypeIaClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(supernovaeTypeIaClass), intent(inout) :: self
 class(supernovaeTypeIaClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (supernovaeTypeIaClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`supernovaeTypeIaNagashima2005` A supernovae type Ia class based on Nagashima et al. [2005].

Survey Geometry

Additional implementations for survey geometry are added using the `surveyGeometry` class. The implementation should be placed in a file containing the directive:

```
!# <surveyGeometry name="surveyGeometryMyImplementation">
!# <description>A short description of the implementation.</description>
!# </surveyGeometry>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `surveyGeometryMyImplementation`. The file *must* define a type that extends the `surveyGeometryClass` class (or extends another type which is itself an extension of the `surveyGeometryClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`windowFunctionAvailable` Returns true if survey 3-D window functions are available. Must have the following interface:

```
logical function myImplementationWindowFunctionAvailable(self)
 class(surveyGeometryClass), intent(inout) :: self
end logical function myImplementationWindowFunctionAvailable
```

`angularPower` Return C_ℓ^{ij}, where $(2\ell+1)C_\ell^{ij} = \sum_{m=-\ell}^{+\ell} \Psi_{\ell m}^i \Psi_{\ell m}^{j*}$, and $\Psi_{\ell m}^i$ are the cofficients of the spherical harmonic expansion of the $i^{\rm th}$ field. Must have the following interface:

```
double precision function myImplementationAngularPower(self,i,j,l)
 class  (surveyGeometryClass), intent(inout) :: self
 integer                     , intent(in   ) :: i, j, l
end double precision function myImplementationAngularPower
```

`angularPowerMaximumDegree` Return the maximum degree, $\ell_{\rm max}$, for which the angular power is available. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationAngularPowerMaximumDegree(self)
 class(surveyGeometryClass), intent(inout) :: self
end integer function myImplementationAngularPowerMaximumDegree
```

`volumeMaximum` Returns the maximum volume (in Mpc^3) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationVolumeMaximum(self,mass,field)
 class           (surveyGeometryClass), intent(inout)           :: self
 double precision                     , intent(in   )           :: mass
 integer                              , intent(in   ), optional :: field
end double precision function myImplementationVolumeMaximum
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(surveyGeometryClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`pointIncluded` Return true if the given Cartesian point lies within the survey bounds for the given mass limit. Must have the following interface:

```
logical function myImplementationPointIncluded(self,point,mass)
 class           (surveyGeometryClass)              , intent(inout) :: self
 double precision                     , dimension(3), intent(in   ) :: point
 double precision                                    , intent(in   ) :: mass
end logical function myImplementationPointIncluded
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (surveyGeometryClass), intent(inout)           :: self
 type   (inputParameters    ), intent(inout)           :: descriptor
 logical                     , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (surveyGeometryClass), intent(inout)           :: self
 logical                     , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(surveyGeometryClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (surveyGeometryClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
```

```
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`fieldCount` Returns the number of distinct fields included in the survey. A default implementation exists. If overridden the following interface must be used:

```
integer function myImplementationFieldCount(self)
 class(surveyGeometryClass), intent(inout) :: self
end integer function myImplementationFieldCount
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (surveyGeometryClass)                          , intent(inout) :: self
 type     (varying_string     ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*              )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`solidAngle` Return the solid angle (in steradians) of the survey. Must have the following interface:

```
double precision function myImplementationSolidAngle(self,field)
 class  (surveyGeometryClass), intent(inout)           :: self
 integer                     , intent(in   ), optional :: field
end double precision function myImplementationSolidAngle
```

`distanceMaximum` Returns the maximum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) could be detected. Must have the following interface:

```
 double precision function myImplementationDistanceMaximum(self,mass , magnitudeAbsolute&
&  , luminosity,field)
  class           (surveyGeometryClass), intent(inout)           :: self
  double precision                     , intent(in   ), optional :: mass, &
&  magnitudeAbsolute, luminosity
  integer                              , intent(in   ), optional :: field
 end double precision function myImplementationDistanceMaximum
```

`windowFunctions` Returns the window functions on a grid of the specified size (`gridCount` cells in each dimension) for galaxies of the specified `mass1` and `mass2` (in $M_\odot$). The `boxLength` should be set to an appropriate value to fully enclose (with sufficient buffering to allow for Fourier transformation) the two window functions. Must have the following interface:

```
 subroutine myImplementationWindowFunctions(self,mass1          , mass2,gridCount,&
&  boxLength,windowFunction1, windowFunction2)
  class           (surveyGeometryClass)                                    , &
&  intent(inout) :: self
  double precision                                                         , &
&  intent(in   ) :: mass1, mass2
  integer                                                                  , &
&  intent(in   ) :: gridCount
  double precision                                                         , &
&  intent(  out) :: boxLength
```

```
  complex         (c_double_complex   ), dimension(gridcount,gridcount,gridcount), &
& intent(  out) :: windowFunction1, windowFunction2
 end subroutine myImplementationWindowFunctions
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(surveyGeometryClass), intent(inout) :: self
 class(surveyGeometryClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (surveyGeometryClass), intent(inout) :: self
 integer                     , intent(in   ) :: stateFile
 type   (fgsl_file          ), intent(in   ) :: fgslStateFile
 integer(c_size_t           ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

`distanceMinimum` Returns the minimum distance (in Mpc) at which a galaxy of the specified `mass` (in $M_\odot$) would be included in the survey. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationDistanceMinimum(self,mass , magnitudeAbsolute&
&  , luminosity,field)
  class           (surveyGeometryClass), intent(inout)           :: self
  double precision                     , intent(in   ), optional :: mass, &
& magnitudeAbsolute, luminosity
  integer                              , intent(in   ), optional :: field
end double precision function myImplementationDistanceMinimum
```

`angularPowerAvailable` Returns true if angular power spectrum of survey window function is available. Must have the following interface:

```
logical function myImplementationAngularPowerAvailable(self)
 class(surveyGeometryClass), intent(inout) :: self
end logical function myImplementationAngularPowerAvailable
```

Existing implementations are:

`surveyGeometryRandomPoints` Implements survey geometries defined by random points.

`surveyGeometryLocalGroupClassical` Implements a geometry corresponding to the detectability of classical Local Group galaxies.

`surveyGeometryFullSky` Implements survey geometries over the full sky.

`surveyGeometryKelvin2014GAMAnear` Implements the geometry of the GAMAnear survey of Kelvin et al. [2014].

`surveyGeometryGunawardhana2013SDSS` Implements the geometry of the SDSS survey of Gunawardhana et al. [2013].

`surveyGeometryMonteroDorta2009SDSS` Implements the geometry of the SDSS survey of Montero-Dorta and Prada [2009].

`surveyGeometryBernardi2013SDSS` Implements the geometry of the SDSS survey of Bernardi et al. [2013]. See §12.59.2.

`surveyGeometryCaputi2011UKIDSSUDS` Implements the survey geometry of the SDSS sample used by Caputi et al. [2011]. See §12.59.9.

`surveyGeometryCombined` Implements a survey geometry which combines multiple other surveys.

`surveyGeometryMoustakas2013PRIMUS` Implements the geometry of the PRIMUS survey of Moustakas et al. [2013]. See §12.59.6.

`surveyGeometryBaldry2012GAMA` Implements the geometry of the GAMA survey of Baldry et al. [2012]. See §12.59.5.

`surveyGeometryLiWhite2009SDSS` Implements the survey geometry of the SDSS sample used by Li and White [2009]. See §12.59.1.

`surveyGeometryLocalGroupDES` Implements the geometry of the DES survey for Local Group dwarfs.

`surveyGeometryHearin2014SDSS` Implements the survey geometry of the SDSS sample used by Hearin et al. [2013].

`surveyGeometryDavidzon2013VIPERS` Implements the geometry of the VIPERS survey of Davidzon et al. [2013]. See §12.59.3.

`surveyGeometryMangle` Implements an abstract survey geometry using MANGLE polygons.

`surveyGeometryMartin2010ALFALFA` Implements the survey geometry of the SDSS sample used by Martin et al. [2010]. See §12.59.8.

`surveyGeometryTomczak2014ZFOURGE` Implements the geometry of the ZFOURGE survey of Tomczak et al. [2014]. See §12.59.4.

`surveyGeometryMuzzin2013ULTRAVISTA` Implements the geometry of the ULTRAVISTA survey of Muzzin et al. [2013].

`surveyGeometryLocalGroupSDSS` Implements the geometry of the SDSS survey with a depth for Local Group dwarf detection.

Tasks

Additional implementations for tasks are added using the `task` class. The implementation should be placed in a file containing the directive:

```
!# <task name="taskMyImplementation">
!# <description>A short description of the implementation.</description>
!# </task>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `taskMyImplementation`. The file *must* define a type that extends the `taskClass` class (or extends another type

which is itself an extension of the `taskClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (taskClass), intent(inout)           :: self
 logical           , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (taskClass      ), intent(inout)           :: self
 type   (inputParameters), intent(inout)           :: descriptor
 logical                 , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(taskClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`perform` Perform the task. Must have the following interface:

```
subroutine myImplementationPerform(self,status)
 class  (taskClass), intent(inout)           :: self
 integer           , intent(  out), optional :: status
end subroutine myImplementationPerform
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (taskClass), intent(inout) :: self
 integer           , intent(in   ) :: stateFile
 type   (fgsl_file), intent(in   ) :: fgslStateFile
 integer(c_size_t ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (taskClass     )                            , intent(inout) :: self
 type     (varying_string), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*         )                            , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`requiresOutputFile` Should return true if the task requires the main output file to be open. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationRequiresOutputFile(self)
 class(taskClass), intent(inout) :: self
end logical function myImplementationRequiresOutputFile
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(taskClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(taskClass), intent(inout) :: self
 class(taskClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (taskClass), intent(inout) :: self
 integer           , intent(in   ) :: stateFile
 type   (fgsl_file), intent(in   ) :: fgslStateFile
 integer(c_size_t ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`taskPosteriorSample` A task which performs sampling from a posterior distribution.

`taskBuildToolFSPS` A task which builds the FSPS tool.

`taskLocalGroupDatabase` A task which updates the Local Group database.

`taskExcursionSets` A task which computes and outputs the halo mass function and related quantities.

`taskBuildToolCloudy` A task which builds the Cloudy tool.

`taskEvolveForests` A task which evolves galaxies within a set of merger tree forests.

`taskConditionalMassFunction` A task which computes the conditional mass function in bins of mass for a fixed halo mass.

`taskMassFunctionCovariance` A task which computes and stores covariance matrices for mass functions.

`taskAGNSpectraHopkins2008BuildFile` A task which evolves galaxies within a set of merger tree forests.

`taskHaloModelProjectedCorrelationFunction` A task which generates a mock catalog of galaxies based on a simple halo model approach.

`taskCatalogProjectedCorrelationFunction` A task which computes projected correlation functions based on a simple halo model approach.

`taskMergerTreeFileBuilder` A task which computes and outputs the halo mass function and related quantities.

`taskNBodyAnalyze` A task which analyzes N-body simulation data.

`taskReport` A task which reports on version and build information.

`taskHaloMassFunction` A task which computes and outputs the halo mass function and related quantities.

`taskPowerSpectra` A task which computes and outputs the power spectrum and related quantities.

`taskIntergalacticMediumState` A task which outputs the state of the intergalactic medium.

`taskHaloModelGenerate` A task which generates a mock catalog of galaxies based on a simple halo model approach.

`taskBuildToolCAMB` A task which builds the CAMB tool.

`taskBuildToolRecFast` A task which builds the RecFast tool.

`taskHaloSpinDistribution` A task which computes and outputs the halo spin distribution.

`taskMulti` A task which performs multiple other tasks.

Tidal stripping in disks

Additional implementations for tidal stripping in disks are added using the `tidalStrippingDisks` class. The implementation should be placed in a file containing the directive:

```
!# <tidalStrippingDisks name="tidalStrippingDisksMyImplementation">
!# <description>A short description of the implementation.</description>
!# </tidalStrippingDisks>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `tidalStrippingDisksMyImplementation`. The file *must* define a type that extends the `tidalStrippingDisksClass` class (or extends another type which is itself an extension of the `tidalStrippingDisksClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (tidalStrippingDisksClass), intent(inout)          :: self
  logical                          , intent(in   ), optional :: includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (tidalStrippingDisksClass), intent(inout)           :: self
 type   (inputParameters         ), intent(inout)           :: descriptor
 logical                          , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`rateMassLoss` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the disk component of `node`. Must have the following interface:

```
double precision function myImplementationRateMassLoss(self,node)
 class(tidalStrippingDisksClass), intent(inout) :: self
 type (treeNode                ), intent(inout) :: node
end double precision function myImplementationRateMassLoss
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(tidalStrippingDisksClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (tidalStrippingDisksClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file                ), intent(in   ) :: fgslStateFile
 integer(c_size_t                 ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (tidalStrippingDisksClass)                              , intent(inout) :: self
 type     (varying_string          ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                   )                              , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(tidalStrippingDisksClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(tidalStrippingDisksClass), intent(inout) :: self
 class(tidalStrippingDisksClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (tidalStrippingDisksClass), intent(inout) :: self
 integer                          , intent(in   ) :: stateFile
 type   (fgsl_file               ), intent(in   ) :: fgslStateFile
 integer(c_size_t                ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`tidalStrippingDisksNull` A null model of tidal stripping in galactic disks.

`tidalStrippingDisksSimple` A simple model of tidal stripping in galactic disks.

Tidal stripping in spheroids

Additional implementations for tidal stripping in spheroids are added using the `tidalStrippingSpheroids` class. The implementation should be placed in a file containing the directive:

```
!# <tidalStrippingSpheroids name="tidalStrippingSpheroidsMyImplementation">
!# <description>A short description of the implementation.</description>
!# </tidalStrippingSpheroids>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `tidalStrippingSpheroidsMyImplementation`. The file *must* define a type that extends the `tidalStrippingSpheroidsClass` class (or extends another type which is itself an extension of the `tidalStrippingSpheroidsClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (tidalStrippingSpheroidsClass), intent(inout)           :: self
 logical                              , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (tidalStrippingSpheroidsClass), intent(inout)           :: self
 type   (inputParameters             ), intent(inout)           :: descriptor
 logical                               , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`rateMassLoss` Returns the rate of mass loss (in $M_\odot$ Gyr^{-1}) due to tidal stripping of the spheroid component of `node`. Must have the following interface:

```
double precision function myImplementationRateMassLoss(self,node)
 class(tidalStrippingSpheroidsClass), intent(inout) :: self
 type (treeNode                    ), intent(inout) :: node
end double precision function myImplementationRateMassLoss
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(tidalStrippingSpheroidsClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (tidalStrippingSpheroidsClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (tidalStrippingSpheroidsClass)                          , intent(inout) :: &
&  self
 type     (varying_string             ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                      )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(tidalStrippingSpheroidsClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(tidalStrippingSpheroidsClass), intent(inout) :: self
 class(tidalStrippingSpheroidsClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (tidalStrippingSpheroidsClass), intent(inout) :: self
 integer                              , intent(in   ) :: stateFile
 type   (fgsl_file                    ), intent(in   ) :: fgslStateFile
 integer(c_size_t                     ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`tidalStrippingSpheroidsNull` A null model of tidal stripping in galactic spheroids.

`tidalStrippingSpheroidsSimple` A simple model of tidal stripping in galactic spheroids.

Transfer Function

Additional implementations for transfer function are added using the `transferFunction` class. The implementation should be placed in a file containing the directive:

```
!# <transferFunction name="transferFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </transferFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `transferFunctionMyImplementation`. The file *must* define a type that extends the `transferFunctionClass` class (or extends another type which is itself an extension of the `transferFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (transferFunctionClass), intent(inout)           :: self
 logical                       , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (transferFunctionClass), intent(inout)           :: self
 type   (inputParameters      ), intent(inout)           :: descriptor
 logical                       , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(transferFunctionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`value` Return the transfer function for $k =$`wavenumber` [Mpc^{-1}]. Must have the following interface:

```
double precision function myImplementationValue(self,wavenumber)
 class           (transferFunctionClass), intent(inout) :: self
 double precision                       , intent(in   ) :: wavenumber
end double precision function myImplementationValue
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (transferFunctionClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`logarithmicDerivative` Return the logarithmic derivative of the transfer function for $k =$`wavenumber` [Mpc^{-1}]. Must have the following interface:

```
double precision function myImplementationLogarithmicDerivative(self,wavenumber)
 class           (transferFunctionClass), intent(inout) :: self
 double precision                       , intent(in   ) :: wavenumber
end double precision function myImplementationLogarithmicDerivative
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (transferFunctionClass)                          , intent(inout) :: self
 type     (varying_string       ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                          , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`halfModeMass` Return the mass (in $M_\odot$) corresponding to the wavenumber at which the transfer function is suppressed by a factor of two due to small-scale dark matter particle physics. Must have the following interface:

```
double precision function myImplementationHalfModeMass(self,status)
 class  (transferFunctionClass), intent(inout)           :: self
 integer                       , intent(  out), optional :: status
end double precision function myImplementationHalfModeMass
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(transferFunctionClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(transferFunctionClass), intent(inout) :: self
 class(transferFunctionClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`epochTime` Return the cosmic time corresponding to the epoch for which this transfer function is defined. Must have the following interface:

```
double precision function myImplementationEpochTime(self)
 class(transferFunctionClass), intent(inout) :: self
end double precision function myImplementationEpochTime
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (transferFunctionClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file             ), intent(in   ) :: fgslStateFile
 integer(c_size_t              ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`transferFunctionAccelerator` A transfer function class which accelerates calculations of another transfer function class by tabulation for rapid interpolation.

`transferFunctionEisensteinHu1999` Provides the Eisenstein and Hu [1999] fitting function to the transfer function. The effective number of neutrino species and the summed mass (in electron volts) of all neutrino species are specified via the `neutrinoNumberEffective` and `neutrinoMassSummed` parameters respectively.

`transferFunctionCAMB` Provides a transfer function class in which the transfer function is generated by CAMB using the specified cosmological parameters. The transfer function is written out to a file in the `data/` directory and will be re-read later if needed.

`transferFunctionBode2001` Provides a transfer function based on the thermal WDM modifier of Bode et al. [2001].

`transferFunctionBBKSWDM` Provides a transfer function based on the WDM modifier of Bardeen et al. [1986].

`transferFunctionFile` Provides a transfer function from a tabulation given in an HDF5 file with the following structure:

```
HDF5 "transferFunction.hdf5" {
GROUP "/" {
ATTRIBUTE "description" {
DATATYPE  H5T_STRING {

DATASPACE  SIMPLE { ( 1000 ) / ( 1000 ) }
}
}
}
```

`transferFunctionIdentity` Provides an identity transfer function.

`transferFunctionBBKS` Provides the Bardeen et al. [1986] fitting function for the transfer function.

Unevolved Subhalo Mass Function

Additional implementations for unevolved subhalo mass function are added using the `unevolvedSubhaloMassFunction` class. The implementation should be placed in a file containing the directive:

```
!# <unevolvedSubhaloMassFunction name="unevolvedSubhaloMassFunctionMyImplementation">
!# <description>A short description of the implementation.</description>
!# </unevolvedSubhaloMassFunction>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `unevolvedSubhaloMassFunctionMyImplementation`. The file *must* define a type that extends the `unevolvedSubhaloMassFunctionClass` class (or extends another type which is itself an extension of the `unevolvedSubhaloMassFunctionClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
  class  (unevolvedSubhaloMassFunctionClass), intent(inout)          :: self
  logical                                   , intent(in   ), optional :: &
&  includeSourceDigest
 end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (unevolvedSubhaloMassFunctionClass), intent(inout)          :: self
 type   (inputParameters                  ), intent(inout)          :: descriptor
 logical                                   , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(unevolvedSubhaloMassFunctionClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (unevolvedSubhaloMassFunctionClass), intent(inout) :: self
 integer                                   , intent(in   ) :: stateFile
 type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
 integer(c_size_t                         ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`integrated` Return the unevolved subhalo mass function per host at `time` [Gyr] in hosts of mass `massHost` [$M_\odot$] integrated between `massLow` and `massHigh` [$M_\odot$]. Must have the following interface:

```
 double precision function myImplementationIntegrated(self,time, massLow, massHigh, &
&  massHost)
  class           (unevolvedSubhaloMassFunctionClass), intent(inout) :: self
  double precision                                   , intent(in   ) :: time, massLow, &
&  massHigh, massHost
 end double precision function myImplementationIntegrated
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
  class    (unevolvedSubhaloMassFunctionClass)                          , intent(inout)&
&   :: self
  type     (varying_string                  ), allocatable, dimension(:), intent(inout)&
&   :: allowedParameters
  character(len=*                           )                          , intent(in   )&
&   :: sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(unevolvedSubhaloMassFunctionClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(unevolvedSubhaloMassFunctionClass), intent(inout) :: self
  class(unevolvedSubhaloMassFunctionClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
  class  (unevolvedSubhaloMassFunctionClass), intent(inout) :: self
  integer                                   , intent(in   ) :: stateFile
  type   (fgsl_file                        ), intent(in   ) :: fgslStateFile
  integer(c_size_t                         ), intent(in   ) :: stateOperationID
 end subroutine myImplementationStateRestore
```

`differential` Return the differential unevolved subhalo mass function per halo for `mass` [$M_\odot$] subhalos in `massHost` [$M_\odot$] hosts at `time` [Gyr]. Must have the following interface:

```
 double precision function myImplementationDifferential(self,time, mass, massHost)
  class           (unevolvedSubhaloMassFunctionClass), intent(inout) :: self
  double precision                                   , intent(in   ) :: time, mass, &
&  massHost
 end double precision function myImplementationDifferential
```

Existing implementations are:

`unevolvedSubhaloMassFunctionGiocoli2008` The halo mass function is computed from the function given by Giocoli et al. [2008].

Universe Operators

Additional implementations for universe operators are added using the `universeOperator` class. The implementation should be placed in a file containing the directive:

```
!# <universeOperator name="universeOperatorMyImplementation">
!# <description>A short description of the implementation.</description>
!# </universeOperator>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `universeOperatorMyImplementation`. The file *must* define a type that extends the `universeOperatorClass` class (or extends another type which is itself an extension of the `universeOperatorClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`operate` Operate on the universe. Must have the following interface:

```
subroutine myImplementationOperate(self,universe_)
 class(universeOperatorClass), intent(inout) :: self
 type (universe             ), intent(inout) :: universe_
end subroutine myImplementationOperate
```

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (universeOperatorClass), intent(inout)           :: self
 logical                       , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (universeOperatorClass), intent(inout)           :: self
 type   (inputParameters      ), intent(inout)           :: descriptor
 logical                       , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(universeOperatorClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (universeOperatorClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (universeOperatorClass)                            , intent(inout) :: self
 type     (varying_string       ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                 )                            , intent(in   ) :: &
&  sourceName
 end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(universeOperatorClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(universeOperatorClass), intent(inout) :: self
 class(universeOperatorClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (universeOperatorClass), intent(inout) :: self
 integer                       , intent(in   ) :: stateFile
 type   (fgsl_file            ), intent(in   ) :: fgslStateFile
 integer(c_size_t             ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`universeOperatorIdentity` An identity operator on universes.

`universeOperatorIntergalacticMediumStateEvolve` An operator on universes which attaches hooks to compute evolution of the intergalactic medium.

Virial Density Contrasts

Additional implementations for virial density contrasts are added using the `virialDensityContrast` class. The implementation should be placed in a file containing the directive:

```
!# <virialDensityContrast name="virialDensityContrastMyImplementation">
!# <description>A short description of the implementation.</description>
!# </virialDensityContrast>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `virialDensityContrastMyImplementation`. The file *must* define a type that extends the `virialDensityContrastClass` class (or extends another type which is itself an extension of the `virialDensityContrastClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (virialDensityContrastClass), intent(inout)           :: self
 logical                            , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (virialDensityContrastClass), intent(inout)           :: self
 type   (inputParameters           ), intent(inout)           :: descriptor
 logical                            , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(virialDensityContrastClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`isMassDependent` Returns true if the virial density contrast is mass-dependent. A default implementation exists. If overridden the following interface must be used:

```
logical function myImplementationIsMassDependent(self)
 class(virialDensityContrastClass), intent(inout) :: self
end logical function myImplementationIsMassDependent
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (virialDensityContrastClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (virialDensityContrastClass)                          , intent(inout) :: &
&  self
 type     (varying_string           ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*                    )                          , intent(in   ) :: &
&  sourceName
end subroutine myImplementationAllowedParameters
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationObjectType(self)
 class(virialDensityContrastClass), intent(inout) :: self
end type(varying_string) function myImplementationObjectType
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDeepCopy(self,destination)
 class(virialDensityContrastClass), intent(inout) :: self
 class(virialDensityContrastClass), intent(inout) :: destination
end subroutine myImplementationDeepCopy
```

`turnAroundOverVirialRadii` Returns the ratio of turnaround and virial radii at the given epoch. A default implementation exists. If overridden the following interface must be used:

```
double precision function myImplementationTurnAroundOverVirialRadii(self,time      , &
&  expansionFactor,collapsing)
 class           (virialDensityContrastClass), intent(inout)           :: self
 double precision                            , intent(in   ), optional :: time, &
&  expansionFactor
 logical                                     , intent(in   ), optional :: collapsing
end double precision function myImplementationTurnAroundOverVirialRadii
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (virialDensityContrastClass), intent(inout) :: self
 integer                            , intent(in   ) :: stateFile
 type   (fgsl_file                  ), intent(in   ) :: fgslStateFile
 integer(c_size_t                   ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

densityContrastRateOfChange Returns the rate of change of virial density contrast at the given epoch. Must have the following interface:

```
 double precision function myImplementationDensityContrastRateOfChange(self,mass,time   &
&     , expansionFactor,collapsing)
  class           (virialDensityContrastClass), intent(inout)           :: self
  double precision                            , intent(in   )           :: mass
  double precision                            , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                     , intent(in   ), optional :: collapsing
 end double precision function myImplementationDensityContrastRateOfChange
```

densityContrast Returns the virial density contrast at the given epoch. Must have the following interface:

```
 double precision function myImplementationDensityContrast(self,mass,time      , &
&  expansionFactor,collapsing)
  class           (virialDensityContrastClass), intent(inout)           :: self
  double precision                            , intent(in   )           :: mass
  double precision                            , intent(in   ), optional :: time, &
&  expansionFactor
  logical                                     , intent(in   ), optional :: collapsing
 end double precision function myImplementationDensityContrast
```

Existing implementations are:

virialDensityContrastSphericalCollapseMatterLambda Dark matter halo virial density contrasts based on the spherical collapse in a matter plus cosmological constant universe.

virialDensityContrastKitayamaSuto1996 Kitayama and Suto [1996] dark matter halo virial density contrasts.

virialDensityContrastFriendsOfFriends Dark matter halo virial density contrasts based on the friends-of-friends algorithm linking length.

virialDensityContrastBryanNorman1998 Bryan and Norman [1998] dark matter halo virial density contrasts.

virialDensityContrastSphericalCollapseMatterDE Dark matter halo virial density contrasts based on the spherical collapse in a matter plus dark eneryg universe.

virialDensityContrastPercolation Dark matter halo virial density contrasts based on the percolation analysis of More et al. [2011].

virialDensityContrastFixed Fixed dark matter halo virial density contrasts.

Virial Orbits

Additional implementations for virial orbits are added using the virialOrbit class. The implementation should be placed in a file containing the directive:

```
!# <virialOrbit name="virialOrbitMyImplementation">
!# <description>A short description of the implementation.</description>
!# </virialOrbit>
```

where `MyImplementation` is an appropriate name for the implemention. This file should be treated as a regular Fortran module, but without the initial `module` and final `end module` lines. That is, it may contain `use` statements and variable declarations prior to the `contains` line, and should contain all functions required by the implementation after that line. Function names should begin with `virialOrbitMyImplementation`. The file *must* define a type that extends the `virialOrbitClass` class (or extends another type which is itself an extension of the `virialOrbitClass` class), containing any data needed by the implementation along with type-bound functions required by the implementation. The following type-bound functions are required (unless inherited from the parent type):

`hashedDescriptor` Return a hash of the descriptor for this object, optionally include the source code digest in the hash. A default implementation exists. If overridden the following interface must be used:

```
type(varying_string) function myImplementationHashedDescriptor(self,includeSourceDigest&
&  )
 class  (virialOrbitClass), intent(inout)          :: self
 logical                  , intent(in   ), optional :: includeSourceDigest
end type(varying_string) function myImplementationHashedDescriptor
```

`descriptor` Return an input parameter list descriptor which could be used to recreate this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationDescriptor(self,descriptor,includeMethod)
 class  (virialOrbitClass), intent(inout)          :: self
 type   (inputParameters ), intent(inout)          :: descriptor
 logical                  , intent(in   ), optional :: includeMethod
end subroutine myImplementationDescriptor
```

`autoHook` Insert any event hooks required by this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAutoHook(self)
 class(virialOrbitClass), intent(inout) :: self
end subroutine myImplementationAutoHook
```

`stateStore` Store the state of this object to file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateStore(self,stateFile,fgslStateFile,stateOperationID)
 class  (virialOrbitClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateStore
```

`allowedParameters` Return a list of parameter names allowed for this object. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationAllowedParameters(self,allowedParameters,sourceName)
 class    (virialOrbitClass)                          , intent(inout) :: self
 type     (varying_string  ), allocatable, dimension(:), intent(inout) :: &
&  allowedParameters
 character(len=*           )                          , intent(in   ) :: sourceName
end subroutine myImplementationAllowedParameters
```

`velocityTangentialMagnitudeMean` Returns the mean of the magnitude of tangential velocity averaged over all orbits. Must have the following interface:

```
 double precision function myImplementationVelocityTangentialMagnitudeMean(self,node, &
&  host)
  class(virialOrbitClass), intent(inout) :: self
  type (treeNode        ), intent(inout) :: node, host
 end double precision function myImplementationVelocityTangentialMagnitudeMean
```

`objectType` Return the type of the object. A default implementation exists. If overridden the following interface must be used:

```
 type(varying_string) function myImplementationObjectType(self)
  class(virialOrbitClass), intent(inout) :: self
 end type(varying_string) function myImplementationObjectType
```

`velocityTangentialVectorMean` Returns the mean vector of the vector tangential velocity averaged over all orbits. Must have the following interface:

```
 double precision, dimension(3) function myImplementationVelocityTangentialVectorMean(&
&  self,node, host)
  class(virialOrbitClass), intent(inout) :: self
  type (treeNode        ), intent(inout) :: node, host
 end double precision, dimension(3) function &
&  myImplementationVelocityTangentialVectorMean
```

`orbit` Returns an orbit object. Must have the following interface:

```
 type(keplerOrbit) function myImplementationOrbit(self,node               , host,&
&  acceptUnboundOrbits)
  class  (virialOrbitClass), intent(inout) :: self
  type   (treeNode        ), intent(inout) :: node, host
  logical                  , intent(in   ) :: acceptUnboundOrbits
 end type(keplerOrbit) function myImplementationOrbit
```

`deepCopy` Perform a deep copy of the object. A default implementation exists. If overridden the following interface must be used:

```
 subroutine myImplementationDeepCopy(self,destination)
  class(virialOrbitClass), intent(inout) :: self
  class(virialOrbitClass), intent(inout) :: destination
 end subroutine myImplementationDeepCopy
```

`velocityTotalRootMeanSquared` Returns the square root of the mean of the squared total velocity averaged over all orbits. Must have the following interface:

```
 double precision function myImplementationVelocityTotalRootMeanSquared(self,node, host)
  class(virialOrbitClass), intent(inout) :: self
  type (treeNode        ), intent(inout) :: node, host
 end double precision function myImplementationVelocityTotalRootMeanSquared
```

`densityContrastDefinition` Returns a `virialDensityContrast` object describing the virial density contrast used to define this orbit class. Must have the following interface:

```
 class(virialDensityContrastClass) function myImplementationDensityContrastDefinition(&
&  self)
  class(virialOrbitClass), intent(inout) :: self
 end class(virialDensityContrastClass) function &
&  myImplementationDensityContrastDefinition
```

`stateRestore` Restore the state of this object from file. A default implementation exists. If overridden the following interface must be used:

```
subroutine myImplementationStateRestore(self,stateFile,fgslStateFile,stateOperationID)
 class  (virialOrbitClass), intent(inout) :: self
 integer                  , intent(in   ) :: stateFile
 type   (fgsl_file       ), intent(in   ) :: fgslStateFile
 integer(c_size_t        ), intent(in   ) :: stateOperationID
end subroutine myImplementationStateRestore
```

Existing implementations are:

`virialOrbitBenson2005` Virial orbits using the Benson [2005] orbital parameter distribution. See §12.51.2.

`virialOrbitWetzel2010` Virial orbits using the Wetzel [2010] orbital parameter distribution. See §12.51.2.

`virialOrbitJiang2014` Virial orbits using the Jiang et al. [2014] orbital parameter distribution. See §12.51.2.

`virialOrbitFixed` Virial orbits assuming fixed orbital parameters. See §12.51.2.

`virialOrbitSpinCorrelated` A virial orbit class which assigns infall directions and tangential velocities directions to an orbit return by another virial orbit class such that the orbital angular momentum of the satellite is correlated with the spin vector of the host. Specifically, the angle, θ, between the orbital angular momentum of the satellite and the spin of the host is assumed to be distributed such that $P(\cos\theta) = (1 + \alpha|\lambda|\cos\theta)/2$, where $|\lambda|$ is the magnitude of the host halo spin, and α is a parameter.

`virialOrbitIsotropic` Virial orbits which assumes an isotropic distribution of infall directions and tangential velocities applied to another virial orbit class.

Accretion Disks

Additional methods for accretion disk properties can be added using the `accretionDisksMethod` directive. The directive should contain a single argument, giving the name of a subroutine to be called to initialize the method. For example, the `Shakura-Sunyae` method is described by a directive:

```
!# <accretionDisksMethod>
!#  <unitName>Accretion_Disks_Shakura_Sunyaev_Initialize</unitName>
!# </accretionDisksMethod>
```

Here, `Accretion_Disks_Shakura_Sunyaev_Initialize` is the name of a subroutine which will be called to initialize the method. The initialization subroutine must have the following form:

```
 subroutine Method_Initialize(accretionDisksMethod,Accretion_Disk_Radiative_Efficiency_Get,Black_Hole_S
   implicit none
   type(varying_string),          intent(in)    :: accretionDisksMethod
   procedure(),          pointer, intent(inout) :: Accretion_Disk_Radiative_Efficiency_Get,Black_Hole_S
```

```
    if (accretionDisksMethod == 'myMethod') then
       Accretion_Disk_Radiative_Efficiency_Get => My_Accretion_Disk_Radiative_Efficiency_Get
       Black_Hole_Spin_Up_Rate_Get             => My_Black_Hole_Spin_Up_Rate_Get
       Accretion_Disk_Jet_Power_Get            => My_Accretion_Disk_Jet_Power_Get
    end if
    return
  end subroutine Method_Initialize
```

where `myMethod` is the name of this method as will be specified by the `accretionDisksMethod` input parameter. The procedure pointers `Accretion_Disk_Radiative_Efficiency_Get`, `Black_Hole_Spin_Up_Rate_Get` and `Accretion_Disk_Jet_Power_Get` must be set to point to functions which return the radiative efficiency, black hole spin up rate and jet power for the accretion disk respectively as described below. The initialization subroutine should perform any other tasks required to initialize the module (such as reading parameters etc.).

The radiative efficiency function must have the form:

```
 double precision function My_Accretion_Disk_Radiative_Efficiency_Get(thisNode,massAccretionRate)
    implicit none
    type(treeNode),   intent(inout), pointer :: thisNode
    double precision, intent(in)             :: massAccretionRate
    .
    .
    .
    return
 end function My_Accretion_Disk_Radiative_Efficiency_Get
```

The function must return the radiative efficiency for the accretion disk in `thisNode`. The black hole spin function must have the form:

```
 double precision function My_Black_Hole_Spin_Up_Rate_Get(thisNode,massAccretionRate)
    implicit none
    type(treeNode),   intent(inout), pointer :: thisNode
    double precision, intent(in)             :: massAccretionRate
    .
    .
    .
    return
 end function My_Black_Hole_Spin_Up_Rate_Get
```

The function must return the spin-up rate for the black hole in `thisNode` given the `massAccretionRate`. The jet power function must have the form:

```
 double precision function My_Accretion_Disk_Jet_Power_Get(thisNode,massAccretionRate)
    implicit none
    type(treeNode),   intent(inout), pointer :: thisNode
    double precision, intent(in)             :: massAccretionRate
    .
    .
    .
    return
 end function My_Accretion_Disk_Jet_Power_Get
```

The function must return (in units of $M_\odot$ (km/s)^2 Gyr^{-1}) the jet power for the black hole/accretion disk system in `thisNode` given the `massAccretionRate`.

Currently defined accretion disk methods are:

`Shakura-Sunyaev` Computes the properties of a thin, radiatively efficiency accretion disk.

`ADAF` Computes the properties of an ADAF using the model of Benson and Babul [2009].

`switched` Select either `Shakura-Sunyaev` or `ADAF` accretion disks based on the accretion rate:

$$\begin{aligned} \dot{m}_{\rm minimum} < \dot{M}_{\bullet,0}/\dot{M}_{\rm Eddington} < \dot{m}_{\rm maximum} &\rightarrow \text{Shakura-Sunyaev} \\ \text{otherwise} &\rightarrow \text{ADAF}, \end{aligned} \tag{16.10}$$

where $\dot{m}_{\rm minimum}$=`accretionRateThinDiskMinimum` and $\dot{m}_{\rm maximum}$=`accretionRateThinDiskMaximum` are input parameters.

`eddingtonLimited` Assumes no specific disk structure, instead setting the radiative efficiency to a fixed number and the jet power to a fixed fraction of the Eddington luminosity.

Analysis

Additional methods for on-the-fly analysis of merger trees can be added using the `mergerTreeAnalysisTask` directive. The directive should contain a single argument, giving the name of a subroutine to be called to initialize the method. For example, the mass distributions method is described by a directive:

```
!# <mergerTreeAnalysisTask>
!#  <unitName>Galacticus_Output_Analysis_Mass_Dpndnt_Sz_Dstrbtins</unitName>
!# </mergerTreeAnalysisTask>
```

Here, `Galacticus_Output_Analysis_Mass_Dpndnt_Sz_Dstrbtins` is the name of a subroutine which will be called to perform the analysis. The analysis subroutine must have the following form:

```
subroutine Tree_Analyze(thisTree,thisNode,iOutput,mergerTreeAnalyses)
  implicit none
  type            (mergerTree    ), intent(in   )                 :: thisTree
  type            (treeNode      ), intent(inout), pointer        :: thisNode
  integer                          , intent(in   )                 :: iOutput
  type            (varying_string), intent(in   ), dimension(:  ) :: mergerTreeAnalyses
  .
  .
  .
  return
end subroutine Method_Initialize
```

This function will be called once for each node in each tree being output. The function is passed the merger tree object as `thisTree`, along with a pointer to the node to be analyzed as `thisNode`. Additionally, the current output number is passed as `iOutput`. Finally, a list of analyses that were requested (by user input) to be performed is given in the `mergerTreeAnalyses` array. The function should check if one or more of the entries in `mergerTreeanalyses` correspond to analyses that it performs. (Note that this need only be done on the first call to this function—the values of `mergerTreeAnalyses` will not change between calls.) If an analysis is matched in this way it should be performed. Typically, an analysis function might accumulate the results of analysis and then finalize and output them prior to completion of the Galacticus model through the use of a `hdfPreCloseTask` (see §16.4.3).

Currently defined merger tree analysis methods are (see §4.4):

mass functions Constructs mass functions for a variety of different surveys. Currently supported analysis names are: `sdssStellarMassFunctionZ0.07`, `alfalfaHiMassFunctionZ0.00`, `primusStellarMassFunctionZ0.100`, `primusStellarMassFunctionZ0.250`, `primusStellarMassFunctionZ0.350`, `primusStellarMassFunctionZ0.450`, `primusStellarMassFunctionZ0.575`, `primusStellarMassFunctionZ0.725`, and `primusStellarMassFunctionZ0.900` Each such analysis is defined internally to this module through the appropriate redshift, binning, random and systematic errors, and arbitrary mapping of component masses into observed masses. The covariance matrix of the mass function is also computed (see §9.5.3 for details).

mass-dependent size distributions Constructs a two-dimensional histogram of galaxy sizes in bins of stellar mass. Currently supported analyses are `sdssSizeFunctionZ0.07`. Each such analysis is defined internally to this module through the appropriate redshift, binning, random and systematic errors, and arbitrary mapping of component masses/radii into observed masses/radii. The covariance matrix of the size function is also computed (see §9.5.3 for details).

Radiation Components

Radiation components (i.e. types of radiation field that may be added to any radiation object; see §16.5.3) are defined using a combination of several directives: `radiationLabel`, `radiationSet`, `radiationTemperature` and `radiationFlux`. For example, the cosmic microwave background radiation component is defined by the following set of directives:

```
!# <radiationLabel>
!#  <label>CMB</label>
!# </radiationLabel>

!# <radiationSet>
!#  <unitName>Radiation_Set_CMB</unitName>
!#  <label>CMB</label>
!# </radiationSet>

!# <radiationTemperature>
!#  <unitName>Radiation_Temperature_CMB</unitName>
!#  <label>CMB</label>
!# </radiationTemperature>

!# <radiationFlux>
!#  <unitName>Radiation_Flux_CMB</unitName>
!#  <label>CMB</label>
!# </radiationFlux>
```

The first of these, `radiationLabel`, should contain a single element, `label`, which gives a label that will be used to identify this component, both in other directives and also in the internal parameters used to select this radiation component (e.g. in this case, a parameter `radiationTypeCMB` will be available within Galacticus to select the cosmic microwave background component). The other directives must all specify the same `label` element and additional give, in a `unitName` element, the name of a function/subroutine to be called to perform the relevant calculation.

The `radiationSet` directive must specify a subroutine with the following template:

```
subroutine Radiation_Set(componentMatched,thisNode,radiationProperties)
 implicit none
 logical,          intent(in)                                  :: componentMatched
```

```
 type(treeNode),   intent(inout), pointer                   :: thisNode
 double precision, intent(inout), allocatable, dimension(:) :: radiationProperties

 if (.not.componentMatched) return
 .
 .
 .
 return
end subroutine Radiation_Set
```

If `componentMatched` is true, then the subroutine should set the radiation component, otherwise it should exit immediately. If the radiation component is to be set, then the routine can allocate the `radiationProperties` array as necessary to store any data needed to specify the radiation field. These data should then be set using, if necessary, any relevant information from `thisNode`.

The `radiationTemperature` directive should specify a subroutine with the following template:

```
subroutine Radiation_Temperature(requestedType,ourType,radiationProperties,radiationTemperature,radiat
 implicit none
 integer,          intent(in)                           :: requestedType,ourType
 double precision, intent(in),              dimension(:) :: radiationProperties
 double precision, intent(inout)                        :: radiationTemperature
 integer,          intent(in),    optional, dimension(:) :: radiationType

 if (requestedType /= ourType) return
 if (present(radiationType)) then
    if (all(radiationType /= ourType)) return
 end if
 .
 .
 .
 return
end subroutine Radiation_Temperature
```

The tests in the above should always be included so that the subroutine exits immediately if the component type is not active or not requested. Once these tests have been made, the subroutine should set the temperature (in units of Kelvin) of the radiation field (if applicable).

The `radiationFlux` directive should specify a subroutine with the following template:

```
subroutine Radiation_Flux(requestedType,ourType,radiationProperties,wavelength,radiationFlux,radiatio
  implicit none
  integer,          intent(in)                           :: requestedType,ourType
  double precision, intent(in)                           :: wavelength
  double precision, intent(in),              dimension(:) :: radiationProperties
  double precision, intent(inout)                        :: radiationFlux
  integer,          intent(in),   optional, dimension(:) :: radiationType

  if (requestedType /= ourType) return
  if (present(radiationType)) then
     if (all(radiationType /= ourType)) return
  end if
  .
```

```
    .
    .
    return
  end subroutine Radiation_Flux
```

The tests in the above should always be included so that the subroutine exits immediately if the component type is not active or not requested. Once these tests have been made, the subroutine should add the flux (in units of ergs cm^2 s^{-1} Hz^{-1} ster^{-1}) at the specified `wavelength` (in units of Å) of the radiation field to that in `radiationFlux`.

Currently defined radiation component types are:

`null` A null component with no radiation.

`CMB` The cosmic microwave background, assumed to be a perfect blackbody spectrum with a temperature equal to `[T_CMB]`$(1+z)$.

`IGB` The intergalactic background light, set using the method selected by `[radiationIntergalacticBackgroundMethod]`; see §16.4.1.

Radiation Components: Intergalactic Background

Additional methods for the intergalactic background radiation component can be added using the `radiationIntergalacticBa` directive. The directive should contain a single argument, giving the name of a subroutine to be called to initialize the method. For example, the `file` method is described by a directive:

```
!# <radiationIntergalacticBackgroundMethod>
!#  <unitName>Radiation_IGB_File_Initialize</unitName>
!# </radiationIntergalacticBackgroundMethod>
```

Here, `Radiation_IGB_File_Initialize` is the name of a subroutine which will be called to initialize the method. The initialization subroutine must have the following form:

```
  subroutine Method_Initialize(radiationIntergalacticBackgroundMethod,Radiation_Set_Intergalactic_Backgr
    implicit none
    type(varying_string),          intent(in)    :: radiationIntergalacticBackgroundMethod
    procedure(),          pointer, intent(inout) :: Radiation_Set_Intergalactic_Background_Do,Radiation_

    if (radiationIntergalacticBackgroundMethod == 'myMethod') then
      Radiation_Set_Intergalactic_Background_Do  => My_Method_Set
      Radiation_Flux_Intergalactic_Background_Do => My_Method_Flux
    end if
    return
  end subroutine Method_Initialize
```

where `myMethod` is the name of this method as will be specified by the `radiationIntergalacticBackgroundMethod` input parameter. The procedure pointers `Radiation_Set_Intergalactic_Background_Do` and `Radiation_-Flux_Intergalactic_Background_Do` must be set to point to subroutines which set the radiation field and return its flux as described below. The initialization subroutine should perform any other tasks required to initialize the module (such as reading parameters etc.).

The set subroutine must have the form:

```
  subroutine My_Method_Set(thisNode,radiationProperties)
    implicit none
```

```
    type(treeNode),   intent(inout), pointer                   :: thisNode
    double precision, intent(inout), allocatable, dimension(:) :: radiationProperties

    return
  end subroutine My_Method_Set
```

and should set the radiation component as described in §16.4.1. The flux subroutine must have the form:

```
   subroutine My_Method_Flux(radiationProperties,wavelength,radiationFlux)
    implicit none
    double precision, intent(in)                 :: wavelength
    double precision, intent(in),   dimension(:) :: radiationProperties
    double precision, intent(inout)              :: radiationFlux

    return
   end subroutine My_Method_Flux
```

and should increment `radiationFlux` as described in §16.4.1.

Currently defined intergalactic background radiation methods are:

`file` The intergalatic background radiation field, specified as a function of cosmic time, is read from a file. The flux is determined by linearly interpolating to the required time and wavelength. The XML file to read is specified by `[radiationIGBFileName]`. An example of the required file structure is:

```

    <datum>1.875E-39</datum>
    <datum>7.583E-38</datum>
    .
    .
    .
    <redshift>0</redshift>
    <units>erg cm^-2 s^-1 Hz^-1 sr^-1</units>
  </spectra>
</spectrum>
```

The optional `URL`, `description`, `reference` and `source` elements can be used to give the provenance of the data. The `wavelengths` element should contain a set of `datum` elements each containing a wavelength (in increasing order) at which the spectrum will be tabulated. Wavelengths must be given in Angstroms. Multiple `spectra` elements can be given, each specifying the spectrum at a redshift as given in the `redshift` element. Each `spectra` element must contain an array of `datum` elements that gives the spectrum at each wavelength listed in the `wavelength` element. Spectra must be in units of erg cm^{-2} s^{-1} Hz^{-1} sr^{-1}.

Tree Timing

Additional methods for tree timing (i.e. the time taken to process a given merger tree) can be added using the `timePerTreeMethod` directive. The directive should contain a single argument, giving the name of a subroutine to be called to initialize the method. For example, the `file` method is described by a directive:

```
!# <timePerTreeMethod>
!#  <unitName>Galacticus_Time_Per_Tree_File_Initialize</unitName>
!# </timePerTreeMethod>
```

Here, `Galacticus_Time_Per_Tree_File_Initialize` is the name of a subroutine which will be called to initialize the method. The initialization subroutine must have the following form:

```
subroutine Method_Initialize(timePerTreeMethod,Galacticus_Time_Per_Tree_Get)
  implicit none
  type(varying_string),          intent(in)    :: timePerTreeMethod
  procedure(),          pointer, intent(inout) :: Galacticus_Time_Per_Tree_Get

  if (timePerTreeMethod == 'myMethod') then
     Galacticus_Time_Per_Tree_Get => My_Time_Per_Tree_Get
     .
     .
     .
  end if
  return
end subroutine Method_Initialize
```

where `myMethod` is the name of this method as will be specified by the `timePerTreeMethod` input parameter. The procedure pointer `Galacticus_Time_Per_Tree_Get` must be set to point to a function which returns an estimate of the time taken (in seconds) to process a merger tree. The initialization subroutine should perform any other tasks required to initialize the module (such as reading parameters etc.).

The function must have the form:

```
 double precision function Time_Per_Tree(treeRootMass)
  implicit none
  double precision, intent(in) :: treeRootMass
  .
  .
  .
  return
 end function Time_Per_Tree
```

The function must return an estimate of the time taken (in seconds) to process a merger tree with the given `treeRootMass`.

Currently defined tree timing methods are:

`file` This method reads coefficients of a simple fitting formula for the processing time from a file, specified via the `[timePerTreeFitFileName]` parameter (see §17.2).

16.4.2. Events

Events are triggered during merger tree evolution. Examples are when a node needs to be promoted to its parent node, or when a minor node merges with its parent.

Node Promotion Events

Additional methods for node promotion (i.e. when a primary progenitor reaches its parent halo) can be added using the `nodePromotionTask` directive. The directive should contain a single argument, giving the name of a subroutine to be called to initialize the method. For example, the `basic` tree node method uses this directive as follows:

```
!# <nodePromotionTask>
!#  <unitName>Tree_Node_Basic_Promote</unitName>
!# </nodePromotionTask>
```

Here, `Tree_Node_Basic_Promote` is the name of a subroutine which will be called to perform whatever tasks are required prior to the promotion. The subroutine must have the following form:

```
 subroutine Node_Promotion_Task(thisNode)
  implicit none
  type(treeNode), pointer, intent(inout) :: thisNode
  .
  .
  .
  return
end subroutine Node_Promotion_Task
```

where `thisNode` is the node about to be promoted.

16.4.3. Tasks

Tasks are any processing which must be performed on a node as a result of some specific event (such as a merger).

Calculation Reset Tasks

Additional methods for calculation reset tasks (i.e. flagging that the properties of a node may have changed so that any calculations must be performed anew) can be added using the `calculationResetTask` directive. The directive should contain a single argument, giving the name of a subroutine to be called to perform the task. For example, the standard hot halo component adds a task as follows:

```
!# <calculationResetTask>
!#  <unitName>Tree_Node_Hot_Halo_Reset_Standard</unitName>
!# </calculationResetTask>
```

Here, `Tree_Node_Hot_Halo_Reset_Standard` is the name of a subroutine which will be called to perform whatever tasks are required. The subroutine must have the following form:

```
 subroutine Reset_Task(thisNode)
  implicit none
  type(treeNode), pointer, intent(inout) :: thisNode
  .
  .
  .
  return
end subroutine Prederivative_Task
```

where `thisNode` is the node for which derivatives will be computed. Tasks typically involve precomputing quantities that will be used in finding the derivatives or resetting the state so that stored quantities will be recomputed as needed.

Decode Property Identifier Tasks

Additional property identifier decoding tasks (i.e. determining the name of a property from a set of integer identifiers) can be added using the `decodePropertyIdentifiersTask` directive. The directive should contain a single argument, giving the name of a subroutine to be called to perform the task. For example, the Hernquist spheroid component adds a task as follows:

```
!# <decodePropertyIdentifiersTask>
!#  <unitName>Hernquist_Spheroid_Property_Identifiers_Decode</unitName>
!# </decodePropertyIdentifiersTask>
```

Here, `Hernquist_Spheroid_Property_Identifiers_Decode` is the name of a subroutine which will be called to perform the decoding task. The subroutine must have the following form:

```
 subroutine Property_Identifier_Decode_Task(propertyComponent,propertyObject,propertyIndex,matchedProp
  implicit none
  integer,              intent(in)    :: propertyComponent,propertyObject,propertyIndex
  logical,              intent(inout) :: matchedProperty
  type(varying_string), intent(inout) :: propertyName
  .
  .
  .
  return
end subroutine Property_Identifier_Decode_Task
```
